"Liberty in a new light." The new floodlighting installation for New York Harbor's famous Statue of Liberty provides an intensity of 30 footcandles for the statue itself and 15 footcandles for the base. This is accomplished by 96 1,000-watt projectors in the star-shaped parapet around the base and many smaller units at other parts of the statue; the torch is lighted by fourteen 1,000- and six 100-watt units.

INSTITUTE officers and committees are listed in complete and up-to-date form in this issue. *p. 71-76*

NOMINATIONS for A.I.E.E. 1932-3 national officers are announced, with brief biographical sketches of the nominees. *p. 52-55*

THREE-POWER electric locomotives are designed especially for use on portions of track not completely electrified. *p. 9-13*

STEAM or electric power station auxiliaries? Both sides of the argument are presented under sponsorship of the Institute's power generation committee. *p. 20-28*

MANY important advances in dielectric research were revealed at the fourth annual meeting of the committee on electrical insulation, National Research Council. *p. 30-35*

GREATER standardization in sizes and ratings of manufactured products, together with the increased application of "preferred numbers" should result in economies for both consumer and producer. *p. 14-19*

WINTER convention for 1932 soon will be here; features scheduled include "fourteen technical sessions, a variety of inspection trips and social functions, and a special program for women guests." *p. 50-51.* Most of the papers to be presented are abstracted in this issue. *p. 39-49*

CORRECTION—In "III—Insulation Material Aids Extinction of Cable Arcs" appearing in ELECTRICAL ENGINEERING for December 1931, the third from the last sentence in column one, p. 956, should have stated "In those tests where the insulation had been carefully cleaned away about 6 in. or more from the arc, the arc would then persist. In this case the arc voltage was about 100 volts, or between one-third and one-fourth as large as the value of 350 volts found when the arc was bounded closely by insulation."

# Radio Interference from Insulator Corona

**Extended laboratory tests reveal that the corona formation voltage and the initial radio interference voltage of clean, dry insulators are identical. Oscillograms show many interesting characteristics of insulator corona current and of the radio interference caused by it. Means for reducing the interference are suggested.**

By
F. O. McMILLAN
Member A.I.E.E.

Oregon State College
Corvallis, Oregon

RADIO INTERFERENCE originates on high voltage insulators from two principal causes: (1) from very small ionization or corona discharges due to overstressed air in the dielectric field; and (2) from intermittent leakage currents flowing through conducting deposits of various kinds on the insulating surfaces. Both of these causes of interference are of sufficient importance to warrant investigation. However, because the corona discharge type of interference is universally troublesome, and serious surface leakage is more or less localized in certain geographical areas which are subject to salt fogs or special industrial conditions, this investigation has been devoted to a study of interference due to corona.

The voltage gradient or stress on a dielectric transmitting dielectric flux is directly proportional to the flux density, and inversely proportional to the ease with which the insulating material transmits flux. Therefore when two dielectrics are transmitting the same dielectric flux in series, the dielectric having the lowest permittivity obviously will be subjected to the highest voltage gradient per unit thickness. The insulation of high voltage power lines consists of two dielectrics, air and some other solid insulating material such as porcelain or glass. In their practical application, these gaseous and solid materials are combined in series and parallel arrangements in the dielectric circuit.

Air and solid materials have widely different dielectric characteristics. High voltage insulator porcelain transmits dielectric flux approximately six times as readily as air and has a dielectric strength several times greater. Glass used in modern high voltage insulators has a permittivity four and one-half times that of air, and, like porcelain, also has a dielectric strength several times that of air. Because of the widely different permittivities, exceedingly careful design is necessary to use air and porcelain or air and glass in series combinations with high impressed voltages. Thin air-gaps in series with thick sections of porcelain or glass must be avoided in regions of dense dielectric flux, or failure of the air by ionization will result. This undesirable condition is found in three different places on many of the standard multi-shell pin type insulators as now designed, as follows:

1. At points where the conductor and tie wire are not in intimate contact with insulator head.
2. At the contact between the pin or thimble and the insulating material.
3. Between shells of multi-part insulators.

When insulators so designed are used on high voltage lines, the air in these regions of high voltage gradient fails due to the ionization-by-collision phenomenon. This air failure occurs very suddenly at the time the critical ionizing gradient is reached each half cycle of the alternating voltage impressed on the insulator. Because of the changed energy storage in the capacitance and inductance of the electric circuit the sudden flow of ionizing current resulting from the corona formation sets up oscillations in the electric circuit. The oscillations thus generated cover a wide band of frequencies from the lower range of audibility through the higher radio frequencies. These higher frequency radiations cause radio interference.

Laboratory tests show conclusively that radio interference from clean, high-voltage insulators is caused by corona discharges occurring at locations on the insulator where the air is ionized by excessive dielectric flux concentration. Large numbers of tests conducted in a darkened room showed that corona formation and radio interference always are coincident. To obtain this result, great care must be used in performing the tests. The radio receiving set must have high amplification, the loop antenna must be closely coupled with the circuit radiating the interference, and the corona observations made very carefully in a dark room. Obviously when the corona formation first occurs under a conductor behind a tie wire, or in the pin-hole of an insulator, it cannot be observed. Radio noise will occur coincident with this hidden corona and therefore precedes the first observable appearance of corona. The fact that

*Shells numbered from head to pin.

corona formation and radio interference are coincident was determined by a great many tests using insulators so designed and treated that the first corona occurs in locations easily observed in a darkened room. Some of these test data are shown in Table I.

## Radio Interference and Visual Corona Formation Voltages

At the time the investigation of radio interference was started, it was known that in general the interference from pin type insulators is more pronounced than that from the suspension type; also, that more interference was radiated from high voltage than from low voltage pin type insulators. For these reasons, practically all tests have been confined to pin and pedestal insulators rated at from 66 to 73 kv. The radio interference and visual corona formation voltage tests were made with apparatus connected as shown in Fig. 1. Great care was exercised to avoid extraneous interference from the testing equipment. To prevent interference from minute discharges between metallic parts in close proximity to each other, all pieces of hardware associated with the experimental apparatus were bonded carefully either to the high voltage conductor or to the ground. A polished ½-in. galvanized iron pipe (0.83 in. outside diameter) shielded at each end, was used as the conductor; this pipe was free from corona for all voltages up to 100 kv.

## Tests on Pin Insulators

A few representative determinations of the radio interference and corona formation voltages for pin insulators are given in Table I. The tabulated values show that radio interference and visible corona occur at the same value of insulator voltage except when the corona starts in locations not in view.

The unshielded insulators started radiating interference and showed visible corona at the surprisingly low voltages of from 8.0 to 12.2 kv. to neutral or approximately 25 per cent of the normal operating voltage. However, all of the shielded insulators except F-5 showed a marked improvement in the radio interference formation point, and only one insulator G-2 was free from radio interference at normal operating voltage. The lower case subscript letters (Table I) indicate insulators treated or modified as shown under the remarks in the table.

It may be observed that improvements were effected by sealing all crevices with cement or compound; the radio interference voltage was increased thereby from 32 to 123 per cent.

## Fundamentals of Preventing Insulator Radio Interference

Because of the nature of the disturbing electrical discharges on insulators there are at least three methods of attack to eliminate them. These are to:

1. Design the insulator in such a manner that no regions of overstressed air exist under normal operating conditions.
2. Provide conducting coatings to act as dielectric flux distributors at the head, in the pin-hole, and on other necessary parts.
3. Displace the overstressed air with an insulating compound dielectrically strong enough to withstand the potential.

From at least one standpoint, method 1 is the most desirable of the three because it employs no auxiliary material which may be subject to deterioration in service. This method, however, is the most radical departure from present practise and therefore probably will require a longer development period if found practicable at all. If method 2 employing a dielectric flux distributor is used, the conducting material must be in such intimate contact with the solid dielectric that all air between the conducting coating and the porcelain or glass is excluded. The use of method 3 requires that all air in regions subject to being overstressed to the ionizing point be displaced by an insulating compound.

Some difficulties are encountered in employing any of these three methods. Conducting coatings must remain at all times in intimate contact with the insulator material, and must withstand weathering, electrolysis due to leakage currents, temperature changes, and abrasion due to conductor and tie wire motion. Further such coatings must not terminate in positions that will overstress the air in other parts of the dielectric circuit, and the flashover value of the insulator must not be reduced below the required factor of safety. If insulating compound is used, it must withstand weathering, stay in place through the extremes of temperature to which it may be subjected, and not be displaced by the motion of the conductor and tie wire to the extent of impairing its effectiveness.

Although the design of a satisfactory insulator of practical proportions and which will be suitable for mass production apparently is not a simple problem, it is believed to be entirely possible to meet the requirements outlined and build an insulator entirely free from radio interference at a safe margin above its normal operating voltage.

## INSULATOR CORONA CURRENT INVESTIGATION

The magnitude and character of the corona current of high voltage insulators is of great interest and importance because these characteristics are direct indications of the radio interference radiation produced. Corona current is not easily studied because (1) it is quite small, attaining maximum values of approximately 40 microamperes for normal voltage on a standard 66-kv. insulator; (2) it is obscured by the insulator charging current which is approximately 0.4 milliampere maximum or 10 times the corona current for an insulator of this size; and (3) it has superimposed oscillations of very high frequency.

An instrument suitable for the investigation of currents of these magnitudes and characteristics must have a high sensitivity and be capable of responding faithfully to high frequencies. The device that meets these requirements most satisfactorily is the low voltage cathode ray oscillograph. Because of the low anode-cathode voltage and resulting low velocity of the electron stream, this instrument has the highest sensitivity of all of the cathode ray oscillographs; and the cathode beam diffusion due to the relative immobility of the positive focusing ions is not excessive for beam speeds of $3 \times 10^6$ cm. per sec. on the fluorescent screen.

Although the cathode ray oscillograph is well suited to the study of high frequency discharges, it will not of itself separate the corona current from the charging current. To overcome this difficulty the circuit shown in Fig. 2 was devised to balance out the charging current leaving only the corona current to produce deflection. With this circuit arrangement, it is possible by adjusting $R_1$ and $C_3$ to make the vertical deflecting potential on the oscillograph zero for all insulator voltages up to the critical corona formation voltage. At this critical voltage and for higher voltages, the oscillograph vertical deflecting voltage is proportional to the instantaneous value of the insulator corona current in $R_2$. This condition obtains because $C_1$ is free from corona. A glass insulator with dielectric flux distributing coatings on the head and in the pin-hole, and found by test to be free from corona up to 50 kv., was used for $C_1$ when the accompanying cathode ray oscillograms were taken.

The horizontal deflecting or sweeping voltage for the oscillograph was obtained from a neon oscillator connected as shown in Fig. 2. This type of oscillator produces practically a straight line time axis that can be operated over a wide range of sweeping frequencies by the adjustment of $R_3$ and $C_4$. This sweeping oscillator can be synchronized readily with the frequency producing the phenomena under observation so that a stationary image either for observation or recording photographically is obtained. To eliminate stray dielectric fields a grounded wire cage 5x5x6 ft. high was used to shield all apparatus associated with the oscillograph and neon oscillator.

Voltage was applied to the laboratory line and increased to a value just below the critical corona voltage for the insulator under test. At this voltage,

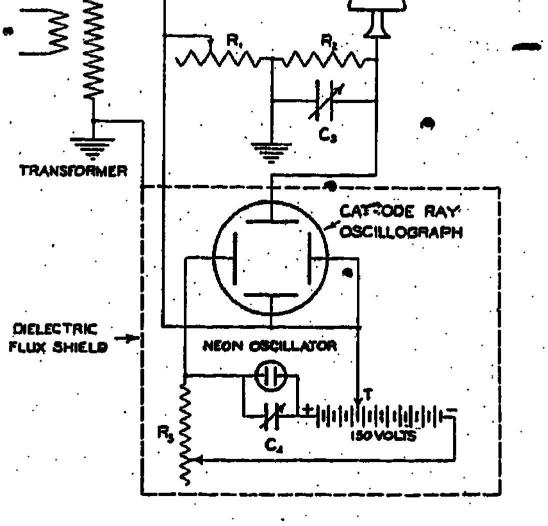

Fig. 2. Circuit for obtaining cathode ray oscillograms of insulator corona current. Note that the insulator charging current is balanced out

resistance $R_1$ and capacitance $C_3$ were adjusted to make the vertical deflecting voltage zero. These adjustments were made while the neon oscillator was sweeping the cathode beam over the time axis, conditions under which any slight inaccuracies in balance were detected readily by the deviation of the beam from a straight line. When this balance was established accurately, a series of corona current oscillograms was taken for the insulator at various conductor to pin voltages from 10 to 40 kv., r.m.s., in increments of 5 kv.

In Fig. 4 is shown a series of corona current oscillograms taken on a standard three-shell 66-kv. porcelain insulator with a ¾-in. malleable thimble cemented in the pin-hole. Oscillogram *G* (40 kv.) shows the normal corona current for this insulator operating on a three-phase transmission line at a line potential of 69.3 kv. Atmospheric conditions were representative and normal, air density being 1.006 and the absolute humidity 9.4 g. per cubic meter.

Oscillograms reproduced in Fig. 5 show that when the ionization gradient is reached, the current rises to a maximum value quite abruptly during the positive half cycle and decays rapidly with considerable oscillation, reaching zero practically coincident with the occurrence of maximum voltage on the insulator. During the negative half cycle the corona current does not reach its maximum value in so short a time interval as in the positive half cycle, the oscillations appear to be much more violent, and the corona current is sustained at a high value for a longer time. The higher sustained value of negative current is shown clearly by the fact that for the same line voltage the area under the negative wave is greater than under the positive wave.

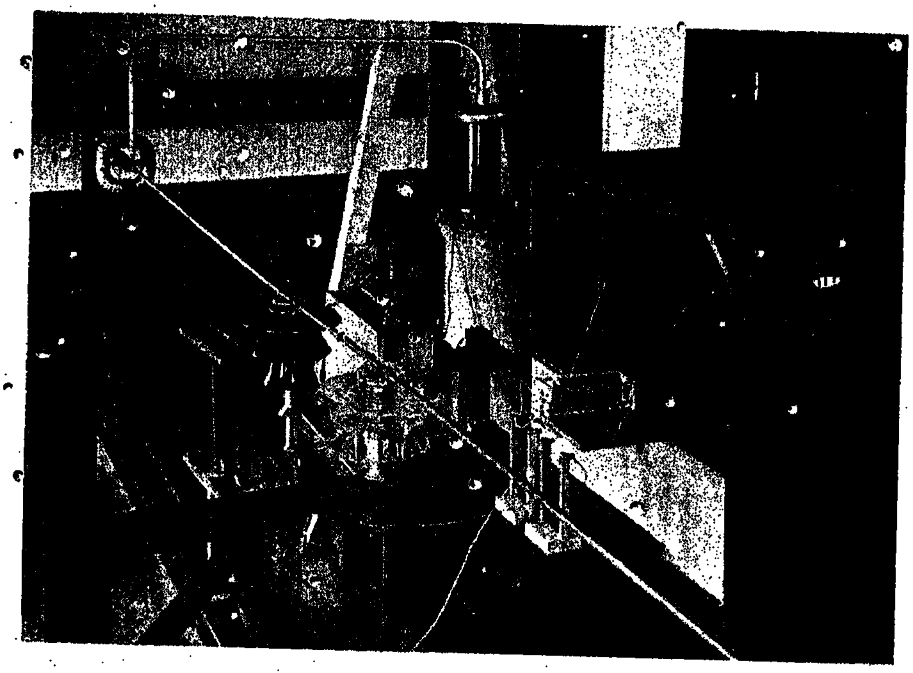

Fig. 3. Apparatus for obtaining cathode ray oscillograms of insulator corona current

Unfortunately the oscillograms do not show the oscillations clearly. This is because that in order to form an image on photographic film it is necessary to trace several successive cycles of corona current on the fluorescent screen. On account of the chance character of corona formation, successive cycles of corona current are not alike, and where the oscillations are the greatest, the variation in successive figures is largest. This variation in the registration of successive cycles is shown on the oscillogram by variations in intensity of exposure and sharpness of the image.

Corona current oscillograms were taken also on a special three-shell 66-kv. porcelain insulator with a silver and bismuth coating on the head and in the pin-hole. This insulator (No. B-6 of Table I) was practically identical with the previous one except for the addition of the metallic coatings. In this case no corona current was observed below 30 kv. The difference in the character of positive and negative corona currents on this insulator was greater than for the standard insulators. The positive current shows much less oscillation than the negative, and the duration of the positive current was observed to be much shorter than that of the negative.

Metallic dielectric flux distributors on this special insulator greatly improved the characteristics from the standpoint of radio interference. The interference starting voltage was increased from slightly above 10 kv. to 23.5 kv., and the maximum corona current at 40 kv. was reduced from 40 to 11 microamperes. However, the voltage gradient was noted to be excessive at the edges of the metallic coatings on the head and in the pin-hole at 23.5 kv., which is only 61.6 per cent of normal operating voltage.

Similar oscillograms were taken for a standard 70-kv. one-piece glass insulator without any treatment to prevent corona formation. These oscillograms show the same general corona current characteristics obtained with the standard porcelain insulator. Cathode ray oscillograms for a similar glass insulator with high resistance iridescent dielectric flux distributors on the head and in the pin-hole revealed no corona current for voltages up to 40 kv. when these coatings were in good condition.

## OSCILLOGRAPHIC STUDY OF RADIO RECEIVER OUTPUT

In order to determine the value of the cathode ray oscillograms of insulator corona currents for indicating the interfering noise that will be produced in a radio receiver, a large number of both Duddell and cathode ray oscillograms was taken of the audio frequency output from a superheterodyne receiver. These were taken with the receiver tuned for a frequency of 1,000 kc. and receiving only the radiation from the laboratory line equipped with one insulator. The circuit conditions and voltages used were the same as those employed when the cathode ray oscillograms of corona current discussed previously were taken.

A typical set of oscillograms for this portion of the investigation may be seen in Fig. 5. In these the polarity and magnitude of the insulator voltage as well as the audio frequency current output of the radio receiver are shown for the standard, three-shell, 66-kv. porcelain insulator for which corona current oscillograms were shown in Fig. 4. It should be observed that the oscillations in the audio output have frequencies reaching values of 5,000 cycles per sec., which is the natural period of oscillation for the oscillograph vibrator element. Therefore the amplitude indications are not very reliable. Notwithstanding this fact, the oscillograms show accurately the beginning of the corona discharge and quite accurately the end of the corona discharge with reference to each half cycle of the insulator voltage. At 14.1 kv. maximum, there is just the slightest trace of interference, occurring at practically the crests of the voltage waves. At 21.2 kv. maximum, the corona starts at a very small electrical angle and at 28.3 kv. maximum, it appears at the zero point of the voltage wave. For higher voltages the corona starts before the voltage wave reverses polarity. For all values of voltage the corona discharge stops at the crest of the voltage wave. This is shown by the fact that at that point the oscillations stop. At the higher voltages the smooth decay of current following the oscillations is due to the recovery of the receiving set from overloading.

The phenomenon of obtaining critical ionizing voltage gradients on the insulator at zero, and even with opposing conductor potentials, is due to the large space charge established in the space and on the insulator surface surrounding the conducting materials where ionization has taken place during the previous half cycle. This is brought out in greater detail in the following discussion.

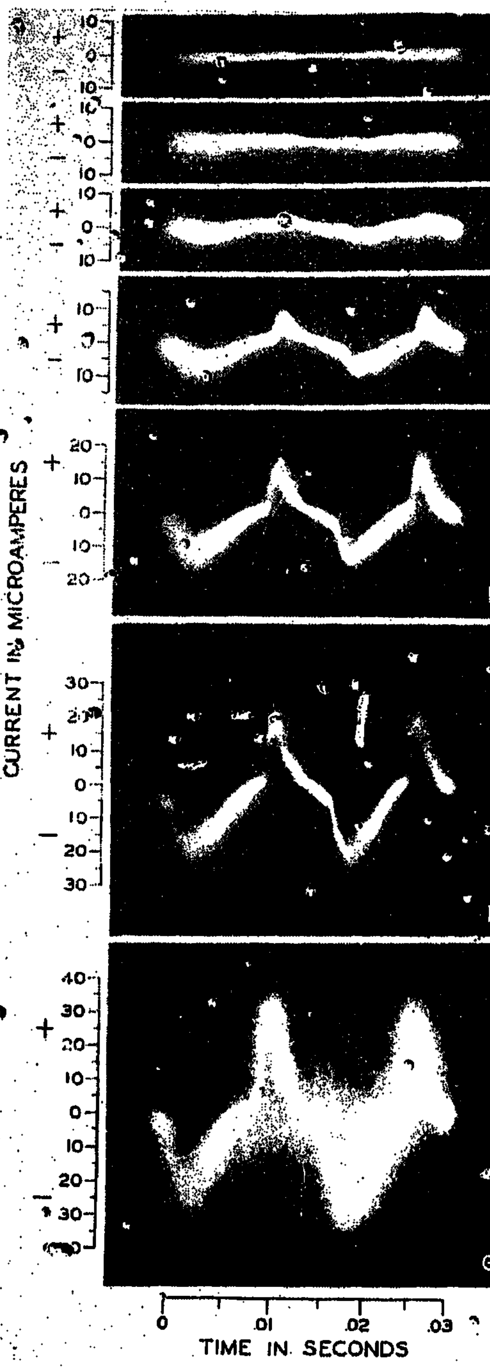

**Fig. 4. Cathode ray oscillograms of corona current for a standard 66-kv. porcelain pin type insulator**

## A THEORY OF THE FORMATION OF INSULATOR CORONA

A theory of the phenomena associated with corona formation on an insulator can be developed by assuming the initial half cycle of conductor voltage to be either positive or negative. For the following discussion the initial polarity is assumed to be negative and the ionization of the air surrounding the conducting parts and in zones of high voltage stress is assumed to be only the normal atmospheric value at the instant the voltage first is applied.

During the initial negative half cycle, the dielectric field of the negatively charged conductor repels the free electrons and negative ions in the regions of high voltage gradient; when the critical ionizing voltage gradient is reached, they bombard the air molecules with such violence that ionization by collision results. The additional electrons and negative ions produced by collision are repelled from the conducting material by the electric field, and form the major part of an outside negative space charge. The heavy immobile positive ions move relatively slowly toward the conductor in the regions of ionization. In this manner corona increases and the positive ion space charge that accumulates due to the relative immobility of the positive ions subtracts from the negative field of the conductor until the crest of the voltage wave is reached. At this point ionization stops because the space occupied by the corona is completely ionized; the voltage gradient at the outside boundary of the corona discharge is just equal to the critical value and must decrease below this value as the conductor voltage decreases. For the negative conductor condition under consideration the positive space charge limits the corona to a comparatively small discharge distance. Many of the free electrons are swept out of the ionization zone and the loss of positive ions by recombination adjacent to the conductor thereby is reduced to a relatively small number. Large numbers of positive ions always are present therefore adjacent to the conductor; this is such a favorable position that a comparatively small

positive space charge will reduce greatly the field of a large negative conductor voltage at the outside boundary of the corona discharge.

After the negative voltage wave passes the crest and starts to decrease, the negative space charge at the outer boundary of the corona no longer is replenished by new ionization; hence it begins to diffuse and be lost by recombination. This action releases the positive space charge and allows it to move more rapidly back toward the conductor, which movement tends to increase the gradient in the space between the positive space charge and the conductor. Because of the decrease in conductor potential, ionizing voltage gradients prior to actual reversal of conductor potential are reached only when the space charge is very large. The latter phenomenon does occur, however, for all maximum applied voltages in excess of approximately twice the maximum visual critical corona voltage.

When the conductor voltage reverses and becomes positive after the described phenomena have taken place, the dielectric flux of the residual positive space charge adds to the field of the positive potential on the conductor. The addition of those fluxes causes the critical ionizing voltage gradient to occur at lower and lower values of instantaneous positive conductor voltages as the maximum conductor voltage is increased above the visual critical corona value. The resultant positive field accelerates the electrons in the surrounding space, and when high velocity collisions occur with molecules of air, ionization is produced. Large numbers of the electrons liberated are swept from the field and removed by the conductor, leaving more immobile positive ions to add to the positive space charge. This increase in space charge increases the dielectric flux density and extends the ionizing voltage gradient to a far greater distance from the conductor than would be possible with the conductor voltage acting alone. When the crest of the positive voltage wave is reached, the voltage gradient is at maximum and the corona discharge stops because the space occupied by the corona is completely ionized; the decrease in the conductor voltage makes ionization at a greater distance from the conductor impossible. As the conductor potential decreases it drops below space charge potential and a field is established between space charge and conductor. The field produces ionizing voltage gradients before the conductor voltage reverses, when the space charge potentials are very high. This phenomenon occurs for maximum applied voltages in excess of approximately twice the maximum visual critical corona voltage.

During the rise in voltage on the positive half cycle a much larger positive space charge is established than that produced during the same period of the negative half cycle. This is because when the conductor is positive, the positive space charge flux adds to the conductor field and extends the ionization gradient, when it is negative, the positive space charge flux subtracts from the negative conductor field at the outside corona boundary.

When the conductor voltage reverses and becomes negative following the establishment of a large positive space charge in the manner just described, a very high voltage gradient is produced between the negative conductor and the residual positive space charge because of the very short distance between them. When this voltage gradient reaches the critical ionizing value (which may occur before the voltage actually becomes negative) breakdown occurs in the form of minute arcs which neutralize the space charge. These corona arcs produce sudden changes in the electric circuit conditions, thereby causing high frequency oscillations of a violent character.

## Radio Interference from Positive and Negative Corona

Near the critical corona formation voltage the electric circuit oscillations and the electromagnetic radiation resulting from them are inherently much worse for 60-cycle a-c. circuits when the conductor is negative than when it is positive. Theoretical considerations outlined in the preceding paragraphs indicate that this condition is to be expected and experimental investigations show a very decided polarity effect under certain conditions. For the special 66-kv. porcelain insulator with silver and bismuth coatings on the head and in the pin-hole, oscillograms taken show a very striking polarity effect in the interference radiation. (See Fig. 6.)

From the experimental investigations it appears that the marked difference in radio interference when the line is positive and when it is negative, respectively, can be observed only when the insulator has a definite critical corona formation voltage. When the voltage is increased far above this critical value, the polarity effect becomes less marked and at still higher voltages probably would disappear almost entirely. This phenomenon accounts for the fact that practically no interference polarity effect was observable in the tests on standard insulators. (See Fig. 4.) On such insulators there is a heterogeneous group of visual critical voltage gradients that cause corona to form in small areas at various locations for every different value of insulator voltages from approximately 25 per cent normal operating voltage up to the flashover value. There the polarity effect is obscured because when sufficient voltage is applied to produce appreciable corona on the insulator, the regions that go into corona at low voltage are subjected to an excessive voltage gradient and therefore produce practically the same interference on both positive and negative half cycles.

## SUMMARY

The findings of this study may be summarized as follows:

1. Standard multi-shell pin type insulators of conventional design are susceptible to corona formation at three different points.

2. Radio interference and visible corona formation for clean insulators start at the same voltage.

3. Radio interference from insulator corona may be reduced by (a) designing the insulator so as to eliminate regions of overstressed air; (b) providing conducting coatings on different parts to act as dielectric flux distributors; and (c) displacing the overstressed air with an insulating compound.

4. Insulator corona current can be separated from the charging current and studied independently by means of the cathode ray oscillograph.

5. Duddell oscillograms of the line voltage, and the audio frequency output of a radio set receiving the radiation from an insulator or other source of corona, provide an excellent means for studying certain corona characteristics.

6. The radio interference radiation from an insulator having a definite critical corona voltage shows a decided polarity effect for all corona voltages up to approximately twice the critical disruptive value.

Associate A.I.E.E.

Both of the General Elec. Co., Erie, Pa.

**Locomotives for operation from either an external distribution system or an internal power source are especially well adapted to service over portions of road which for economic reasons cannot be completely electrified. Some of the more important engineering features of this type locomotive are outlined in this article.**

THE THREE-POWER locomotive has taken its name from the fact that it may operate either from an external power source, which may be either a third-rail or overhead distribution system, or from two internal sources. The internal sources consist of a storage battery and a generator driven by an internal combustion engine. While the locomotive may be operated from the battery alone, operation on internal power usually is carried out with the generator running in parallel with the battery. The New York Central Railroad now has in service 36 locomotives of this type. These are used primarily in the elimination of steam service on the "West Side" tracks of New York City where the complete electrification with external power would be extremely impractical if not almost impossible. With the advent of electrified suburban passenger service from Hoboken, N. J., the Delaware, Lackawanna and Western Railroad also has put into service two three-power locomotives to aid in eliminating steam from its Bergen (N. J.) tunnels. These are used in a combination of transfer and switching service between that railroad's yards in Jersey City (adjacent to the Hoboken passenger terminal) and the Secaucus yards about 3.5 miles distant.

Perhaps the most outstanding feature of the three-power locomotive is its great flexibility. On both the New York Central and the Lackawanna systems the

---

Based upon "Engineering Features of Three-Power Locomotives" (No. 32-2) to be presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25-29, 1932.

service demanded a self-propelled locomotive capable of handling the heaviest type of switching and short transfer work, as well as road freight and transfer service on external power.

Service on the New York Central consists of switching and transfer work in and between yards at three different points on its New York City tracks, with many sidings leading into warehouses and industrial buildings, as well as much trackage on city streets. On the Lackawanna system the transfer work consists of hauling heavy trains at relatively high speeds on external power between the two yards mentioned previously; the switching, which must be done entirely on internal power, consists of hauling these trains into the yards, and partially breaking them up, making up outgoing trains, and hauling them to the electrified tracks. To meet needs of this character the three-power locomotive was developed.

Although the operating voltages of the two railway systems mentioned are widely different (New York Central 600 volts d-c.; Lackawanna 3,000 volts d-c.) the general characteristics and scheme of operation of both locomotives are quite similar. (See Table I.) When using external power the unit performs exactly as a straight electric locomotive although the engine-generator set may be run to charge the battery. On non-electrified tracks, power may be taken from the battery alone; however, if the engine is running, traction and auxiliary power are taken entirely from the engine-generator set up to its capacity, above which the battery automatically assumes the excess load. On light loads the engine-generator may run the locomotive and charge the battery at the same time.

GENERAL REQUIREMENTS FOR INTERNAL POWER PLANT

The average power required for switching service is small while the peak demands are relatively large. The theory upon which internal power operation of the three-power locomotive is based is that the battery will provide the excess power required for the peak demands, thereby allowing the engine size to be cut to a minimum. Extensive tests to determine the actual extent of these power requirements in heavy switching service on internal power were run in 1928 on the first New York Central locomotive built. The average output for the maximum observed day for three-shift service was approximately 500 kw-hr. which gives an average load of 62.5 kw. per eight-hour shift. The average work for 65 shifts of three-shift service was 447 kw-hr. per shift. Frequently peak loads as high as 800 kw. were recorded, which is more than twelve times the maximum observed average load per eight-hour shift.

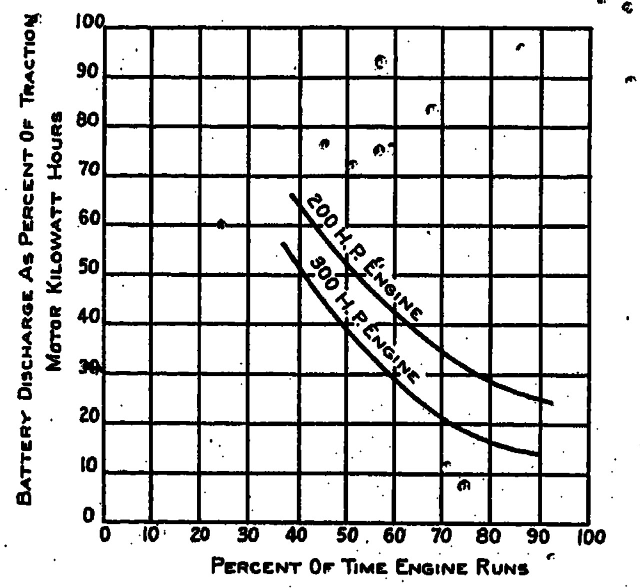

Fig. 1. Battery discharge in heavy switching service on internal power only, as a function of time that oil engine is running

In later tests made on the Lackawanna locomotives, the ratio of the average power required in switching to that required in transfer work proved to be approximately 50 kw. to 450 kw. or 1 to 9. It is believed that this is the first case where actual data have been obtained which show the relative amount of work done on the main and yard tracks. Switching service in these tests called for frequent short periods of operation at from 200 to 400 kw. with peaks of 800 kw., while transfer work had peaks as high as 3,000 kw.

For long battery life and reasonable maintenance, the battery discharge for each 24 hours the locomotive is operating in three-shift service should be limited to 125 per cent of the total capacity at the six-hour rate. To limit the battery discharge to this value successfully it is essential that the correct generator characteristic be used. This characteristic should be such as to insure the engine-generator unit carrying the entire load up to its capacity, but not to recharge the battery so rapidly that the engine must be shut down frequently to prevent overcharging. Without the engine the battery must of course supply the entire load, which results in the discharge over a 24-hr. period being considerably greater than with the engine running most of the time. Initial tests showed that the engine should be run at least 70 per cent of the time to meet these discharge limitations. However, a generator characteristic low enough to insure engine operation 70 per cent of the time is too low to give the battery an equalizing charge; therefore two generator characteristics are necessary; (1) a normal characteristic for regular operation, and (2) a higher or equalizing characteristic for use periodically to give the battery a gassing charge.

Minimum size of the battery is fixed by the traction motor characteristics and locomotive weight on one hand and speed requirements on the other. The former determine the maximum current which may be drawn from the battery as limited by adhesion, and the latter the number of cells. With traction motors in parallel the total current values for the New York Central locomotive at various adhesions range from approximately 2,500 to 3,700 amperes. A battery selected for this locomotive must be large enough to deliver these currents and to carry successfully at least 4,000 amperes for a period long enough to blow the 2,500-ampere battery fuses. Because of the decreased available capacity of the battery at high discharge rates, it is not practical to operate this type of locomotive on internal power at high adhesion and high speed for any great length of time. However, the extreme load conditions given above are possible for short periods and must be met successfully in practical operation.

In case of necessity it is possible to operate these locomotives at high adhesion over considerable distances by running at reduced speeds with the motors in series or series-parallel. In such cases the current to the motors is reduced to one-quarter or one-half of the value which would be required with the motors in parallel for the same total tractive effort. As the engine-generator set will continue to deliver its full power, all of this reduction in current is taken from the battery discharge rate, thus greatly increasing its available capacity. In addition to this, the increase in available kilowatt-hour capacity of the battery increases the duration of the movement and to this extent increases the kilowatt-hours delivered by the engine, thus further increasing available mileage. For fast and responsible operation of the locomotive it is advantageous to have the battery voltage near the rated voltage of the traction motors.

## INTERNAL POWER PLANT OF THE NEW YORK CENTRAL LOCOMOTIVE

As a result of the initial tests and the weight and speed considerations just outlined, a design for the New York Central locomotive was adopted to meet the following specifications:

Battery short time current rating—2 min.—3,000 amperes
Engine hp.—300
Assumed time engine running—85 per cent
Maximum amount battery may be discharged in 24-hr. period (125 per cent of capacity at 6-hr. rate):
812 ampere-hr. in 24 hr.
271 ampere-hr. per 8-hr. shift
114 kw-hr. per 8-hr. shift (average discharge volts 420)
See Table I also

Effect upon the battery discharge of the percentage of time the engine operates is shown in Fig. 1. These curves are plotted from data taken during the tests on the initial New York Central locomotive. For the 300-hp. curve a number of points was obtained between 45- and 75-per cent operation, the curve being extended somewhat beyond these values upon reasonable assumptions. The 200-hp. engine curve is based largely upon assumptions since only one point (93 per cent) was available from the test data, this test being made by

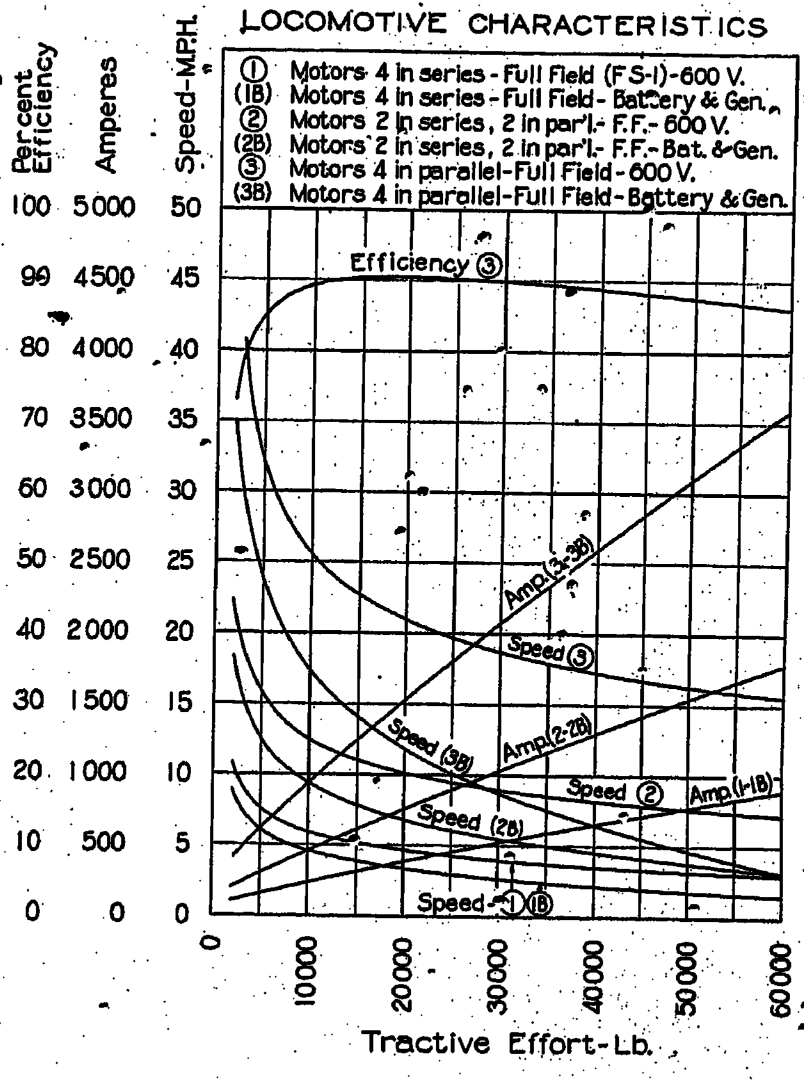

**Fig. 2. Operating characteristics of New York Central three-power locomotive**

setting the fuel finger of the oil engine governor to limit the engine output to 200 hp.

With a 300-hp. engine running 85 per cent of the time the battery discharge will be equivalent to approximately 15 per cent of the power delivered to the traction motors; therefore the maximum average work which the locomotive can do per eight-hour shift when operating three shifts per day on internal power is 114/0.15 = 760 kw-hr. Using Fig. 1 and interpolating for the 250-hp. engine, it may be shown that a 250-hp. engine might have been used successfully with the 301-kw-hr. battery to meet the requirements of 500 kw-hr. per shift. However, it was thought advisable to allow some margin for contingencies; hence a combination of a 300-hp. engine with a 301-kw-hr. battery finally was chosen because of the greater margin of capacity per shift as well as the ability to use an oil engine which had been thoroughly proved in railway service. Characteristics of this locomotive on both external and internal power are shown in Fig. 2.

The oil engine finally chosen for both the New York Central and Lackawanna locomotives is the Ingersoll-Rand 300-hp. vertical, six-cylinder, four-stroke-cycle, trunk-piston, single-acting type with direct fuel injection. The engine is controlled by a constant-speed governor which regulates between 550 r.p.m., full load, and 575 r.p.m., no load. The engine is direct-connected through a flexible coupling to a six-pole, self-excited, compound-wound, 200-kw. generator of the single-bearing type, with multiple self-ventilation.

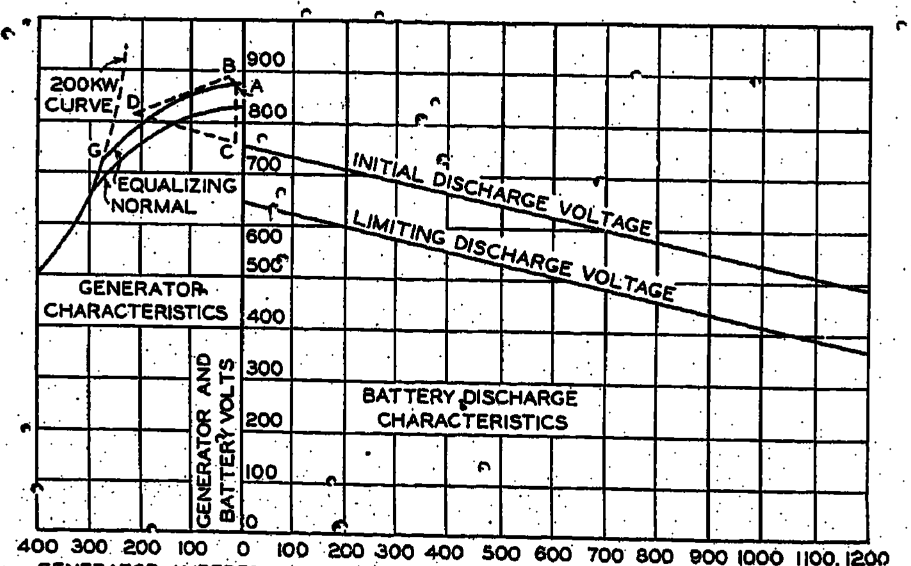

**Fig. 3. Battery and generator characteristics of Lackawanna three-power locomotive**

## SELECTION OF GENERATOR CHARACTERISTIC

In Fig. 3 are shown the generator characteristics and the battery volt-ampere charge and discharge characteristics of the internal power plant of the Lackawanna locomotive. These characteristics are representative of general three-power locomotive practise. When the battery is fully charged, any rate of charge however small will produce gassing; if the charging rate be high enough, gassing will occur with the battery in any state of charge, although the rate may be reduced during the latter part of charge to a value which, unless abnormally sustained or occurring too frequently, will produce so small an amount of gassing as to be practically harmless. This value is called the *finishing rate* and is point *B* in Fig. 3. The charging rate at the end of the charge should be confined between the finishing rate and one-half of the finishing rate. Consequently, line *AB* represents the volt-ampere charge characteristic of the battery at finish of charge condition. The ability of the battery to absorb high charging rates at the start of charge is indicated by point *D*; this is the maximum charging rate recommended; hence, line *CD* is the volt-ampere charge characteristic at start of charge. Line *DB* represents the theoretical generator characteristic which would charge the battery in the minimum time, and *AC* that which would produce a constant current charge at one-half the finishing rate; therefore, the area *ABDC* includes all values of current and voltage that may be used to charge this battery under permissible conditions, and the generator characteristic should intersect lines *AB* and *CD* and lie between lines *BD* and *AC*. The generator characteristic also is restricted by the 200-kw. output curve of the engine-generator set. To allow delivery of approximately full engine load over the whole range of battery discharge, the generator characteristic should pass near point *G* and lie close to the 200-kw. curve at voltages below *G*.

The higher generator curve in Fig. 3 meets these requirements and is suitable for giving the battery an equalizing charge, but is too high to permit the engine to run a sufficient percentage of the time to keep battery discharge within the daily limit of 125 per cent of rated capacity without overcharging. Therefore, the lower curve is used for normal charging and the higher characteristic for periodic equalizing charges.

When using the normal characteristic, the charging rate at the end of charge is less than one-half the finishing rate, but with a properly shaped characteristic and the engine running almost continuously, the battery will be maintained between equalizing charges in a satisfactory state somewhat below full charge. Use of the low generator curve for normal charging has the further advantage of allowing a margin for variation of characteristic between inspections, without the risk of overcharging the battery seriously, which might happen if the engine speed increased and the equalizing characteristic were being used in daily operation.

Control is arranged so that whenever the locomotive is operating on internal power and the traction motors are connected to the battery generator bus, the generator is transferred to the higher characteristic automatically. This is permissible because usually unless the battery is in a very low state of charge, the traction motor load is sufficient to hold the generator voltage below the point where high charging rates will occur. This arrangement permits the use of a more drooping curve without dropping the traction power characteristic below point *G*. The necessity for a drooping curve may be appreciated better when it is considered that the battery is intended to deliver only 42 per cent of its capacity per eight-hour shift, whereas a generator characteristic lying along the line *BD* would give the battery a complete charge in four hours if applied continuously from full discharge and neglecting the small auxiliary load.

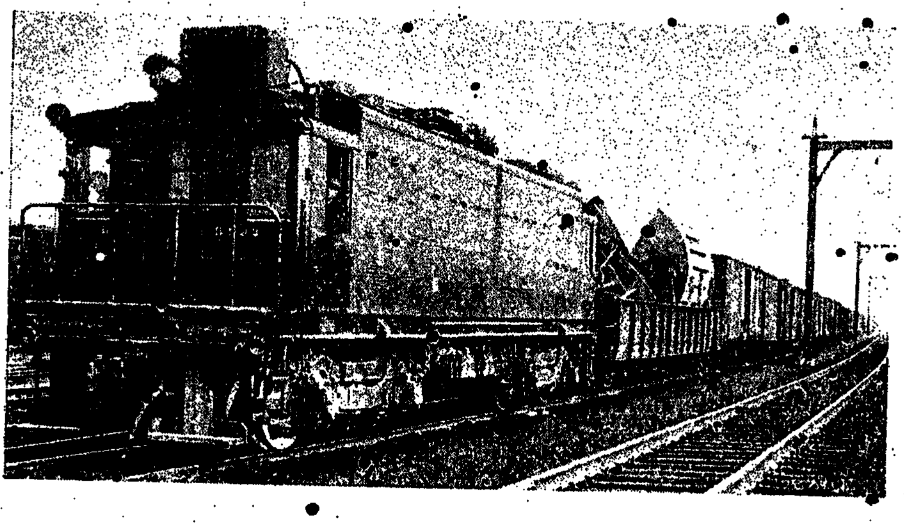

**Fig. 4. Lackawanna three-power locomotive hauling a train on internal power**

Over-all dimensions of locomotive

Length inside knuckles—48 ft. 0 in.

Height over-all (pantograph locked down)—15 ft. 2 in.
Width over-all—9 ft. 11 in.
Maximum curvature—30 deg.
Truck centers—25 ft. 10 in.

## CONTROL OF THE INTERNAL POWER PLANT

Both the New York Central and Lackawanna locomotives have a three-speed control on internal power. The series or lowest speed connection develops maximum tractive effort with minimum current from the battery generator unit, allowing most slow switching movements to be made almost entirely on the engine-generator set without using battery current.

On both locomotives transfer from external to internal power is controlled by a potential relay and is automatic upon loss of external power, although the automatic feature is selective on the New York Central locomotive because of power interruption on third rail gaps when transfer to internal power is not desired. Transfer from internal to external power is accomplished by turning the controller handle to the "off" position and then notching out, which is necessary because of going from a lower to a higher voltage power source. Indicating lights show whether operation is from internal or external power and whether collector shoes or pantograph are in contact with the third-rail or trolley-wire.

The engine is started by motoring the generator from the battery through the starting resistance, the maximum field for starting being secured by short circuiting the generator shunt-field resistance. A reverse-current relay connects the generator to the battery when the proper generator voltage has built up; likewise it disconnects the generator should the generator voltage drop below that of the battery. To give the battery its weekly gassing charge the equalizing charge switch is closed, short circuiting a section of the generator shunt-field resistance.

Fuel oil is delivered to the engine through an electrically operated valve, which, should low lubricating oil pressure or overspeed occur, is closed automatically by means of an oil pressure switch or speed limit switch, respectively. The same rheostat values are used on both internal and external power on the New York Central locomotive. Control of the battery-generator combination is practically the same on both locomotives. On the Lackawanna locomotive, however, because of the great difference between internal and external power voltages, a set of contactors is employed to rearrange the resistor steps to secure proper operation on internal power.

## AUXILIARIES

Auxiliaries on the New York Central locomotive operate automatically from the third rail when available, but on the Lackawanna locomotive these run at all times on internal power, as this scheme is simpler and less expensive than furnishing auxiliaries for 3,000-volt operation.

Operating cabs are heated by hot water from the oil-engine cooling system. When working on external power, electric immersion heaters operating from the third-rail or overhead trolley are used to heat the cooling system water for cab heating as well as to prevent freezing.

## CONCLUSION

The three-power locomotive has a field of its own and is not intended to supplant the straight oil- or gas-electric unit generally. The work of the locomotive when operating on internal power must be sufficiently intermittent to allow the battery to be maintained in a satisfactory state of charge. Heavy switching and short heavy transfer work on internal power or a combination of both, together with external power operation, offer conditions for which this type of locomotive is best suited. With its internal power feature, this locomotive approaches a universal locomotive for road freight, transfer, and switching service on sections of track which, for economic or practical reasons, could not be electrified completely.

# Standardizing Sizes and Ratings

**Marked economies may be secured by standardizing industrial products to eliminate all unnecessary sizes and ratings. Based upon a system of "preferred numbers," selection of desirable sizes may be made with reasonable accuracy through the use of algebra and geometry supplemented by judgment and common sense.**

By
R. E. HELLMUND
Fellow A.I.E.E.

Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

CONSUMERS and producers of industrial products both are vitally interested in the most economical method of standardizing the sizes and ratings of such products. The consumers are interested because they bear every item of cost entering into both the manufacture and the use of an article; the producer because he will not be successful unless he can meet the requirements of the consumer in the most economical manner. In other words, the interests of the two in this respect are identical. If further it is realized that all of us are consumers of industrial products, and that the large majority of us are involved also in one way or another in production, it is evident that the subject is of very general interest and that an early and economically correct standardization of any type of product will prove of advantage to everybody.

However, in spite of the common interests of consumer and producer and the fact that most of us are both of these, a solution of this matter frequently is delayed because there are differences of opinion regarding the best choice of sizes or ratings. Such differences usually are due to the inclination on the part of most individuals to overemphasize those points which in the absence of proper methods of analysis happen to come closest to their attention. For instance, the consumer who is in need of a certain size of article usually hesitates to buy a standard article which is available but larger than he requires, because he feels that in so doing he spends more money than is necessary to meet his requirements. He therefore insists upon the size he needs and thus creates a demand for a large number of sizes. On the other hand, the producer who is put to great expense for tools, stock-keeping, etc., when there are too many standard sizes, frequently will overemphasize the importance of standardizing on as few sizes as possible. All this results in uncertainty and confusion when sizes are selected. Further difficulties arise from the fact that at first, each manufacturer usually establishes sizes and ratings more or less independently of other manufacturers of the same articles.

Later on, but generally not until a conglomeration of sizes has been established, standardization is attempted by those interested. Such efforts are then of course greatly handicapped by the clashing of individual interests, a condition which is unavoidable because of the investments made by the various manufacturers for tools and stocks. Even if a compromise is reached after considerable effort, it is usually at great expense to some or all of those concerned; and because it is agreed upon without due consideration of the best economic results continued waste may be involved in the compromise.

For the purpose of improving the situation just described, a system of "preferred numbers" has been proposed during recent years. Unfortunately so far little use has been made of it, partly perhaps because it has not been sufficiently promulgated, but probably more because industry and the engineering profession have not yet become thoroughly aroused to the fact that this problem of properly establishing sizes and ratings is deserving of most serious consideration. As their designation indicates, these preferred numbers, are certain numbers to be used in preference to any others in selecting standard sizes and ratings. They are arranged in so-called 5, 10, 20 and 40 series, each providing uniform steps between its numbers of 60, 25, 12, and 6 per cent, respectively. Naturally the general adoption of these numbers would be a great step forward, but even after their adoption there still remains the question as to which of the standard percentage steps is the most economical in any given case.

All this indicates a certain helplessness on the part of industry and the engineering profession in this matter of establishing sizes and ratings, and it most certainly emphasizes the desirability and necessity for a more analytical and rational manner of attack upon this important problem. It is the purpose of this article to deal with the fundamentals entering into the problem, and to show that a reasonably correct analysis is possible nearly always through the use of the simplest methods of algebra and geometry supplemented by good judgment and common sense.

## AGGREGATE SIZE MANUFACTUERED

The activity, or number of pieces required, of the various sizes of an article may be influenced by many factors, but usually it may be assumed to be fairly uniform, at least over a certain limited range. With this as a basis let us refer to Fig. 1 in which the hori-

---

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

zontal scale indicates the sizes needed. Let it be assumed that over the range $AB$ there are requirements for the sizes 1 to 7 as indicated. If there are no limitations imposed by tool costs, cost of stock-keeping, manufacturing set-ups, etc., upon the number of sizes which can be manufactured economically, there is no reason for not building the seven sizes just as they are needed. The sizes actually manufactured can then be represented by the straight line $CD$ drawn at an angle of 45 deg. if the vertical scale indicates the sizes actually built. Practical cases of this kind are rare, but nevertheless they do exist. In most cases, however, because of the expense involved for development, tools, setting-up costs for tools, stock-keeping, and other similar factors, we find it necessary to limit ourselves to a reasonable number of definite standard sizes. The range $AB$ shown in Fig. 1 might be covered, for instance, by three sizes, each of which might be assumed to be a certain percentage larger than the previous size.

In such a case the sizes actually built may be represented by the "step" curve *abcdefg*. It is evident at once that the aggregate size manufactured is in excess of that needed and that such excess is represented by the shaded triangles above the line $CD$. For any economic study it will be of value to know to what this excess amounts for various values of $x$ which represents the ratio of the difference between the two sizes to the smaller size. This can be determined by a very simple calculation from Fig. 2, which reproduces one of the steps shown in Fig. 1. It readily is seen that the ratio of the excess size manufactured to the aggregate size needed is the ratio of the area of the triangle $c\,d\,e$ over the area of the trapezoid *klec*. This is found to be

$$S_e = \frac{x}{2 + x} \qquad (1)$$

In Fig. 4 the upper curve marked $K_1 = 1$ has been derived from this equation and should prove useful for ready reference in economic studies of this kind. At times the activity decreases or increases with the size. Such cases can also be analyzed, but for brevity their treatment here is omitted.

## BASIC AGGREGATE MANUFACTURING COSTS

In actual practise we are interested not merely in sizes, but usually even more so in costs. The latter may be studied by reference to Fig. 3, which shows in curve $FG$ the relation of manufacturing costs to size for the range under consideration. Such a relationship is generally available from previous experience in the manufacture of similar articles or designs. Consider again a range *kl* as covered by one standard size and make an approximation by replacing the range *me* of curve $FG$ by the dotted straight line *ne*; from the figure it is evident at once, that the ratio of the excess cost of the aggregate size manufactured to the cost of the aggregate size needed is the ratio of the area of the triangle *edn* to the trapezoid *klen*. This ratio is found to be

$$R_c = \frac{K_1\,x}{2 + x\,(2 - K_1)} \qquad (2)$$

The excess cost ratio for different values of $K_1$ (defined in Fig. 3) plotted against $x$ as calculated from eq. 2 is shown in Fig. 4. In many practical cases in which other factors subsequently discussed are rather simple, suitable values for $x$ can be readily determined from Fig. 4 by using proper judgment, especially when it is intended merely to choose between two values of $x$ as given by the available preferred number series.

## CONSEQUENTIAL COSTS AS DEPENDING UPON SIZE

A number of cost factors will be influenced by the fact that the aggregate size manufactured and used is larger than needed. First among these are the packing and shipping costs, which will be increased. Fre-

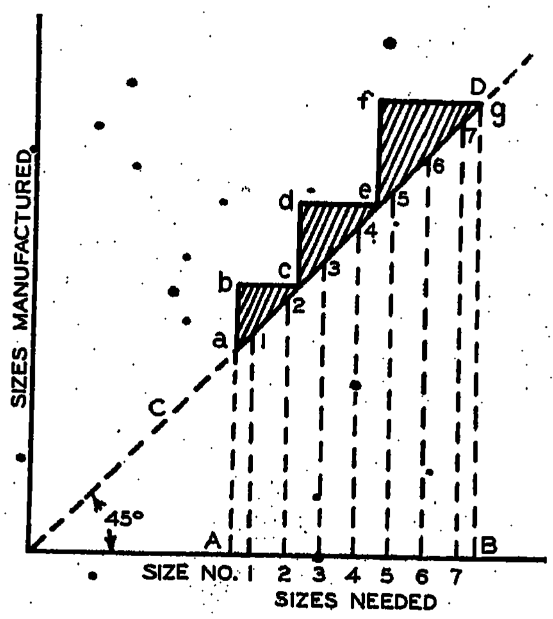

Fig. 1. Diagram illustrating standard sizes

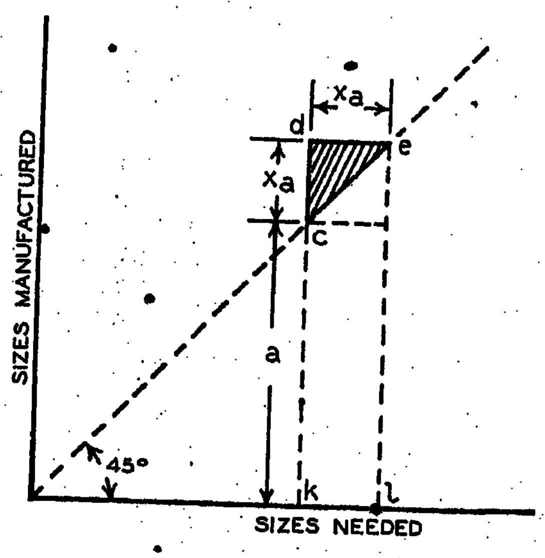

Fig. 2. Excess of manufactured sizes over sizes needed

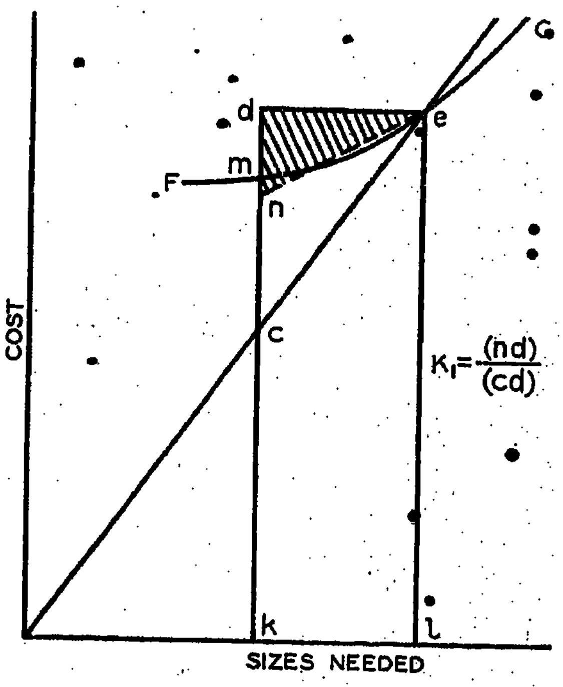

Fig. 3. Excess cost of manufactured sizes over cost of sizes needed

quently the fact that the part manufactured is larger than necessary also results in certain other parts of a design or combination being larger than necessary for the purpose. For example, if a bolt is larger than needed, the stock around this bolt and the cost for drilling and tapping also may have to be increased to some extent; again, if a pedestal bearing is larger than necessary, the bedplate supporting the pedestal will have to be made correspondingly larger. All these factors may be of varying importance even with the same type of article, depending upon the particular application. For this reason an average cost allowance will have to be made for a given range under consideration. These consequential costs will enter into some of the final calculations for the total cost, and can be taken into account simply by adding certain values to the manufacturing costs.

### ENGINEERING DEVELOPMENT AND TOOL COSTS

When a line of articles is developed, there usually are some portions of the cost for tools and development which depend upon the number of sizes manufactured; in other words, the cost of such tools and engineering and development work will be doubled if the number of sizes manufactured is doubled. Assume, then, that in Fig. 5 this part of the development and tool costs is represented by the curve $GH$ in such a way that the ordinates at any one point give the development and tool cost for a size corresponding to such point. Thus the development cost $D$ of the size $le$ would be represented by $lf$. Further, it may be assumed that the total number of pieces to be manufactured during the life of the design over a given range $AB$ of sizes is $N$. If this activity $N$ is uniformly distributed over $AB$ the total number of pieces over the range $ax$ will be

$$N_x = \frac{N}{A\,B}\,a\,x \tag{3}$$

According to previous consideration, the dotted line $he$ may be assumed to be proportional to the sum of the manufacturing costs and the consequential costs of the sizes as needed, so that the ordinate $le = b$ will represent the cost $C$ of the size $le$.

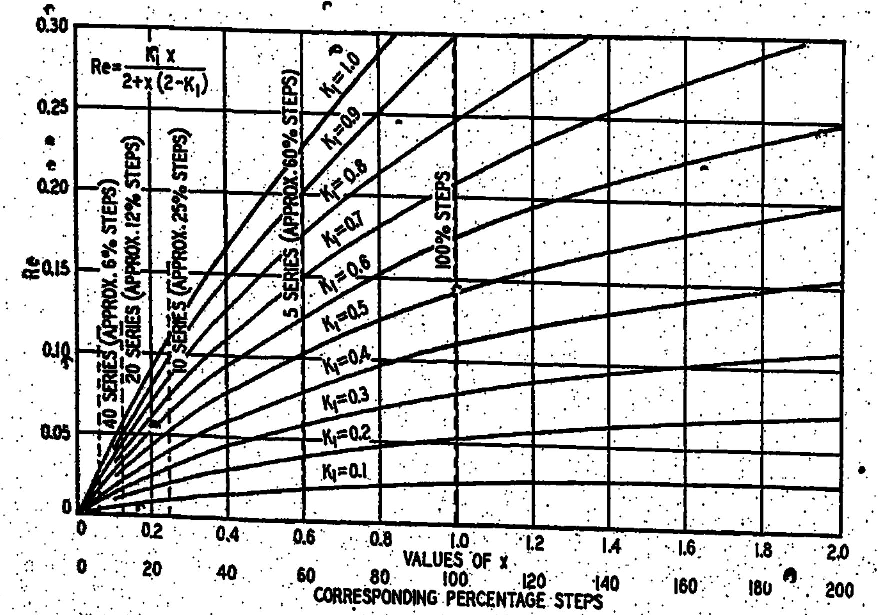

**Fig. 4. Curves showing excess cost of manufactured sizes over basic cost of sizes needed**

The development cost $D$ of size $le$ can be evenly distributed over all the pieces $N_x$ which are manufactured of that size during the life of the design. Therefore, the development cost per piece will be

$$C_d = \frac{D}{N_x} = \frac{D(A\,B)}{N\,a\,x} \tag{4}$$

If $C_d$ in Fig. 5 is entered in the proper scale, the shaded rectangular area may be considered as representing the aggregate development cost for the size $le$.

In addition to the development and tool costs so far considered, there are usually other costs for engineering, development, and tools, which are independent of the number of sizes manufactured. Examples of this are investigations relating to materials or methods, and similar fundamental developments. Another example is certain tool machinery which can and will be used in the manufacture of all sizes. Again, there may be some tools which will have considerable wear and which will have to be replaced repeatedly during the life of the design, so that their total cost will be governed by the total production rather than by the number of sizes. This also holds true when the production is so great that several sets of tools are needed regardless of the number of sizes. The costs of the tools just mentioned may be eliminated from our considerations.

### COSTS FOR MANUFACTURING SET-UPS

The manufacturing costs calculated under the heading "Basic Aggregate Manufacturing Costs" were assumed to be the basic costs and did not include any expense for the setting up of tools prior to actual manufacture. In practise it is usually necessary in changing from the manufacture of one size to another to change certain tools and make different set-ups which frequently involve appreciable expense. It is customary to manufacture at one time a number of pieces equivalent to the average consumption for a number of weeks or months. If such consumption or activity is $N_s$ for the range of sizes $AB$, we find that the activity over the range $ax$ for the same period of time is

$$N_{sx} = \frac{N_s}{A\,B}\,a\,x \tag{5}$$

If the total of set-up costs involved when changing from one size to another is $S$ we find the set-up costs per piece to be

$$C_s = \frac{S}{N_{sx}} = \frac{S}{N_s}\,\frac{A\,B}{a\,x} \tag{6}$$

The previous calculations regarding set-up costs are made under the assumption that there is reasonably great activity for each size and that such sizes are manufactured for stock. There are certain cases of large machinery, however, where practically every machine is manufactured as the order is received; thus a set-up cost is incurred for every order. If the set-up cost is independent of the size, it can be eliminated entirely from our calculations, but if it is dependent upon the size, it may be considered merely as part of the manufacturing cost and treated as such, as outlined under the heading "Basic Aggregate Manufacturing Costs." At times there may be cases between the two extremes just discussed which will necessitate calculations representing a combination of those outlined.

### COST OF STOCK KEEPING

If the articles manufactured are marketed through a great number of small dealers, the total stock they carry and the expense incurred will be greatly influenced by the number of sizes. Assume that the average dealer feels that he has to have one or two pieces of each size, and possibly certain part stock for each size on hand at all times. He then incurs costs for invested capital, storage space, etc., proportional to the number of sizes carried. Similar costs may be incurred also because some of the stock will become obsolete before it can be disposed of, necessitating scrapping or selling at a loss. For calculations here it may be assumed that all of these costs incurred per size are represented by $F$. Assuming further that the activity over the range $AB$ for the life of a given design is $N_f$ the activity over the range $ax$ will be

$$N_{fx} = \frac{N_f}{AB}\, a\, x \qquad (7)$$

This means in turn that the stock-keeping cost to him for each piece is

$$C_f = \frac{F}{N_{fx}} = \frac{F}{N_f}\;\frac{AB}{a\, x} \qquad (8)$$

If the manufacturer keeps only small stocks and the size of his stock is affected by the number of sizes, the same as just discussed for the dealer, the calculations are of course exactly the same. Similarly, the manufacturer's stock in district warehouses may be dependent upon the number of sizes.

In the case of a manufacturer dealing with large quantities, the total stock kept may be practically independent of the number of sizes manufactured. If such is the case, the cost for this stock-keeping may be eliminated from the considerations. This applies also to part stock which is common to all or to several sizes.

### COST OF SPARES AND STOCK IN THE USER'S PLANT

When the user or purchaser of an article finds it necessary to keep a limited stock of each size, the considerations and calculations again are the same as immediately above. The same general principles apply regardless of whether this stock is kept for manufacturing purposes, as spares, or as spare parts for apparatus and machinery operated in the user's plant. One of the principal differences to the user from the costs immediately above may be a rather appreciable cost of spares because (on account of the importance of continuous operation) he may find it necessary to keep a complete spare machine in stock for each size when he has only one or two machines of each size in operation.

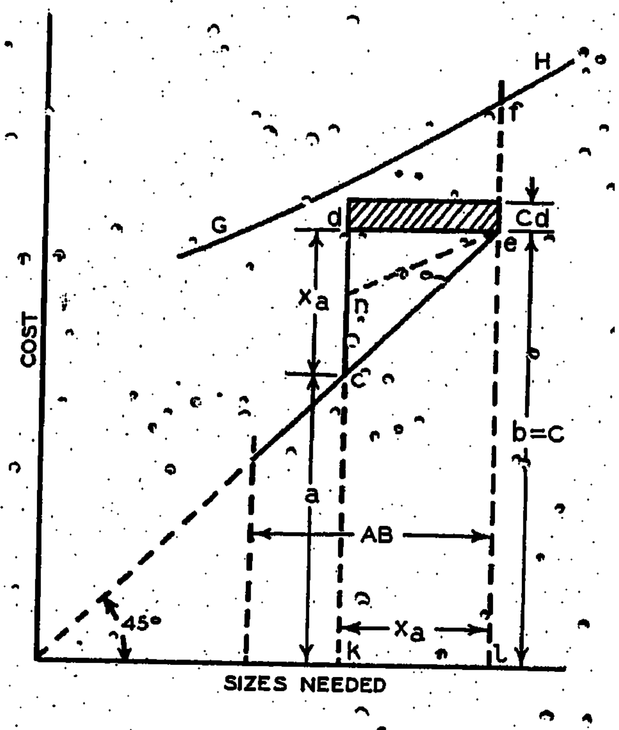

**Fig. 5. Diagram illustrating cost of development and similar costs**

As in previous cases, we can write the following equation

$$C_u = \frac{U}{N_{ux}} = \frac{U}{N_u}\;\frac{AB}{a\, x} \qquad (9)$$

in which $C_u$ is the cost to the user for his stock of spare material, $N_u$ is the activity of the range $AB$, and $N_{ux}$ the activity over the range $ax$.

Certain spare parts common to all or several sizes again may be neglected in this calculation.

### COST OF CLERICAL AND ROUTINE ACTIVITIES

In the manufacture and marketing of most articles there are a great many clerical and routine activities. When an article is first marketed, certain publications and price lists have to be issued. Any part of such expense which is dependent upon the number of sizes may be readily treated as part of the development cost. Certain routine in the works organization, such as the entering of orders, might be considered as part of the set-up cost, while other clerical activities in connection with stock-keeping of course may be combined with the cost of stock-keeping. Then again there may be other routine activities of a different nature which cannot be made a part of any of the costs previously treated, but which in nearly all cases may be taken care of in a very similar manner and by formulas corresponding to those given. Any such clerical or routine activities which are independent of the number of sizes may be omitted from considerations.

### TOTAL FIRST COST

As indicated previously interest is focused chiefly on those costs which are dependent upon the number of sizes. Some of these as indicated by eq. 2 increase with a decreasing number of sizes. While this equation was derived for the basic manufacturing costs, it is equally correct if the cost curve $FG$ in Fig. 3 is assumed to include the costs discussed under the heading "Consequential Costs as Depending on Size" as well as certain costs indicated in the last paragraph under "Costs for Manufacturing Set-Ups." Most of the other costs discussed decrease with decreasing number of sizes.

It is now merely a question of carrying through the development of a formula giving the sum of all costs and finding the ratio $R$ of the total cost to the basic manufacturing cost $C_n$ incurred if each size were manufactured as needed. The value found for $R$ is

$$R = \frac{C_t}{C_n}$$

$$= \left(1 + K_1 \frac{x}{2 + x(2-K_1)}\right) \cdot \left(1 + K_3 \frac{1+x}{x}\right) \qquad (10)$$

where

$$K_3 = \frac{1}{C} \; \frac{AB}{b} \left( \frac{D}{N} + \frac{S}{N_s} + \frac{F}{N_f} \right.$$

$$\left. + \frac{U}{N_u} + \ldots \right) \qquad (11)$$

and

$C$ = the cost previously defined in connection with eqs. 3 and 4, but including where necessary an allowance for costs as discussed in the last paragraph under "Costs for Manufacturing Set-Ups."

We thus have a fairly simple and complete formula from which it is possible to calculate the total first cost for various values of $x$ assuming, of course, that there are at least approximate basic data available from which $K_1$ and $K_3$ can be determined. A typical curve calculated from these formulas is given in Fig. 6. From it can be determined the relation of excess costs over basic manufacturing costs for different steps between sizes.

### UTILITY, SERVICEABILITY, AND PERFORMANCE

Consideration of utility, serviceability, and performance has been left for discussion until now not so much because it is of less importance than the previous items, but because in many cases these three items cannot be made the subject of exact calculation. Their influence therefore often has to be determined by judgment with the aid of such curves as shown in Fig. 6. This will be shown in a number of examples.

Frequently the utility of an article is greatly increased if it completely fills a given space. For example, often it may be desired to use as large a kitchen range as possible within the space available. In view of this it is obvious that a line of ranges inclusive of many sizes will have greater general utility than a similar line composed of fewer sizes. Assume that in a case of this kind the cost curve of Fig. 6 applies, giving a minimum first cost for $x = 0.4$. It is evident at once that on account of the utility feature, the 10 series of preferred numbers, giving 25 per cent steps and corresponding to $x = 0.25$, should be chosen in preference to the 5 series with 60 per cent steps and $x = 0.6$. Even the 20 series, with $x = 0.12$ and an increased first cost of 6 per cent, might be considered. On the other hand, it is more or less evident that since the 40 series would increase the first cost as much as 20 per cent, probably the choice of it would make the manufacturer covering such a large number of sizes non-competitive.

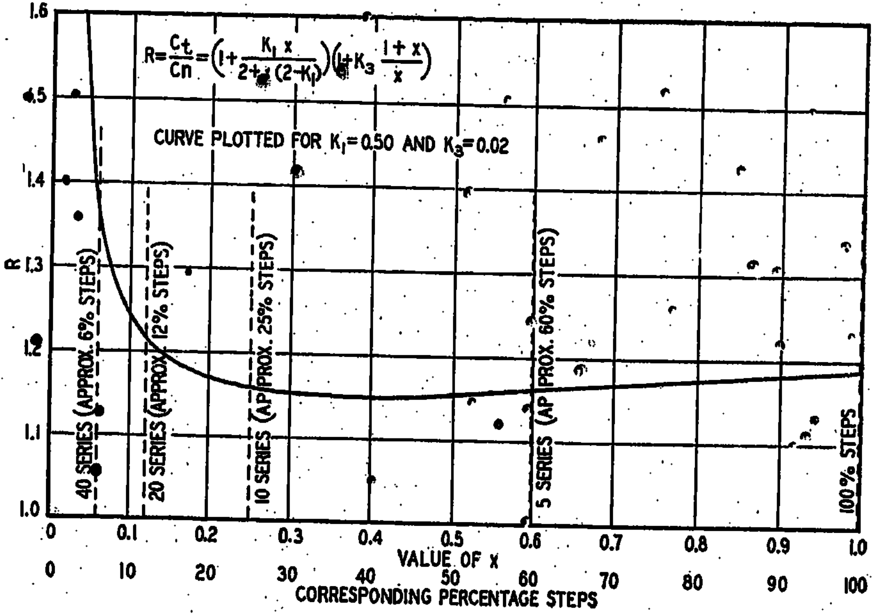

Fig. 6. An example illustrating ratio of total cost to basic cost as related to size of step used

In the case of machinery the question of efficiency or other factors of performance have to be considered. This then may necessitate an engineering study of such factors, and as a result of such study, it may be concluded that the steps considerably smaller than indicated by the curve shown in Fig. 6 should be chosen.

In previous examples the utility and performance considerations tend toward the use of more steps than indicated by the cost curves. An example of the opposite kind would be where the wear and tear of apparatus is of great importance. If but few steps are available, the installed apparatus in many cases will be used below its full rating, which will frequently reduce the average wear. In a case of this kind the use of the 5 series might be resorted to with the cost conditions of Fig. 6, indicating for the 5 series an increased first cost of only 1 per cent over the minimum.

Other instances where the utility favors the use of larger steps are those of machinery where there is a likelihood of the load increasing as time goes on. If in such cases few steps are used and if as a consequence many of the applications are underloaded to begin with, the necessity for installing new and larger machines will be minimized. Another factor which is frequently of importance with regard to the utility of an article is its interchangeability with other similar articles. The possibilities for such interchangeability are better of course with fewer sizes, and therefore with cost conditions as indicated in Fig. 6, this consideration might lead to the choice of the 5 series in preference to the 10 series.

Even when several of the previous factors have to be taken into account, the proper choice of $x$ usually does not present great difficulties after curves as given in Fig. 6 are available.

### MISCELLANEOUS FACTORS

A number of miscellaneous factors may enter into the picture. Assume, for instance, that a new type of apparatus is being developed and that there are uncertainties regarding the design and various commercial factors, all of which may bring about changes in the design sooner than contemplated. If in such a case Fig. 6 indicates the cost condition, it would seem to be good judgment to start with the 5 series, with plans for filling in later on to obtain the 10 series after experience has been acquired.

In actual practise, too few sizes may entail extra expenses which cannot be included readily in the cost calculations as previously given. If, for example, shafts of various sizes are machined from the round stock, the cost of machining many of the shaft sizes will be increased if the number of stock sizes of the raw material is decreased. If Fig. 6 is assumed to apply to a cost study of this kind and the extra cost of machining has not been included in the calculation, it at once is evident that the 20 series is likely to be the best choice. Of course the manufacturer cannot ignore completely his own commercial situation; for example, it is evident that a manufacturer having a greater number of sizes available, is likely to secure a larger proportion of business than one having fewer sizes. This in itself might be a deciding factor in favor of choosing the 20 series in preference to the 5 or 10 series in a case covered by the curve of Fig. 6.

### PREFERRED NUMBERS

In the foregoing, repeated reference has been made to "preferred numbers" and it has been taken for granted in the examples cited that in every case one of the standard series should be chosen. While such curves as shown in Fig. 6 may indicate a minimum for values of $x$, which are different from those corresponding to one of the preferred series, it fortunately is true that near the minimum these curves are rather flat. This means that after considering some of the utility features or similar factors, it nearly always is possible, as indicated by the examples given, to choose one of the standard series to good advantage. There may be exceptional cases where for some reason or other this is not advisable or possible. Thus it may happen that the most economical conditions can be obtained with steps much larger than the 60 per cent steps of the 5 series. For such a case, 100 per cent steps can be readily obtained by using every third step of the 10 series; or 150 per cent steps will result from the use of every second step of the 5 series. In fact, nearly every condition encountered in practise can be taken care of by using some combination of figures chosen from the preferred-number series.

In the space here available it has been impossible to treat all the conditions which may be encountered in the great variety of industrial products; each case will be somewhat different and therefore various methods of attack will have to be used. The principal purpose of this brief outline is to stimulate interest in this important subject of standardizing sizes and ratings. The fundamentals discussed are intended merely to assist in a more rational solution of the problems. If they are judiciously applied, together with an increased adoption of preferred numbers, marked economies to both the consumer and the producer of industrial products undoubtedly will result.

# Cooperative Instruction in Engineering Schools

ALTHOUGH the cooperative method of instruction is assured a permanent place in engineering education, cooperative courses in general still are considered to be in an experimental state of development. In a current A.I.E.E. paper (see footnote) by D. C. Jackson, Jr. (F'30) of the University of Kansas, some well known factors controlling the establishment of this plan of education are reviewed as are some of the general methods of applying it to various types of institutions.

While the author states that "no exact conclusions can be drawn concerning the general principles governing the installation of the cooperative method," he expresses the belief that it is not *universally* applicable to engineering schools and polytechnic institutes; nor is there any one *best* method of using it.

---

Abstracted from "Application of the Cooperative Method of Instruction to Engineering Schools and Polytechnic Institutes" (No. 31-113) by D. C. Jackson, Jr., presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1931.

# Steam vs. Electricity for Driving Power Station Auxiliaries

During the past few years important changes effected in power station and system design have reduced operating expenses materially. At present, however, station designers are giving more attention to the reducing of investment costs. This reduction of plant investment quite naturally affects the plant auxiliaries as well as other station equipment. Many large stations built recently have practically all of the essential as well as the non-essential auxiliaries driven by electricity; but in other recent stations steam driven auxiliaries have been used quite extensively. In the light of present conditions and past operating experience, therefore, the A.I.E.E. power generation committee felt that a review of the characteristics and merits of both steam and electric drives would be in order. Accordingly, this committee has sponsored three papers to be presented at the Institute's forthcoming winter convention, and upon these papers the following three articles are based.

## I—Importance of Reliable Auxiliaries

By
F. H. HOLLISTER
Member A.I.E.E.
Sargent & Lundy, Inc., Chicago, Ill.

A WELL DESERVED reputation for continuity of service is enjoyed by the electric service industry as a whole. The public has become accustomed to receiving continuous service; furthermore, the large investments of the power station companies and of their industrial customers demand an uninterrupted supply of energy. One of the most important factors vitally affecting continuity of power service is the reliability of generating station auxiliary equipment. Reliability therefore well deserves all the careful attention that has been devoted to it in these articles.

The valuation of variable speed auxiliaries makes an interesting study in the application of auxiliary drive. In the past, station designers have used variable speed drives for fans, pulverizer mills, boiler feed pumps, and circulating pumps quite extensively. However, recent developments in the manufacture of auxiliary equipment and station design have made variable speeds less necessary, the one exception to this trend being boiler feed pumps for high pressure boilers. The article on steam driven auxiliaries (Dryer) brings out very clearly the advantages of the steam turbine as a simple and efficient means for obtaining variable speed drive.

Another important point brought out in these articles is that the type of drive best suited to essential auxiliaries such as fans, boiler feed pumps, and circulating pumps, is related closely to, and dependent upon, the general design of the station. Station design in turn is influenced by the relation of the station to the balance of the power system with respect to interconnections, size, and location. For instance, a power station that forms the chief source of supply for an area, and that does not have reliable interconnections with other power systems, quite apparently warrants more reserve equipment and must have a greater number of steam driven auxiliaries for starting up purposes than a station forming a part of an interconnected system. Furthermore, a new power station forming a part of a large interconnected group may be designed and built to operate at a better load factor than a comparatively isolated station thereby reducing the need for variable speed auxiliary drives.

Selection of an auxiliary drive is affected also by the kind of fuel and fuel burning equipment used, as well as by station space limitations. Gas- and oil-fired boilers as well as those burning pulverized fuel are somewhat more flexible than stoker fired boilers and therefore can be taken out of service more readily with changes in load. This favors the use of constant speed electric drive. On the other hand, where the bin system of pulverized fuel supply is used, exhaust steam usually is required to dry out the coal, thus justifying the use of some steam driven auxiliaries. In addition, if ground

---

Based upon "Auxiliary Drive for Steam Power Stations" (No. 32-46) to be presented at the A.I.E.E. winter convention, New York, Jan. 25-29, 1932.

and building costs are high and variable speed is required, the use of steam driven auxiliaries may result in an appreciable saving.

It is interesting to note that the total auxiliary power used by a modern station is a relatively small part of the gross generated power, being approximately from 4.5 to 6 per cent; hence a radical saving in auxiliary power cannot be expected from any type of drive. Likewise, the investment cost in auxiliary power including drive and control equipments is a relatively small part of the total station cost, being in the case cited for electric drive (Smith) approximately 7 per cent of the total station cost. Apparently station designers are more or less free to use either type of drive without seriously affecting either the cost or the efficiency of a power station as a whole. Electric drive is favored for essential auxiliaries from the standpoint of convenience and cleanliness in operation, and also because it is more readily adapted to automatic and remote control, particularly in the boiler room.

As regards maintenance costs, a comparison between steam and electric drive would be of interest; however, representative figures are difficult to obtain, chiefly because sufficient time has not elapsed since the more modern stations were placed in operation. In addition, during the last few years the advancement in station design has been so rapid that it is difficult to find stations of sufficient similarity to make a fair comparison.

In passing to the other two articles of the group it may be said that the treatment is inherently one of generalities because of the many factors that may enter into the selection of an auxiliary drive. Discussion of the subject matter, however, should be of interest in bringing out points for consideration when determining the type of drive best suited for any specific application.

# II—Steam Driven Plant Auxiliaries

By
**W. POOLE DRYER**
Associate A.I.E.E.

Stone & Webster
Engg. Corp. Boston

RELIABILITY may be set down as the most outstanding requirement of electric power station auxiliaries since, among other things, an uninterrupted supply of power depends upon the ability of the *essential* auxiliaries to function continuously. Thus any arrangements made for guaranteeing the operation of these auxiliaries should be appropriate to the degree of service reliability expected from the station. These arrangements for station auxiliaries involve the furnishing of a reliable supply of energy as well as turbines, motors, and accessory equipment which are free from physical defects and which possess suitable operating characteristics. Considerations secondary to this first requirement of reliability are simplicity, initial cost, maintenance expense, and economy of power.

For greatest reliability, essential auxiliary driving units must be supplied with energy free from disturbances which would interrupt their operation. To the extent that the source of supply is exposed to those disturbances, arrangements must be made to limit the effect of any single disturbance to as few auxiliaries as possible, and to provide a duplicate source immediately available should the primary source fail. Minor disturbances such as slight reductions in steam pressure or voltage are to be expected and provision against them should be included in the design of the drives. The question which naturally arises then is "to what extent is the provision of a duplicate source of supply advisable when the essential auxiliaries are steam driven; and to what extent when motor driven?"

## RELIABILITY OF AUXILIARY STEAM POWER

Disturbances threatening interruption of the auxiliary service may originate either within or without the station. In properly designed and operated stations with turbine driven auxiliaries, no external circumstances can disturb the characteristics of the steam supply to an extent which will prevent the auxiliaries from always having available sufficient driving power of suitable characteristics. If not anticipated and arranged for, one circumstance which could interfere with the ability of the steam power to sustain the proper operation of auxiliaries would be the sudden imposition of an abnormally large electrical load on the station. By overtaxing the evaporating ability of the boilers, the pressure in the steam system might be lowered to the point at which some essential auxiliaries would "lie down." The station then would fail to deliver not only its additional load requirements but also its original load. With this contingency recognized in the modern station, and provided for by holding banked boilers in reserve, by accepting load at a rate appropriate to the steaming ability of the boilers, the operation of steam driven auxiliary equipment remains immune to external disturbances.

Troubles originating within the station and affecting the steam supply to the auxiliaries enough to prevent their operation could be caused only by conditions resulting in an excessive lowering of the steam pressure at the throttles of the auxiliary turbines. Under such conditions, certain types of pulverized fuel mills which require a substantially constant torque regardless of output would stop. This might result in the boilers,

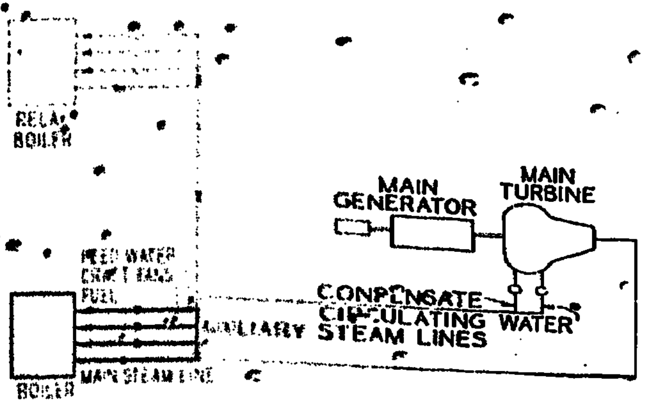

Fig. 1. Energy diagram for a station generator unit with all essential auxiliaries steam driven

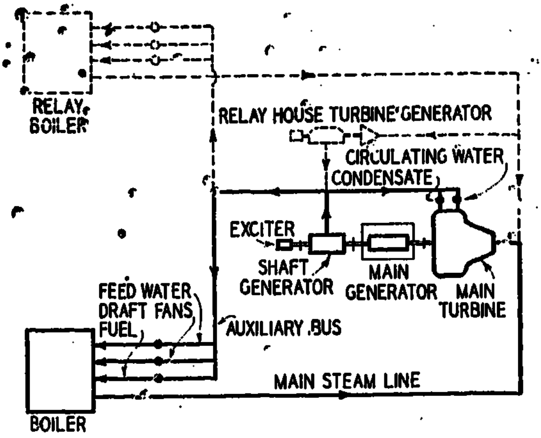

Fig. 2. Energy diagram for station generator with all essential auxiliaries electrically driven

Heavy lines indicate auxiliary equipment and lines which must function continuously to prevent interruptions

being inadequately supplied with fuel, failing to sustain steam pressure. Such excessive decrease of steam pressure, however, is preventable and never encountered in stations properly designed and operated.

### RELIABILITY OF AUXILIARY ELECTRIC POWER

So far as the supply of energy is concerned, a station with electrically driven auxiliaries supplied from a single energy source would not be as reliable as the station with turbine driven auxiliaries. Once the steam energy destined for auxiliaries is transmuted into electrical energy for use in motors, it enters an additional realm wherein its stability is both more sensitive to disturbance and more subject to unexpected attack. Hence, to attain the same degree of reliability as in the station with turbine driven auxiliaries, the station with motor driven units must have duplicate sources of energy.

Since service from the auxiliaries must possess a higher degree of reliability than the main electric power supply, the auxiliaries must be supplied with energy from at least one source not connected to the main generator or to the outgoing lines. This entails furnishing for the auxiliaries at least one generator which may be driven by either the main turbine or by a turbine introduced solely for this special purpose. In important cases, two special generators are used, one driven by each of these turbines. This is done frequently in "downtown" stations of metropolitan systems, where it is considered essential to keep the auxiliary system always free from the effects of external disturbances.

Not only is it necessary to provide special generators and sometimes duplicate distributing systems in stations with motor operated auxiliaries, but it is customary for such important auxiliaries as boiler feed pumps and exciters to rely upon turbines as an ultimate resource.

### RELIABILITY OF TURBINES AND MOTORS

The ultimate reliability of any auxiliary equipment is the compound reliability of its power supply and of the performing abilities inherent in the apparatus itself. Regarding the inherent structural qualities of auxiliary turbines, these machines in their main parts are sturdy, and, as a concession to low initial cost, simple and inefficient compared to the main turbine units. Their parts most questioned are the reduction gears, governors, and valve mechanisms. However, the art of gear-cutting now has been developed so that gears seldom give trouble without ample warning. Governors and valve mechanisms are less certain in operation unless particular skill is applied to their design.

As a basis for evaluating the degree of structural reliability of turbines, they may be compared with the more usual types of motors: the squirrel cage, and the adjustable-speed wound-rotor types. The simplicity of the construction of squirrel cage motors and their accessories probably place them in approximately the same grade of inherent reliability as turbines. Wound rotor motors and their accessories, however, involve parts and constructions which may be preferred only through consideration of power economy. Thus, regarding inherent qualities, it might be said fairly that in the case of constant speed equipment, steam driven auxiliaries are as reliable as those electrically driven; and in the case of variable speed equipment, they are more reliable.

A further aspect of inherent performance reliability in the driving apparatus itself is the relative ability of turbines and motors to drive variable speed equipment smoothly and without transitional disturbances, particularly draft fans. On such duty, the turbine, with its infinite number of speeds, performs evenly. The wound rotor motor, with its step action transition in speeds, is more likely to cause disturbance in burner flames; and further operating complications are encountered in changing from the motor of one speed to that of another.

### RELATIVE EFFICIENCY OF TURBINE AND MOTOR DRIVES

Despite their reliability and simplicity, turbine driven auxiliaries were displaced to a large extent when it was discovered that a fuel saving could be made if steam for producing auxiliary power first was passed through efficient main turbine units to produce electric energy, and then extracted for water heating, instead of being passed through small inefficient turbines driving auxiliaries mechanically and then into feed water heaters. The fundamental reason for this gain in economy is that the surplus energy thus made available is produced much more economically than the rest of the station output energy because the steam required for generating this surplus energy extracted is for heating the boiler feed water. As a result, this steam is utilized at a station thermal efficiency of between 90 and 100 per cent, whereas the steam used for generating the rest of the output energy is carried into the condenser, where most of its original heat energy is lost, and so is used at an efficiency between 20 and 35 per cent.

With regard to the economy actually effected by these changes the examples illustrated in Figs. 3 and 4 show that by substituting motors for turbines on all essential auxiliaries, and by heating the feed water with extracted steam instead of auxiliary exhaust steam a modern station's net output for a given fuel consumption is increased at maximum load about 1.75 per cent; the over-all thermal efficiency of the turbine-driven auxiliary station is 24.4 per cent; for a station with motor drive it would be 24.8 per cent. In this comparison other conditions have been kept similar. It may be observed that in Fig. 3 less steam is needed for water heating than in Fig. 4. This is because the auxiliary turbine in Fig. 3 is inefficient. As a result, hot steam is exhausted, less of which is required for feed water heating than is needed of the cooler steam extracted from the efficient main turbine; however, the greater the percentage of the total steam in the main turbine which can be extracted and used for heating, the smaller the remainder to go into the condenser and the greater the net station output for the same fuel consumption.

Not as a principle unique to either turbine or motor drives, but as one common to both, it should be realized that the station efficiencies shown in Figs. 3 and 4 could and should be increased by heating the feed water further than is shown in these examples by extracting steam from one or two high temperature points of the main turbine. Moreover the 1.75 per cent advantage attained in the station shown in Fig. 4 would have been slightly greater if, instead of using one point of extraction, two had been employed to heat the water to the same temperature; and due alone to the stray losses encountered in actual operation, advantage in favor of electric drive might be as high as 2.5 per cent.

Difference between the efficiencies of the two stations compared would have been very much less if the high efficiencies now obtainable in auxiliary turbines had been assumed instead of the low efficiencies actually taken as better representing common practise. Also, it should be understood that the relative efficiencies of the two stations were estimated for only one station load; with both stations operating at their maximum output, and the auxiliary turbines and motors performing at their maximum loads, and hence at their optimum efficiencies.

## Power Consumption

To ascertain the total difference in power consumption between steam and electric driven auxiliaries over the whole working range of the boilers and turbine generators, and hence the net annual saving in fuel, requires a determination of the power taken at partial loads by both types of drives. This was done by analyzing separately the power input to each essential auxiliary when driven by turbines, squirrel cage, and adjustable-speed wound-rotor motors. In the analyses based upon power output of the boiler, that output was reckoned as the power which the main turbine generator would produce with the quantity and quality of steam delivered by the boiler at its different loads. The power consumed by the turbine driven auxiliaries in all cases was calculated as the power which the quantity of steam used in these auxiliaries would have produced if used instead in the main turbine generators. These analyses represent the performance of equipment in stations having large boilers and turbine generators, where the auxiliary turbines also would be large and slightly more efficient than those often used. However, turbines having higher efficiencies than those assumed in this analysis are now in operation on auxiliary service.

Results of these analyses showed that:

1. For such auxiliaries as circulating water pumps and fuel pulverizing equipment, where the output is substantially constant throughout a wide range of load on the main units, and for which constant speed squirrel cage motors are suitable, the electric drive maintains throughout the entire load range its relative efficiency over the turbine drive.

2. For auxiliaries such as boiler feed pumps and draft fans, in which the output varies with the load on the main units, the squirrel cage motor rapidly loses advantage in the power saving which electric drive gives at maximum load; below approximately 85 per cent load on the main units it is less efficient than the turbine. At lower loads, the initial relationship between the two drives can be reestablished by transferring the load to a lower speed motor, but upon reducing the load still further, this motor will in turn become less efficient than the single turbine.

3. The superior economy which the adjustable-speed wound-rotor motor gives at maximum load over turbine drive diminishes greatly as the load decreases and vanishes at small loads unless operation is transferred to an additional lower speed motor.

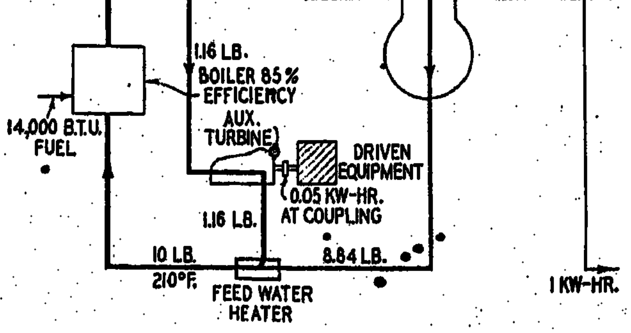

**Fig. 3.** Station efficiency diagram with all auxiliaries steam driven

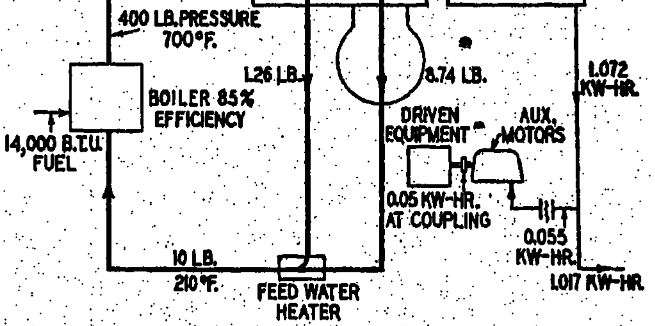

**Fig. 4.** Station efficiency diagram with all auxiliaries electrically driven

## RELATIVE OPERATING COSTS

Conclusions just outlined indicate that from considerations of power consumption, the most favorable application for turbine drive is on equipment like draft fans which, having to traverse a wide range of speed and load, use more than one motor when electrically driven. Even on this application the electric drive saves power; but it involves a larger investment in both driving and generating equipment. Regarding the investment in driving equipment, it is estimated that for large boilers having a maximum output of the order of 500,000 lb. of steam per hour, and with two wound rotor motors per fan, the installed cost of motors, controllers, and wiring for both forced and induced draft fans would be about $10 per rated fan horsepower more than for turbines with their valves and piping.

Regarding the investment in generating equipment assessable against the fan drives, if the fans are electrically driven, and all equipment usually provided for normal and emergency supply assessed, the turbine room cost will be found to increase about $49 per installed fan horsepower. If the draft fans are steam driven, 0.7 per cent more total evaporating capacity is needed than if motor driven; as a result the boiler room in this case costs about $12 more per installed horsepower than in the other case. Those investment costs are based on a total station cost of $95 per kw. output.

On the basis of the foregoing, the total investment incident to the electric drive for fans will be $37 higher per installed fan horsepower than for the turbine drive. If the annual charges on this higher investment is less than the cost of fuel per installed horsepower saved by the electric drive, then motors would be more economical than turbines, and *vice versa.* Seldom, however, would motors be more economical. Even with coal at $4 per ton and a capacity use factor of 100 per cent, the combined fuel cost and fixed charges would be less for the turbine drive than for the motor drive. In plants designed to deliver large quantities of steam for industrial uses or for heating, the economic balance is usually in favor of turbine drive regardless of load factor and fuel cost.

## FUTURE DEVELOPMENTS

To realize fully the advantages obtainable by using auxiliary turbines in conjunction with large main units, more efficient designs and methods of application become desirable, practicable, and commercially feasible. With the conventional designs and applications of these machines, more stages and larger diameters can be used to raise the efficiency at maximum load; however, care must be taken that the gain is not so obtained at the expense of inefficient partial-load operation.

Novel means for securing high efficiency have been adopted in turbines recently installed in one particular large central station; there, not only high rotative speeds and many stages of highly refined design have been introduced, but the steam is passed in series through two turbines. For stations of high steam pressure (600 lb. per sq. in. and more), still other means may be evoked to improve the efficiency of auxiliary turbine operation, as indicated in Fig. 5. Here the improvement is derived through using machines of conventional design, but with novel steam connections. These features contribute to low initial cost of machines and piping, and low maintenance; but much care and some ingenuity of design is required to protect operating continuity while preserving simplicity of design and avoiding undue piping complications.

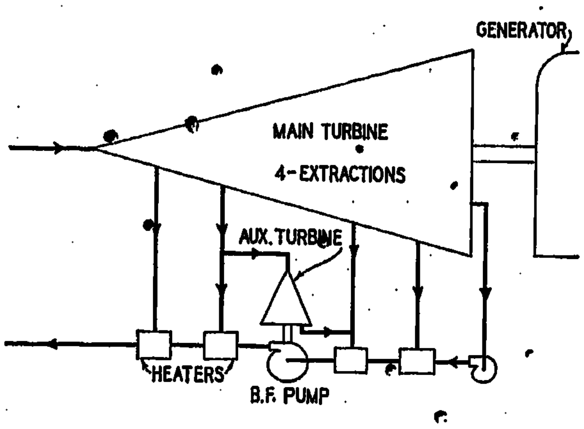

**Fig. 5. Steam and exhaust connections for auxiliary turbines in a typical high pressure station**

In regards to turbine gearing, this accessory usually performs quietly and satisfactorily. It is desirable, however, that still more attention be given to its design and manufacture so as to remove completely the objection to turbine auxiliaries still offered in some quarters where objectional gear noise has been experienced.

While it is indicated that the immediate development of the auxiliary turbine will be along the lines of higher efficiency and greater refinement in mechanical detail, the development of electric drive should be directed toward greater simplicity and lower installation cost. Greater sturdiness of variable speed motors is desirable as is also wider speed ranges; but the greater field for improvement is in distributing systems and control equipment. It is desirable to retain the efficiency and convenience of motor drives without sacrificing reliability, but at substantially lower cost. At the moment just how this end may be accomplished is not clear; but the problem is receiving the attention it deserves, and the great variety of systems adopted in stations built recently indicates that plant designers are far from satisfied with conventional systems and are striving to produce something better.

## CONCLUSIONS

Noteworthy conclusions brought out by the foregoing discussion are summarized briefly in the following paragraphs:

1. At present the turbine constitutes the simplest and most reliable drive for steam power station auxiliaries. For applications requiring extreme protective measures, the simplicity and reliability of turbine drive may warrant its selection for all essential auxiliaries.

2. For maximum load conditions an improvement in over-all fuel economy of the order of 2 per cent will result incidental to the use of motor drive instead of turbine drive for all essential auxiliaries; with both drives; steam would be extracted from the main turbine for feed water heating, more being drawn where motor drive is used.

3. For constant-speed auxiliaries the economy due to motor drive is greater at partial loads than at maximum load.

4. For variable-speed auxiliaries the advantage in economy with motor drive is slight at small loads.

5. Under most conditions the total annual expense for draft fans and perhaps for boiler feed pumps, including fuel costs, maintenance, and capital charges, will be less with turbine drive than with motor drive.

6. There is an element of convenience in the starting and stopping of motor drive which commends it to the average operator, other considerations being approximately equal.

7. The use of turbine drive is not justified for non-essential auxiliaries (which may stop for a short time without inconvenience) these ordinarily being driven at constant speed.

8. Future developments may change the relative status of two drives; but indications are that in the immediate future progress will tend to decrease the advantage in fuel economy which the motor now possesses, and to increase the turbine's advantage of reliability.

# III—Electric Drive for Plant Auxiliaries

By
**L. W. SMITH**
Member A.I.E.E.

Sargent & Lundy, Inc., Chicago, Ill.

A REVIEW of the history of auxiliaries for steam power stations shows a gradual change from complete steam drive to the other extreme of complete electric drive, except for a few reserve steam driven auxiliaries such as boiler feed pumps and service pumps. During an intermediate period, dual steam and electric drive was used quite extensively for some of the essential auxiliaries, but the number of dual drives appears to be diminishing steadily.

Higher efficiency of electrically driven auxiliaries receiving their power from the efficient main turbine or house turbine, as opposed to small inefficient turbine driven auxiliaries, always has been attractive to the station designer. However, lack of confidence in the reliability of the early forms of electric drive for essential auxiliaries retarded its general adoption until more operating experience was obtained and reasons other than greater efficiency appeared.

The change from steam to electric drive is due largely to an increasing feeling of confidence in the reliability of electric drive, an increasing appreciation of the simplicity and flexibility of electric drive, and important changes in boiler and turbine practise. Confidence in electric drive has been strengthened by improvement in the manufacture and application of electrical equipment, the proved value of station and system interconnections, and a record of successful operating experience. The convenience and flexibility of electric drive are known generally, but will be discussed more in detail later. Important changes in boiler and turbine practise that have influenced the use of electric drive are multi-stage bleeding of turbines for feed water heating, the use of higher steam pressures and temperatures, the development of larger boilers and turbines with their multiplicity of similar auxiliaries, and, to some extent, automatic combustion control.

## COMPARATIVE RELIABILITY OF STEAM AND ELECTRIC DRIVE

Reliability always has been considered the chief requirement for essential auxiliaries; steam is considered more reliable than electric drive chiefly because it is a more direct method of obtaining power. Electric drive introduces additional apparatus such as generators, transformers, and switching and control equipment between the boilers and the auxiliary to be driven. If the electric auxiliary is connected directly or indirectly to the main bus, it is exposed also to the effects of line disturbances. Performance of the intermediary equipment required for electric drive now will be considered from the viewpoint of reliability.

Main and house turbines probably are more reliable than efficient auxiliary turbines; furthermore, the larger units receive much closer attention than could be given economically to auxiliary turbines. Concerning the generators, statistics show that failures are extremely rare, especially since closed ventilation systems have been used; but in case failure of the main generator should occur, there is usually no immediate need for the auxiliaries associated with either the generator or the boilers. Auxiliary transformers have an equally good record for freedom from trouble. Modern switching and control equipment too in recent years has given but relatively little trouble, especially when selected and installed with the usual liberal safety factors.

A large proportion of the motors used for electric drive is of the squirrel-cage induction type which is unusually sturdy, and which readily permits full voltage starting with its inherent simplicity of control. However, when correctly applied and maintained, other types of motors also have given good service. Furthermore, improvements in insulation and bearings have made motor coil failures rare.

In regard to the reliability of power supply for electric auxiliaries, the extensive use of bus and feeder reactors, and diversity of power feeds, have tended to minimize the effects of line disturbances. The present trend toward faster operation in oil circuit breakers also

---

Based upon "Electrically Driven Auxiliaries for Steam Power Stations" (No. 32-6) to be presented at the A.I.E.E. winter convention, New York, Jan. 25-29, 1932.

will minimize the effects of line disturbances. From these facts it seems apparent therefore that reliable service may be expected from electric drive when applied correctly.

### SIMPLICITY AND FLEXIBILITY OF ELECTRIC DRIVE

It is difficult to conceive of a simpler drive for rotating equipment than the squirrel-cage motor. Perhaps, however, the greatest advantage in simplicity of the electric motor versus the steam turbine lies in the method of control. A motor for instance may be started and stopped in a fraction of a minute simply by pushing the button, whereas the ordinary small auxiliary turbine usually requires a preliminary warming up. Besides these advantages the convenient control of auxiliaries from a few centralized points, made possible by electric motor drive, often permits a reduction in the station operating staff and contributes toward better efficiency of operation.

Flexibility likewise is an important factor in auxiliary equipment especially from the viewpoint of station design. Here again the almost unlimited flexibility of electric drive gives it a great advantage over steam, as evidenced by modern boiler combustion control systems. The absence of steam piping to the turbine and boiler room auxiliaries, made possible by electric operation results in less congested basements and thereby facilitates station design, operation, and maintenance. Furthermore, in obtaining the station heat balance electric drive provides greater flexibility than steam.

### MODERN TRENDS IN STATION DESIGN FAVOR ELECTRIC DRIVE

Selection of the type of drive for a station's auxiliaries usually is not made entirely on the basis of the relative performance of motors and turbines, but is determined to a large extent by the general design of the station. One of the most important changes in station design and one which has tended to increase the use of electrically driven auxiliaries, is the general adoption of the multistage bleeding cycle for boiler feed water heating. Although complete motor drive for auxiliaries is not required where the stage bleeding cycle is used, electric drive for all auxiliaries in such stations will (1) decrease the B.t.u. per kw-hr. rate of the station approximately 2 per cent; (2) simplify operation by automatically varying with load changes the steam extracted for feed water heating, and (3) simplify the station heat balance system by obviating the transfer of auxiliary load with varying station load.

Another factor favoring the choice of electrically driven auxiliaries is the use of higher steam pressures and temperatures in modern stations. This is because (1) small high pressure auxiliary turbines cost much more than small low pressure turbines, and (2) higher pressure turbines are harder to maintain at their full efficiency and capacity. Operating experience with small turbines indicates that their efficiency falls off rapidly (sometimes as much as 50 per cent) unless they are carefully maintained. This diminishing of efficiency is due to an accumulation of scale in the steam passage; the effect obviously is more pronounced in high pressure turbines because of the smaller clearances.

The trend toward larger stations, which also involves of course larger boilers and turbines, is still another factor in favor of electric drive. These larger units permit the economical use of two or more similar auxiliaries per unit which allows for diversity in the auxiliary power supply and thus increases the reliability of electric drive. Furthermore, a more reliable unit system for auxiliary power supply is justified in these larger stations wherein all essential auxiliaries for a main generator are supplied directly or indirectly from the generator itself.

### COST CONSIDERATIONS

In addition to the many aspects of the choice of auxiliary drive already discussed, any comparison between the two drives introduces at least one other important factor subject to considerable debate—the cost of an electric auxiliary power supply that can be considered equally as reliable as steam. Naturally, the cost of any power supply system involves first of all the amount of power required to drive the auxiliaries.

**Table I—Power Required for Electrically Driven Auxiliaries in a Modern Large Power Station**

| Subdivision | Per Cent of Total Auxiliary Power |
|---|---|
| Coal preparation | 22.0 |
| Boiler feed pumps | 22.0 |
| Turbine auxiliaries | 22.0 |
| Forced and induced draft fans | 20.0 |
| Heater drain pumps | 3.8 |
| Service pumps | 2.6 |
| Station lighting | 2.4 |
| Coal handling | 1.6 |
| Miscellaneous auxiliary power | 1.5 |
| Ash sluice pumps | 1.0 |
| Air compressor | 0.7 |
| Dust precipitators | 0.4 |
| Total (5.5 per cent of gross generated power) | 100.0 |

For an electrically driven auxiliary system the amount of power required is relatively small and depends to a large extent upon the type of fuel-burning equipment used. For a plant burning pulverized coal, from 5.5 to 6.5 per cent of the total gross power generated is required for the auxiliaries; for one employing stokers, from 4.0 to 5.0 per cent; and for one burning gas or oil, from 3.5 to 4.0 per cent. The station load factor and nature of condensing water supply also affect the amount of auxiliary power, but to a lesser extent.

In Table I is given an approximate subdivision of auxiliary power for a typical modern 650-lb. steam-generating station of approximately 200,000-kw. capacity, entirely equipped with electrically driven auxiliaries and using the unit system of pulverized fuel equipment. A study of this tabulation indicates that at best the possibilities of further saving in the amount of auxiliary power appears to be limited to about 1 or 2 per cent of the gross generated power.

### Table II—Investment Cost of Electric Equipment to Drive Auxiliaries of a Modern Large Station

| Subdivision | Approximate Per Cent of Total Station Cost |
|---|---|
| Prorated share of cost for portion of turbo-generator units used for auxiliary power | 0.8 |
| Auxiliary power distribution system, including transformers | 1.0 |
| Motors | 1.2 |
| Control equipment for motors | 2.0 |
| Cable and conduit for motors and control equipment | 2.0 |
| Total | 7.0 |

Investment in equipment is the next cost item considered. Accordingly, in Table II is given an approximate major subdivision of investment costs for the electrical parts of the auxiliaries for the same typical 200,000-kw. station. This station utilizes for auxiliary power two 4,000-kw. shaft generators, and two 9,000-kva. transformer banks connected to the main bus. The main switching equipment and the 2.3-kv. auxiliary switching equipment are of the vertical-lift metal-clad type; for the 440-volt motors air circuit breakers and magnetic switches are used. The boilers are supplied with full automatic control.

In Table II only the prorated share of the cost of turbo-generator units used for auxiliary power is included, because the boilers and the balance of the station equipment are common to both steam and electrically driven auxiliary systems. No allowance has been made for space occupied by electrical auxiliary equipment because it would be approximately the same for either type of drive; however, the flexibility of electric control equipment enables it to use space that otherwise might be wasted. In this particular case, the main auxiliary transformers and high voltage switching apparatus are installed out of doors.

Items in Table II exhibiting the greatest possibilities for saving are the control equipment and cables for motors. It seems apparent, however, that a radical reduction in the investment cost of the complete station will not result even from major modifications to the electrical part of an auxiliary system, but rather will have to come from a series of small savings. Some of the possibilities of making these small changes are brought out in the discussions which follow.

### Electric Auxiliary Power Supply

A review of station designs with respect to the source of electric power for auxiliaries shows quite a variety of arrangements, all of which are modifications of two fundamental systems; (1) power from main bus, or (2) power from a separate generator. The advantages and disadvantages of the principal modifications of these two fundamental systems are covered completely in the National Electric Light Association *Publication 088*, April 1930, and will not be repeated here.

It is interesting to note a considerable trend back to the original system of supplying auxiliary power from the main bus after passing through a cycle of house turbines and shaft generators. The system of taking auxiliary power from the generator leads ahead of the oil circuit breaker is virtually the same as taking the auxiliary power direct from the main bus, and both are subject to the same criticism of being affected by bus voltage fluctuations unless the station has been designed to minimize them. In many instances, however, operating experiences appear to justify the use of these simpler and more efficient systems in large stations which form part of extensive interconnected networks.

Of the two methods mentioned, that of taking power from transformers connected to the generator leads is the least expensive because it eliminates the need for auxiliary high voltage transformer oil circuit breakers. The disadvantages of this scheme are substantially the same as for an auxiliary shaft generator except that the shaft generator of course is free from main bus voltage disturbances. Both are affected if the turbine overspeeds, but improvements in governors and the increasing use of generator voltage regulators for system stability purposes tend to minimize troubles of this sort.

If an electric auxiliary system is to be used in an isolated generating station, a more elaborate power supply obviously will be required. This type of station also will necessitate more steam driven reserve auxiliaries for starting-up purposes than now are considered necessary for a station forming part of a large interconnected group.

Although in some stations house turbine-generators have been employed, their economical use appears to be confined to stations using d-c. adjustable-speed motors or where exhaust steam is used for purposes other than for feed water heating. Many engineers feel that a house turbine is justified as a reserve to the other power sources and for starting-up purposes. The type of turbine-generator that can be started up almost instantly from a remote point appears well adapted for this purpose when local conditions justify its use. For all large stations, however, the unit system of supply appears justified, whether it be from house turbines, shaft generators, bus transformers, or transformers on generator leads. As already mentioned, the chief advantages of the unit system are greater reliability and lower interrupting duty on the auxiliary power control equipment.

## ELECTRIC AUXILIARY POWER DISTRIBUTION

Selection of the voltage for an electric auxiliary power distribution system usually is determined by the standard motor voltages available, together with a study of the over-all cost of motors, cable and control equipment. In many of the earlier stations, cable runs were relatively long and the interrupting duty on the control apparatus relatively light, with the result that motors of 50 hp. and more, usually were operated at 2,200 volts. However, with the present trend toward larger stations and consequent greater concentration of auxiliary power, the cost of control equipment has become a large item of the total auxiliary system cost. The 1926 report of the A.I.E.E. power generation committee pointed out this condition and suggested that a study be made of the possibilities of using a 440-volt auxiliary system with carbon air circuit breakers for control. It is interesting to note that a 460-volt system of this type was adopted for the Gould Street station at Baltimore as a result of a thorough study of investment costs and performance of motors and control. This station is designed for four 36,000-kw. units.

In larger stations with units of 50,000 kw. and upwards, two or more auxiliary distribution voltages usually are required; those commonly used are 2,300 and 460 volts, respectively, although in some stations 550 volts is being used in preference to 460 volts. In many instances an appreciable saving can be made in the over-all cost of motors, control equipment, and cable, by extending the size range of the low voltage motors up to 100 hp. or more, and establishing low voltage power distribution groups central to the group of motors fed by the distribution point.

Sometimes a further saving can be made in the auxiliary power switching and control equipment by diversified grouping of duplicate unit auxiliaries. For instance, half of the auxiliaries required for one boiler may be supplied from one bus section, and the other half from another bus section. This not only provides a more reliable power supply, but eliminates the need for double buses, since it is possible usually for maintenance purposes to isolate at least one-half of boiler auxiliaries during off-peak conditions.

## AUXILIARY MOTORS AND CONTROL

If the present high investment cost of auxiliary motors and control apparatus is to be reduced, every auxiliary drive application calling for variable or adjustable speed motors must be investigated and justified by an appreciable saving in over-all costs. In addition to the high investment cost, the use of variable or adjustable speed motors increases maintenance costs and space requirements and to some extent reduces the reliability of the drive.

A review of motor applications for recent large stations indicates a decided trend toward the use of more squirrel-cage and less slip-ring motors. Machinery designers are being attracted by the simplicity of the full voltage starting possibilities of squirrel-cage motors, and in many cases have withdrawn entirely their demands for slip-ring motors merely for smooth starting. Also some of the equipment which formerly required variable speed drive now is being made for constant speed operation with the exception of boiler feed pumps for high pressure boilers. Station designers too apparently are becoming more willing to give up in favor of the reduced investment and maintenance costs made possible through the use of the squirrel-cage motor, any small gains in plant efficiency obtained by variable speed drives.

In regard to motor control apparatus, considerable progress has been made by manufacturers in supplying self-contained motor control groups completely fabricated at the factory. In many cases where the field labor costs are high, a substantial saving can be made by using these factory fabricated groups. An appreciable saving also often can be made in conduit work by using armored cable installed in metal troughs or large pipes indoors, and by using "parkway" cable for outdoor installations. In the middle west during the past few years this method of handling cables has given satisfactory results.

## SUMMARY

The chief advantages of electric drive over steam drive for station auxiliaries are briefly:

1. It facilitates more efficient station design by permitting all of the steam required for feed water heating to be taken from the main turbine by stage bleeding.
2. It may be approximately twice as efficient in terms of B.t.u. per kw-hr. as steam drive depending upon the amount of maintenance received by the auxiliary turbines.
3. It is uniformly efficient, since lack of maintenance does not affect materially the efficiency of electrical equipment, although it may reduce the reliability of the equipment somewhat.
4. It requires less maintenance.
5. It is simpler to operate.
6. It improves the physical design and operation of a station by reducing the amount of auxiliary piping required, particularly in the basement.

Some of the possible methods introduced for reducing the cost of an electrical auxiliary system are:

1. Obtain auxiliary power supply from transformers connected to the main generator leads ahead of the generator oil circuit breakers, and reserve supply from main bus if reliable interconnections are provided with other stations and station bus is protected by reactors or their equivalent.
2. Establish both high and low voltage auxiliary power distribution groups central to location of auxiliaries instead of in electrical bay, to reduce length of cable and conduit runs.
3. Increase the horsepower range of low voltage motors in view of relatively high cost of high voltage control equipment.
4. Diversify feeds to all duplicate auxiliaries where possible, thereby permitting simpler switching layout for adequate maintenance.
5. Use squirrel cage motors and full voltage starting equipment wherever possible even if at the sacrifice of a small percentage in station efficiency.
6. Use factory fabricated control equipment wherever possible.
7. Use armored cables grouped in metal troughs or large pipes for indoor and "parkway" cable for outdoor installations.

# How About the Human Side of It?

**With sympathetic attention and the direction of modern scientific methods toward achieving a solution of existing problems in human relationships, an ideal civilization is foreseen. This is the sixth article in The Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"**

By
ROBERT D. KOHN
President, The American Institute of Architects

THE MATERIAL achievements of engineering and science during the past half-century indeed are an indication of the wonderful possibilities of the trained mind. But that same mind has not distinguished itself by meeting other problems that have grown even more complex in this same period. The benefits that men have received from science are fairly well known. Why try to make a list of them? Such a process appears academic. Is it not likely to lull us into a sleepy sense of repletion, as if the job were well done and, having dined on succulent self-praise, rest were now due? Or worse still, the pride of achievement actually may blind us to the important problem which science has not tackled at all. The present only-too-evident maladjustment (and indeed the misery from which some part of the world always suffers) is in no small measure an indication of a whole series of such vital problems.

It seems that the very real achievements of science and engineering fail of their effect because the human side of the world's problems has been neglected. We have been absorbed in *things*. We have neglected to notice the effect which men absorbed in things have upon other men absorbed in things. We have been proud, for instance, of what engineering has done to annihilate space. Transportation, telegraph, telephone, and the press bring men from the ends of the earth into a new and closer relationship with each other. But we have done practically nothing to develop a technique of human relations to meet the new problems brought about by those closer relationships.

The wonderful qualities of insight and patience, and indeed the genius that has been applied to the material accomplishments of modern times, now must be turned to a much more difficult job. The results of these discoveries must be turned to a more worth-while, a more comprehensive use. Scientists and engineers (and all of the rest of us for that matter) must now concentrate on the study of the relations of man to man, of group to group, and of nation to nation. We must find a way to understand the interrelation and the interdependence upon each other of men within each function of modern life, and the interdependence of function upon function. When these relationships are better understood they will become clarified, and then be more just. And the distribution of the products of modern methods and the benefits thereof (material as well as spiritual) then will be better adjusted, because of necessity that distribution will be based upon a recognition of the essential nature of the contribution that each group makes to the needs of the whole. And a whole world of latent talents will be evoked during this process.

By far the greatest benefits are still to be conferred on the world by the scientific mind and by engineering skill. They will produce in the future still greater inventions. The physical sufferings of mankind will be relieved by further beneficent discoveries of medicine and advances in surgery. But my hope for the future lies in the belief that we are about to shift the direction of our efforts because we have realized that progress lies in another direction. Doubtless the work in study and laboratory should go on, but the leaders of research and the forward-looking men in all the skilled vocations now must turn to a new leadership. It is their duty and their privilege to direct a study of the much more difficult problems in the neglected field of human relations, and these are not problems that can be solved by the few working alone in laboratories. It is a job for the many, out in the open with the whole world as a field of action. There is a new art to be created, superimposed upon material science, and next to which in complexity modern science is simple. An art it will be because it must develop a sensitiveness to the infinite variations, to the differences in values of personalities, and each such perception will have to be interpreted by other personalities.

The painful inefficiency and injustice of our present civilization shows us that this is the great task. Some say that the essence of this task is the basis of all of religion. Others believe that it is the spiritual background on which a new democracy is to be built. Whatever its name, it is a job that we must tackle, for we live in an age of idiotic contrasts. Part of the world is starving with the food bins elsewhere bursting with a surplus of food. The rest of the world is spiritually starving because of a plethora of the thousand-and-one material blessings. I am not interested now in a review of the scientific skill that has produced these things. I want to see it apply itself to working out a new vision of human relations.

# A Brief Review of Contemporary Dielectric Research

SUPPLEMENTING the annual report of the chairman of the committee on electrical insulation, division of engineering and industrial research, National Research Council, which appeared under the title "The Trend in Dielectric Research" on p. 967-70 of the December 1931 issue of ELECTRICAL ENGINEERING, a résumé of technical and scientific papers presented at that committee's fourth annual meeting and conference held recently at Harvard University is presented in the four articles which follow. Each article is based upon the papers presented at one of the four technical sessions of the conference, each session dealing with one particular phase of insulation research.

In the first article F. M. Clark has digested and interpreted the contents of the papers presented at the session sponsored by the subcommittee on chemistry, of which he is chairman. The other three articles contain brief abstracts of papers presented at the remaining three sessions for the preparation of which the coöperation of J. B. Whitehead, chairman of the committee, and R. W. Atkinson of the General Cable Corporation, Perth Amboy, N. J. is acknowledged.

## I—Chemical Research in Insulating Materials

By
**F. M. CLARK**[1]
Associate A.I.E.E.
General Elec. Co.
Pittsfield, Mass.

INSULATING MATERIALS of the type at present being used in electrical design are difficult to interpret from the standpoint of fundamental characteristics and behavior, not only because of their underlying complexities, but also to a large degree because of their lack of purity. As yet satisfactory methods for gaging the chemical purity of such materials have not been developed despite the fact that their electrical properties depend principally upon the presence or absence of electrolytic impurities. Insulation tests in use generally are electrical in nature; nevertheless their exact relationship to the impurities and chemical behavior of the insulation under test is largely a matter of speculation, and based but little upon experimentally determined facts.

A striking example of the effect of impurities on dielectric strength is the fact that reducing the inorganic ash content of insulation by washing results in a marked improvement in its insulation resistance. About 70 per cent of the ash content of cotton consists of water-soluble sodium and potassium salts; by removing these a 50- to 100-fold increase in the insulation resistance is obtained. Of commercial importance is the fact that washings with distilled water give lower insulation resistance than similar washings with ordinary tap water which usually contains salts of calcium and magnesium. Apparently an ionic interchange is brought about between the alkaline earth salts of the wash water and the inorganic materials of the cotton. In calcium sulphate washings, that portion of the sulphate content of the cotton not associated with alkaline salts remains remarkably constant regardless of changes in the calcium content. With magnesium sulphate washings, the sulphate content decreases due to the greater solubility of the magnesium sulphate formed by the ionic interchange.

### MOLECULAR STRUCTURE OF DIELECTRICS

From such data it may be assumed that the electrical properties of commercial dielectrics depend to a large extent upon their physical structure. Conduction is not due to as great an extent to moisture condensed on the outer surface as to the presence of ionizable salts and moisture within the material itself. Studies on rubber and its purification have served to support this view. Of considerable importance therefore is that proper attention be given to the structural arrangements of the dielectric before attempting to build a superstructure of dielectric theory.

---

[1] Based upon the following papers presented under the direction of the subcommittee on chemistry of the committee on electrical insulation, division of industrial research, National Research Council, during the committee's fourth annual meeting at Harvard University, Cambridge, Mass., Nov. 13-14, 1931:

1. Dielectric Constant and Molecular Interaction, by F. G. Keyes, Massachusetts Institute of Technology.
2. The Structure and Electrical Behavior of Insulating Materials, by J. W. Williams, University of Wisconsin.
3. Molecular Structure and Valence, by J. C. Slater, Massachusetts Institute of Technology.
4. The Influence of the Ash Constituents of Cotton on Its Electrical Properties, by A. C. Walker, Bell Telephone Laboratories.

If atoms and molecules are conceived as being made up of positively and negatively charged particles, some structures evidently will be in good electrical balance, in the sense that the center of the electrical effect of the positive and negative charges will coincide perfectly. When placed in an electric field, such complex structures will polarize because the electrical center of the positive and the negative charges will be pulled out of coincidence. This change produces an induced polarity which, if independent of the manner in which the molecule is oriented, would be representative of the simplest dielectric behavior of gases. Peculiarities in the chemical constitution of the molecule, however, may bring about a disposition of atoms such as to give the molecule a permanent electrical moment in addition to an induced moment; in this case the dielectric constant would be expected to be greater. The orientation of fixed dipoles tending toward alinement parallel to the direction of the field would be expected to be interfered with by molecular collision; since such collisions are a function of the temperature, the result at infinite temperature would eliminate the contribution to polarization through the permanent moment. This theory has been remarkably successful and has stimulated an enormous amount of interest in dielectric behavior. Its extension by Debye and others has been made to account for anomalous dispersion at radio frequency and the absorption of energy in solids.

The extension of the molecular dielectric constant theory to highly compressed gases and liquids offers serious difficulties. To date measurements have been obtained at the Massachusetts Institute of Technology for carbon dioxide, ammonia, methane, and hydrogen. The results for carbon dioxide are typical of what may be expected of the dielectric behavior of a non-polar molecule or one having a non-permanent moment. A non-polar gas should possess a polarization independent of temperature; this is true of both carbon dioxide and methane. With carbon dioxide, the polarizability when extended to the region of liquidity under pressure increases only slightly with increased density. With ammonia, however, the increase in polarizability with density is more marked.

Molecular formation is based upon the attraction of constituent atomic electrons, and the valence bond giving atomic union is a resultant of electronic motion. As suggested by Lewis and confirmed by wave mechanics, homopolar bonds result from shared electrons. Electrons are considered to possess a spinning motion, and a chemical bond results from the mutual attraction of oppositely spinning electrons. Most of the electrons in an atom, however, are bound into closed shells with their spins neutralized. Thus only those electrons with unpaired spins can participate in the valence bond. The chemically inert properties of the helium family of elements is so explained. By the same reasoning, oxygen with its two parallel spinning electrons, a condition preventing mutual neutralization or bonding, offers an opportunity for multiple combination or double valence manifestation. The electrons, however, have a definite spatial arrangement and form bonds at particular angular relations to each other. In carbon, this characteristic results in chemical bond along the axes of a regular tetrahedron; in oxygen and in nitrogen, the bonds are respectively at right angles.

## BEHAVIOR OF MOLECULAR GROUPS MUST BE CONSIDERED

In commercial dielectrics, however, attention cannot be confined solely to the structure of individual molecules. To explain electrical conduction and other physical properties, consideration must be given to the behavior of the molecular *groups* which are influenced not only by simple molecular forces but, in addition, by those forces resulting in molecular *aggregation* and the formation of the massive material. Physical studies on cellulose, rubber, and other commonly occurring insulations indicate the presence of primary valence chains rather than aggregate formation by association through secondary valence forces. Primary valence chains are formed by polymerization or condensation reactions; their regular or random arrangement depends upon the number and spatial arrangement of the reacting group present in the elementary molecules. Substances possessing regular arrangements are known to be anisotropic while those having a random arrangement show the same physical characteristics in all directions. In the complicated system of wood, different conductivities are observed in different directions, but probably for a different reason. A number of regularly arranged cellulose macro-molecules are bound together to mi-cells which in turn probably are held together by amorphous cementing materials. The conducting paths in wood are between the mi-cells rather than between the macro-molecules. X-ray diffraction studies have contributed largely to the present study of these substances of high molecular weight.

To account for absorption and energy loss in dielectrics, the presence of free electrons, free and adsorbed ions, and dipoles has been speculated. The ability of dipole molecules to absorb enough energy to attempt to follow the alternation of the applied electrical field has been the subject of considerable discussion. It may well be doubted, however, that the orientation of dipole molecules can explain the energy loss in the molecular aggregates constituting the usual commercial insulation. The macro-molecules may be compared to long fibers, fixed in position and with but little tendency to follow the applied electrical field, even though they contain many polar linkings and groups. It is possible to conceive, however, that polar atoms or groups of atoms in such molecular aggregates may be displaced from their position of equilibrium by an electric field, thus giving rise to an absorption of energy. Because of the nature of the medium, characterized as it is by high inner friction, the motion of these oscillations will be damped strongly. Therefore, a displacement of the group lagging behind the applied electric field will result provided its period is such that the moments of the groups may revert to practically their normal positions between alternations; an absorption of energy then will result. This behavior may constitute a factor which cannot be neglected.

# II—Properties of Materials Probed in Dielectric Research

PROCEEDINGS of the second session of the insulation conference held recently at Harvard University (see footnote) are reviewed here. Like the preceding session under the guidance of the subcommittee on chemistry, this general session was featured by a distinct scientific atmosphere. Several papers were presented dealing with the electrical properties of important types of simple and complex dielectric materials as related to their availability as insulators.

Results of dielectric studies on vulcanized rubber, containing from 2 to 28 per cent sulphur within the temperature range of from 30 to 100 deg. cent. and within the frequency range of 60 to 2,000,000 cycles, were presented by D. W. Kitchin (A'29). More extended data on the well known anomalous dispersion and absorption of rubber sulphur compounds indicated that the theory of dipole orientation frequently evoked in this connection requires some modification. For example, the 600-cycle curve of dielectric constant *versus* percentage of combined sulphur shows no maximum, but rises steadily. Apparently the agents responsible for the anomalous electrical properties are present at any temperature, but their response to the field depends upon the physical state of the material. In tests on samples of high sulphur content, an increase in dielectric constant with temperature was observed. This is attributed to a polarization due to dielectric absorption, caused by particles having a wide range of relaxation times.

A series of studies on the dielectric behavior of solutions of cellulose derivatives in butyl acetate for the frequency range from 1x10$^5$ to 25x10$^5$ cycles was reported by J. B. Miles, Jr. For low cellulose concentration, the power factor and loss were shown to be accounted for completely by conductivity. This did not hold true for the higher concentrations, however, and it is suggested that the additional loss under those conditions is due to dipole orientation. Agreement with Debye's theory is lacking, though, and internal or molecular viscosity is suggested as a possible cause.

In an interesting speculative paper E. J. Murphy extended his proposal of last year, that dielectric absorption, or as he calls it "residual polarization" in certain dielectrics, is due to the presence of internal surfaces upon which ions may be adsorbed. The residual polarization is formed by the redistribution of the ions in an electric field; with increasing field, some of the ions may be separated from the surfaces. This would result in a decreasing dielectric constant and an increasing conductivity with increasing field intensity, the latter effect having been observed frequently. The author supported his theory by the results of some experiments with fine powders; in these tests both types of variation were in evidence.

Further data on the behavior of highly pure hydrocarbon liquids were presented in a paper by L. A. Welo who reported studies on normal decane, dimethyl octane, and on transformer oil. The liquids were studied through a series of successive distillations and cycles especially designed to remove moisture, air, and suspended matter not only from the liquids, but from the measuring system as well. In all cases, low conductivities (of the order of $10^{-18}$ mhos) were reached; the suggestion was made that the conductivities of all hydrocarbons including oils may be reduced to about this value, and that little if any variation of conductivity with structure is to be expected. When the 60-cycle power factors of these purified liquids were measured, losses about $10^6$ times those computed from the conductivity were observed, indicating a large initial absorption or conductivity even in these purified liquids. The obvious explanation for this is that the application of continuous potential difference sweeps out a large number of ions which are active in causing dielectric loss in an alternating field, a picture which is supported by the saturation current-voltage characteristic of the conductivity measurements.

Measurements of irregularities in the conduction current of insulators subjected to constant voltage were reported by F. E. Haworth and R. M. Bozorth. These fluctuations or "noise" were observed by amplification as in the Schrott effect. It is indicated that ions or electrons impinge upon the electrodes in groups of increasing amount depending upon the field strength. The results support the idea that small conducting canals are created in the dielectric at field values considerably below that of breakdown and in increasing number as the breakdown value is approached; sudden discharges traverse the canals, thereby causing the current irregularities. However, the proportion of total current represented by these canal discharges is relatively small.

A paper presented by J. C. Balsbaugh (A'23) and P. H. Moon (M'29) described (1) a precision bridge for measuring the power factor of small oil samples, (2) ac-

curate adjustable air capacitors, and (3) oil cells to be used therewith. Further refinements were reported in electrostatic screening and in the electrical balance between guard ring and measuring electrode, points emphasized in the development of the Johns Hopkins bridges, with the result of a still further increase in the sensitivity available in bridges of the Schering type. Although no tests on the oils were reported, it is indicated that a sensitivity of better than $+$ or $-$ $10^{-6}$ in the value of loss-angle will be available; on account of the better control possible in the use of small samples, this should permit further refinements in such measurements.

# III—Physical Theories of Dielectric Behavior

IN THE session of the Harvard University insulation conference (see footnote) held under the auspices of the subcommittee on physics, a series of five papers bearing on present physical theories of dielectric behavior was presented. In the first of these, W. F. G. Swann drew a series of analogies amongst the accepted mathematical developments of the theories of steady currents in conducting media, electric induction in non-conducting media, and magnetic conduction in magnetic media. Formal expressions for the fundamental phenomena in these three fields are known to be quite similar. It was shown, however, that there are certain aspects imposed by the restriction to constancy of specific resistance, constancy of permeability, and similar factors, and also by the nature of the mathematical solutions, which raise some question as to the complete accuracy of many accepted relationships. Notably, it is shown that in the general case of simultaneous electric and magnetic fields, it is possible to have at a surface of separation between two media, physical conditions which are not consistent with the usual assumptions made in this case.

As is well known, attempts frequently have been made to draw direct analogy between the properties of dielectrics and those of ferromagnetic materials. In discussing this question, H. Müller pointed out that the parallelism between Langevin's theory of paramagnetism and Debye's theory of polar molecules, suggests the possibility of finding insulators with dielectric properties analogous to the magnetic properties of a ferromagnetic substance. He concludes that such insulators may exist if (1) the substance contains a large number of polar molecules and the temperature is below the critical Curie value, and (2) the polar molecules are able to rotate without association. In support of these assumptions, measurements of the Kerr effect in Rochelle salts were reported.

A series of direct measurements of the relaxation time of abietic acid within the temperature range from 10 to 50 deg. cent. were reported by J. B. Whitehead (F'12) with corresponding measurements of dielectric loss. The method of analyzing dielectric losses which permits the separation of components (reported by A. Banos, Jr. later in the same session) was utilized for comparing the experimental behavior of abietic acid with the expressions proposed in the Debye theory of polar molecules, and with those of the Maxwell theory of dielectric absorption. It was shown that within the temperature range mentioned, the relaxation time is not continuous and that if polar molecules are involved, at least two types are present. The results in general, indicate a behavior in resin more in accord with the Maxwell theory of dielectric absorption, with progressive changes in conductivity and in viscosity accounting for the observed changes in dielectric loss. On the other hand, the experimentally observed change in dielectric constant apparently is not accounted for by either theory.

An interesting series of studies on the oxidation of insulating oil was presented by H. H. Race (A'24). A certain commercial oil was separated into nine samples; these were heated in contact with air at different temperatures for different lengths of time under which conditions studies were made of a number of properties such as conductivity, dielectric loss, spreadability on water, acid number, and viscosity. The results on oxidation were discussed from the standpoint of Debye's theory of polar particles, with conclusion that the number of the particles varies rather than their size. Other studies of the correlation of various properties also were given, with the conclusion that the spreadability test in conjunction with the variation with frequency of dielectric loss under oxidation are the most promising methods for studying progressive changes in insulating oils.

Detailed results of an analytical study of the method for utilizing continuous potential charge and discharge currents observed by the amplifier oscillograph for the prediction of dielectric behavior under alternating stress, were reported by A. Banos, Jr. It was shown that if the portions of these oscillograms for an initial time interval corresponding to the period of the alternating cycle be employed, the current variation may be expressed as the sum of three terms, each containing a negative exponential of the time. This expression, when substituted in von Schweidler's equations, permits the computation of dielectric losses which agree almost exactly with actual measurements. The analytical study with accompanying curves and measurements of loss, power factor, and capacitance, show the reliability and accuracy of the method.

Abstracted from papers presented at the third session of the fourth annual conference of the committee on electrical insulation, division of engineering and industrial research, National Research Council, held at Harvard University, Cambridge, Mass., Nov. 13-14, 1931. This session was sponsored by the subcommittee on physics.

# IV—Dielectric Research Presages Cable Improvement

THE FINAL SESSION of the insulation conference held recently at Harvard University (see footnote) was devoted more to the practical engineering application of dielectric materials. Ten papers were presented, all of which are reviewed briefly.

In a paper entitled "The Electrical Properties of Impregnated Cable Paper and of Ionized Gas Films," C. L. Dawes (M'15) presented the results of an extended series of dielectric loss measurements in impregnated paper as related to voltage, frequency, and temperature variation. Both sections of cable and laboratory samples with air layers were studied. Several empirical laws were reported, notably for the change in the type of variation with temperature and for the nature of the loss caused by the presence of "ionization" films. Studies such as this involving as it does investigations into the effects of the characteristics of a dielectric's component parts upon its behavior as a whole, have come about from a recognition of the structural nonhomogeneity of dielectrics and have had an important bearing upon the recent great improvements in commercial products.

The apparent presence of an appreciable power factor (of the order of $10^{-5}$) in the air capacitors such as those used in dielectric loss measurements, was brought out by J. C. Balsbaugh (A'23) and P. H. Moon (M'29); the importance of making allowance for this in a-c. bridge measurements using such capacitors was emphasized. This condition is attributed to gas, either adsorbed in the electrode surfaces or forming layers thereon, a belief supported by changes in power factor which took place when the air pressure within the capacitor was varied. Influence of variations in the electrode material, and of different types of surface layers of the same material also were studied. In the discussion, two speakers, one of whom was from the U.S. Bureau of Standards, reported experiments on this subject; in neither case was evidence of the presence of power factor in capacitors discovered.

Development of the sensitive measuring equipment used in this study of residual losses in air condensers came about as a direct consequence of the improvements in dielectrics which resulted in requests from utility engineers and manufacturers for equipment capable of making adequate measurement as improvements are continued further. The more obvious imperfections of air condensers that have caused some trouble to earlier investigators were fully eliminated; present investigations, requiring as they do the use of a condenser as a primary standard, not only involve precise electrical measurements, but also necessitate a fundamental study of both the condenser and its electric field.

In two papers, J. B. Whitehead (F'12) reported further experiments at Johns Hopkins University on the properties of impregnated paper used in high voltage cables. The first one described how, by measurements with the amplifier oscillograph of the short time d-c. conductivity and absorption of the oil and the paper separately and in combination, it is possible to follow the separate influences of each on the behavior of the final product very much more closely than heretofore. New evidence was presented as to the correlation between the physical characteristics of the oil and the separate components of the total loss in impregnated paper. The method used was an accelerated life study, samples being tested by the application of successively increasing voltages, starting with 400 volts per mil. A highly refined light oil showed a life greatly in excess of most of the other oils studied; second came an oil of naphthene base; thereafter, in a group in which the variations in life were not great, came a number of oils commonly used in cable manufacture. In the discussion of these results, it was indicated that while the electrical characteristics and the life of the light oil were of high order, oils of this type were not suitable for practical use because of their rapid deterioration, both in the process of manufacture and under those conditions pertaining to cable operation which are not present in laboratory studies. Another interesting result was that although the naphthene base oil had relatively long life, its power factor and loss were so high as to render its use in cables prohibitive. The results in general emphasize the fact that while oils of highly desirable characteristics and long life may be obtained, it may be impossible to use them practically, because of the limitations imposed by the handling and operation of cables in long lengths.

The second of these two papers is a part of a series involving a study of the electrical characteristics of condensers made with commercial or semi-commercial materials and prepared under accurate laboratory control of conditions varied according to a prearranged schedule. The resulting data are adding materially to existing comprehensions of dielectric characteristics.

Interesting results on the influence of high oil pressure upon the electrical endurance of cables were reported by J. A. Scott (A'25). Experiments were made both on cables and on sheet paper immersed in oil. By the application of a pressure of 80 lb. per sq. in. above atmosphere, the dielectric strength of the cable was found to be doubled, with a similar though lesser increase observed in the sheet paper experiments. The effect of pressure on the strength of cable insulation containing voids or bubbles has been recognized fully and studied extensively, but the meagerness of earlier data on the subject discussed by the author adds to the importance of his contributions. Full development of

---

**Abstracted from papers presented at the fourth session of the fourth annual conference of the committee on electrical insulation, division of engineering and industrial research, National Research Council, held at Harvard University, Cambridge, Mass., Nov. 13-14, 1931.**

the laws governing the effect of pressure on dielectric properties is important both from the standpoint of dielectric theory and from that of practical application.

A discussion of the voltage-time characteristics of saturated paper insulation next was presented by R. W. Atkinson (F'28) accompanied by new data based upon extensive experiments on the breakdown life of cable samples under impulse and accelerated voltage step experiments. The results show clearly the limitation of the commonly-used straight hyperbolic voltage-time relation, and the wide error which may result. The experiments reported indicate that within the range of from 5 min. to 500 hr., the voltage-time relation is more closely represented by a formula in which the breakdown gradient is made up of two terms: (1) a constant term representing the voltage which the insulation will stand for indefinite time, and (2) another term inversely proportional to a root of time varying from 1.5 to 4. Especially interesting were the studies of breakdown under impulse voltages, these indicating values very much less than those computed from the law just stated. Indications are clear therefore that formulas of this type are suitable only for studies on the same type of material and within a range of time in which they are known to be applicable. The obvious suggestion is that the impulse breakdowns are perhaps of straight electrical character, whereas the breakdowns under sustained voltage involve other factors such as perhaps local liberation of internal heat. Other data indicate that high-density papers have higher dielectric strength than lower-density papers within the time range mentioned. Another striking fact is that great variation in the shape and slope of the voltage-time curves are found with different types of impregnating material; thus the curves for different compounds may cross not only once but even twice. These data help to indicate the inaccuracy of comparing the qualities of dielectrics without taking into account these variations in the shape of the voltage-time curves.

An extensive series of studies of high voltage cables under operating conditions, involving daily measurements of power factor, loss, and ionization through temperature cycles and at excessive voltages, was reported by R. J. Wiseman (F'27). A feature of this paper was the description of the laboratory arrangement and testing equipment which provided for testing cables carrying heavy current while under voltage stress. The cable ends were sealed and internal oil pressures were measured as were the dielectric losses and the duration of cable life. Based upon an illuminating continuous record of the experiments, the author discussed various factors bearing on cable behavior and the importance of improvement in methods of studying and controlling these factors. Significant data also were given as to bursting stresses to which the lead sheath was subjected by the load cycles imposed.

The deterioration of oils under a-c. corona discharge next was discussed by K. S. Wyatt, in continuation of his work on the deterioration of and wax formation in oils such as used for the impregnation of paper. In the experiments the oil was subjected to corona discharge, the gases formed thereby forcing the oil into a power factor measuring chamber. From the latter, the oil due to its own weight flowed back into the original discharge chamber, thus permitting a circulating action and continuous observation. The results showed a marked increase in the dielectric loss with duration of corona exposure. In the case of a water-white paraffin-base oil, in thirteen hours the power factor increased from 0.4 to 4.1 per cent. The exact nature of the increased loss is under further investigation.

The occurrence of ultraviolet light and X-radiation from gaseous discharges within the body of insulation were topics discussed by E. B. Baker and R. F. James. These types of radiation are thought to be caused by electrons and ions falling through high local stresses before collision with the matter. Experiments were reported showing that the production of such radiation usually is associated with unequal potential distribution in the dielectric, a condition often noted. Importance of the question lies in the possible deterioration of the dielectric structure by the ultraviolet and X-radiation.

Further results of the continuous study of cable performance and quality were outlined by D. W. Roper (F'14) these being carried out on the cable systems and in the laboratories of the Commonwealth Edison Co. (Chicago) and correlated with factory tests. The records of nearly 300 miles of 66-kv. cable and a large amount of 33-kv. three-conductor cable over a number of years are reviewed and a number of important deductions made. Two accelerated life or aging tests are discussed. One of these, involving a test voltage of about twice operating voltage and with cycles of heating and cooling, is much more discriminating and valuable than a test at high voltage and without heating cycles. It gives results consistent with practical cable operation; this correlation with extensive operating experience is suggested as establishing the test as an adequate method of proving the satisfactoriness of any given type of cable to meet standard operating conditions. While the establishment of such a test and its relation to operating performance is an important adjunct to effective future developments, it emphasizes the necessity for the development of a laboratory test to predetermine the stability of an impregnating compound under service conditions, and for a factory test adequate to eliminate sections of cable having local imperfections.

Cables performing perfectly under normally heavy loads were shown to have been those saturated with a tacky impregnating compound which in two cases consisted of a mineral oil and in the other two, compounds containing rosin or rosin oil. Presence of rosin or rosin oil, however, does not necessarily mean that a compound will be satisfactory for fully loaded cables; but all cables having a perfect service record with normally heavy loading for long periods, had a low ionization factor. For lightly loaded cables these same qualities seem desirable, but apparently not as necessary.

# Measuring Core Loss at High Densities

**Modern electrical machines employ flux densities in excess of those previously measurable by routine methods. The refined method now available for densities up to 20,000 gausses therefore is recommended for adoption as standard.**

GREATER ECONOMY and efficiency of electrical apparatus require a better knowledge of the core loss values for magnetic sheet steels at high flux densities than heretofore has been available. The Epstein method adopted as standard by the American Society of Testing Materials is at present the routine method of making core loss measurements at normal densities. However, it is inadequate for measurements at densities above $B = 14{,}000$ gausses, and refinements have now been worked out in the new scheme which make it possible to extend the core loss measurements on sheet steel up to $B = 19{,}000$, and on some sheet steel up to $B = 20{,}000$. Although previously a sine wave of applied voltage has been necessary for accurate measurements, the new method does not require the maintenance of a sine wave of induction in order to obtain a true measure of the maximum flux density.

The over-all accuracy of the measurements obtained by this new method approaches the accuracy of 2 to 3 per cent specified for the standard Epstein apparatus and is well within the accuracy of sampling sheet steel. Because of its accuracy, simplicity, and convenience, this method is recommended for use as the standard method in core loss measurements, so that routine acceptance tests may be extended to the high flux densities met in actual practise.

The testing equipment used for obtaining core loss data at high flux densities consists of an alternator of sufficient capacity, an Epstein testing frame, an ammeter, a frequency meter, an r.m.s. voltmeter, a flux voltmeter, and an astatic reflecting electrodynamic wattmeter, connected as shown in Fig. 1. All of these instruments except the flux voltmeter and the wattmeter are included in the present routine test equipment as described in the A.S.T.M. specifications. The wattmeter, while not a portable instrument, is commonly used in laboratory testing. The flux voltmeter consists essentially of a rectifier and a d-c. voltmeter of the D'Arsonval type, so that the indications are directly proportional to the maximum flux density in the test specimen regardless of the wave shape of the induced voltage.

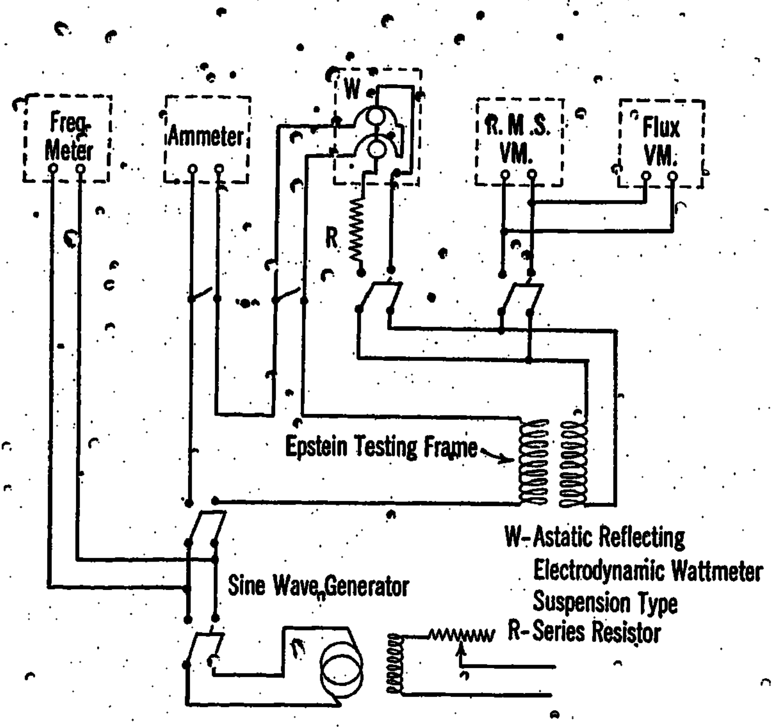

**Fig. 1. Connection diagram of method for core loss testing at high flux densities**

The method previously in use requires that a harmonically varying induction be set up in the test sample by the application of a voltage of sine wave form across the magnetizing coil of the test frame. This method cannot be applied accurately to high density work. The chief difficulty is the large magnetizing force which causes (1) a distortion of the flux wave, (2) a large flux in the test coil and (3) a low power factor.

### DISTORTION OF THE FLUX WAVE

The distortion of the flux wave operates as a source of error in two ways: First, if the maximum flux density $B_m$ is determined by an r.m.s. voltmeter in the secondary circuit according to the well known formula, based on a sine wave voltage, the result will be erroneous. Secondly, it introduces additional losses in the specimen due to high frequency components of the eddy currents. The theory of the method of determining the maximum flux density regardless of its wave shape is based on the following:

1. The maximum alternating flux density is proportional to the arithmetic average value of the induced voltage regardless of the wave form of the voltage.

2. If an alternating voltage rectified without changing the wave shape is impressed on a d-c. voltmeter of the D'Arsonval type, the instrument indications are proportional to the arithmetic average value of the rectified wave which is the same as the arithmetic average of each half cycle of the unrectified a-c. wave.

Measuring the average voltage (*i. e.*, the arithmetic mean value of a half cycle of the voltage wave, corre-

---

Based upon "Core Loss Measurements at High Flux Densities" (No. 31-77) presented at the A.I.E.E. North Eastern District meeting, Rochester, N. Y., April 29-May 2, 1931.

sponding to the point of extreme variation of flux in the associated flux wave) instead of the r.m.s. voltage eliminates the previously mentioned error in the measurement of $B_m$ and makes it possible to determine the true maximum value of the flux irrespective of the distortion.

It should be noted that when $B_m$ is correctly determined, the hysteresis component of the core loss also is correct, the error in the measurement being entirely in the eddy current loss. Since the total eddy current loss is in general a much smaller quantity than the hysteresis loss, it is obvious that the correction to the eddy current loss is a correspondingly small percentage of the total loss. The error in the measured loss cannot be eliminated but can be corrected readily by any one of a number of methods. The simplest and most rapid of these is the per cent eddy method, as it requires fewer test data and calculations. The accuracy is well within the limit of measurements and the method therefore especially is recommended for routine testing. In this method, the percentage of eddy current loss for a sine wave of induction is assumed based on data obtained on similar material. The sine wave core loss is calculated by the relation

$$\text{Sine-wave } W/\text{lb.} = \frac{W/\text{lb} \times 100}{h + k\,e}$$

where

$e$ = assumed per cent eddy current loss
$h$ = 100 − $e$ or per cent hysteresis
$k$ = ratio $\left(\frac{E_{r.m.s.}}{E}\right)^2$
$E_{r.m.s.}$ = the r.m.s. value of the induced voltage
$E$ = the average value of the induced voltage

The form factor $k$ can be computed from simultaneous readings of the r.m.s. voltmeter and the flux voltmeter.

The area enclosed by the potential coil of the Epstein test frame necessarily is larger than the sample area. This necessitates a correction for voltage induced by the air flux. At low magnetization values this is negligible, but at high flux densities when the magnetizing force required is large, the correction is appreciable and must be applied as described below.

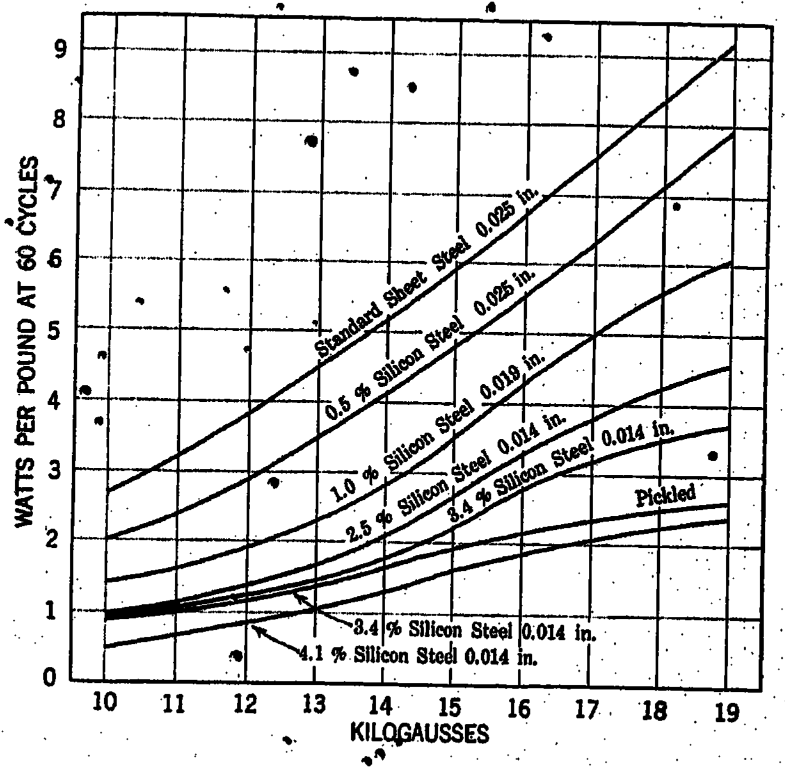

Fig. 2. Core losses of magnetic sheet steels

The total voltage induced in the potential coil is given by the formula

$$E = E_i + E_a$$

where

$E$ = the r.m.s. value of voltage required
$E_i$ = the voltage induced by the flux in the core
$E_a$ = the voltage induced by the flux in the air space

$E_a$ is called the space factor correction voltage. This often amounts to 4 per cent of total voltage at the highest $H$ values, and if ignored would produce a corresponding percentage error in the flux density. Since the voltage $E$ to be maintained always is computed on a sine-wave basis regardless of the form of the induced voltage wave, we have

$$E_i = 4.44\,B\,N\,A\,F\,10^{-8}$$

$$E_a = 4.44\,H\,N\,(a - A)\,F\,10^{-8}, \text{ whence}$$

$$E = 4.44\,N\,F\,10^{-8}\,(B\,A + H\,(a - A))$$

in which

$B$ = maximum flux density in the iron
$N$ = potential coil turns
$A$ = area of test sample in sq. cm.
$F$ = test frequency in cycles per sec.
$a$ = area enclosed by potential coil in sq. cm.
$H$ = air flux in gausses. This is equivalent to the magnetizing force in gilberts per cm. For the purpose of computation, the value of $H$ is usually taken from a d-c. magnetization curve of representative material

The low power factor of the circuit emphasizes the small phase angle error inherent in every wattmeter and also requires that an instrument of large current capacity and high sensitivity be used. The desired characteristics are obtained by the use of a suspension type astatic reflecting electrodynamic wattmeter. This instrument by its high sensitivity permits the use of a current coil of few turns of heavy cross-section conductor. It also permits a potential coil of few turns; that is, a very small inductance and a comparatively large resistance.

At first it was expected that the non-uniformity of the flux distribution over the length of the sample might be a source of considerable difficulty. Tests, however, have shown that the non-uniformity at high flux densities is no greater than at the moderate densities for which the Epstein apparatus was designed; therefore it was assumed that for the present error from this source could be ignored.

The test procedure is essentially the same as that for testing at normal densities. A 10-kg. sample of 50 x 3 cm. strips is made into four bundles and inserted in the test solenoids with paper separators at the joints as described in the A.S.T.M. specifications. The steps are then carried out as previously described.

Some illustrative core loss curves obtained by the routine method are given in Fig. 2. The characteristics of these curves at high flux densities when compared to those at normal densities show the value of these measurements; the reversal of the silicon steel curves confirms what was theoretically expected but seldom shown. It is interesting also to note the effect of scale on the losses at high flux density as illustrated by the two curves of 3.4 per cent silicon steel; one represents the losses before pickling, and the other, the losses after removing the scale. The benefits of this treatment are shown by the measurements to be obtainable only at high flux densities.

The accuracy of these measurements approximates very closely the accuracy of the Epstein apparatus under the normal test conditions at $B = 10{,}000$. This was demonstrated by tests using both sine and distorted waves at this density. Excellent agreement was found between the sine wave core loss and the corrected losses obtained with distorted waves.

The method described is adaptable to the widely used Epstein equipment, combining all the advantages of simplicity, convenience, expeditiousness, and accuracy of that method. In addition, it may be extended into much higher densities. Therefore it is recommended for use as the standard method for core loss measurements in order that routine acceptance tests may be made at flux densities more nearly equaling the highest working densities of modern machines.

# Residences with Arc Welded Steel Frames

ARC WELDED steel framing for dwelling houses is representative of some of the recent experiments in modern building construction. Many advantages are claimed for the welded type of construction, among them being: rapidity and noiselessness of construction, flexibility of design, rigidity and solidity, low rate of depreciation, and a lower insurance rate resulting from the fireproof construction which this method makes possible. What is more important is the fact that all of these advantages may be realized without any appreciable increase in cost over older methods of construction.

Two methods of construction are indicated in the two illustrations. These do not represent any freak combination of new materials but embody only tried and proved engineering principles and construction methods already being applied to larger and taller buildings. Interior and exterior appearances of the finished houses are no different from those of similar houses built by older methods, but notwithstanding this the possibility for individuality in the design and layout of arc welded frame dwellings is thought to be greater than that allowed by present construction.

The entire framework including all interior partitions, of the house shown in Fig. 1, was made up of standard sized panel frames previously fabricated in the welding shop. As may be noted, duplicate frames were used throughout, these being tied together with spacers to provide standard wall thickness. Two sizes of panels were used: namely, 2 x 9 ft., in wall sections without windows or doors, and 6 x 9 ft. for sections including window or door openings. Gable sections were fabricated in the shop, then trucked to the building site and welded to the framework proper.

A somewhat different type of construction is illustrated in Fig. 2; in this case standard steel shapes delivered to the building site like lumber were used throughout without shop fabrication of any kind. Three workmen erected the 10 tons of steel required in this building with no other tools than squares and the usual arc welding equipment.

# Abstracts

## Of Papers to be Presented at the Winter Convention

INTERPRETIVE abstracts of the majority of papers to be presented at the A.I.E.E. winter convention (January 25-29, 1932) are presented herewith, excepting only those papers published in this issue of ELECTRICAL ENGINEERING and those not available for publication at the closing date of this issue. Abstracts of the remainder of winter convention papers are scheduled for publication in the February issue. Members vitally interested and wishing to obtain immediately pamphlet copies of any available papers are requested to use the order form appearing on p. 70 of this issue. In response to popular demand and within its space limitations ELECTRICAL ENGINEERING subsequently may publish certain of these papers, or technical articles based upon them.

### New High Speed Distance Relay With Impedance-Reactance Characteristic

By
S. L. Goldsborough[1]
W. A. Lewis[2]

THE TWO general types of distance relays for isolation of faulty sections of transmission line are impedance relays, operating upon the impedance of the line between the relay and the fault, and reactance relays, operating upon reactance alone. Each of these types has certain advantages as well as certain disadvantages; it is the purpose of this new relay to combine the principal advantages of both types.

The impedance relay is fundamentally more simple, and can be made to operate at a considerably higher speed. However, the presence of accidental arc resistance at the point of short circuit increases the impedance as viewed from the relay, and makes the fault appear more distant than it really is. On the other hand the reactance relay is affected to a less extent by the presence of arc resistance, but in general requires a more complicated structure which does not lend itself readily to obtaining high speed. Furthermore, additional features are required to prevent the operation of this type of relay under normal load conditions. Difficulty is also experienced in making the auxiliary features operate properly in all cases.

Although a relay of this new design can be made to operate as a pure reactance device, it is believed that more satisfactory operation can be obtained by an intermediate characteristic. This modified characteristic permits a relay to be obtained which combines the mechanical simplicity and inherent possibilities of high speed of operation, so desirable where stability is a factor, and the greater independence of the reactance type relay from the effects of fault resistance on the shorter lines. (A.I.E.E. Paper No. 32M1)

### The Theory of Oil Blast Circuit Breakers

By
D. C. Prince[3]

DIRECT experimental proof of the oil blast theory of arc interruption has been assembled. A circuit breaker has been constructed having oil driven between its electrodes at a measurable velocity, and tests show that a correlation exists between the rate of recovery voltage rise and oil velocity. This correlation corresponds to an oil dielectric strength of 55 kv. per 1/10 in. of oil. To determine whether or not this correlation is accidental, relations between voltage and oil velocity and between current and oil velocity have been studied, but correlation does not appear. Impulse tests also have been made on clean and carbonized oils.

Comparative data are available for various methods of forcing the oil blast between the electrodes. It has been found that at the current zero there is a correlation between voltage recovery rates and chamber pressure. This result is surprising since the relation between pressure and oil flow are complicated by the circuit, of passages, back pressure due to oil head and gases generated by the expelled arc.

The laws which govern all variables involved in the design of oil blast circuit breakers are known with the exception of the amount of energy developed by the arc, and even this factor has been observed empirically. Although considerable refinement of the oil blast theory remains to be done, as a whole it rests upon the secure foundation of comprehensive tests and calculations. (A.I.E.E. Paper No. 32-8)

### The Practical Application of the Oil Blast Principle of Circuit Interruption

By
R. M. Spurck[3]

DEVELOPMENTS in theory, calculation, and test results of circuit interruption by means of the oil blast, have placed new tools in the hands of designers, enabling them to construct apparatus of greater efficiency and consistency of performance than heretofore possible. Various applications of these new methods have been made to circuit breakers of all classes and voltages. Circuit breakers equipped with the oil blast device show consistently short arc lengths and unusually short periods of arc duration, even at high rates of recovery voltage rise and over wide ranges of current. The result of this is that contact burning and oil deterioration are minimized and maintenance is greatly reduced. The rapid arc extinction characteristic of the oil blast design makes it admirably suited to breakers requiring high speed of operation.

In most types of circuit breakers, the method of securing the oil blast is by having an auxiliary gap which opens first and by means of the arc formed generates gas to create pressure within the chamber. As the main gap opens, the pressure generated by the auxiliary gap is forcing oil at high velocity through the main gap and down through the contact rod so that the arc products in the main gap are replaced with solid oil of high insulation value which resists puncture by the recovery voltage and at an early current zero prevents further current flow. In a new circuit breaker of very high operating speed the oil blast is obtained, not by the generation of gas in an auxiliary blast but by a piston acting in a cylinder containing oil. **(A.I.E.E. Paper No. 32-9)**

## Recent Developments in Arc Rupturing Devices

By
R. C. Van Sickle[2]
W. M. Leeds[2]

THE EXTINCTION of an a-c. arc by the deion grid method has been very successfully applied during the past two years to the design of an extensive line of arc rupturing devices for oil circuit breakers of all voltage classes. Refinements have been made in the theory of operation of deion grids and in the construction of several types. Field operation and special tests have given much information regarding these devices.

With the deion grid circuit breakers the arc in oil is drawn through a narrow insulated slot open at one end, and magnetically forced into a series of oil pockets. The gas generated can escape only by passing through the arc stream so that the arc is subjected to a continuous turbulent blast of fresh un-ionized gas. A dielectric strength of perhaps twenty times the arc voltage is established within a very few microseconds, and is further increased as deionization continues with the aid of the gas blast.

Laboratory tests have shown that the replacing of plain or quick-break contacts by deion grids reduces the duration of arcing on a 66-kv. circuit to only from 1/4 to 1/7 of the former arcing time, while the arc energy was only from 5 to 10 per cent of the values associated with the old style of contact. Similar results have been observed with circuit breakers for all other classes of service. These results mean great improvement in system stability, reduction in contact depreciation and oil deterioration, and make possible long periods of service without maintenance to the circuit breakers. **(A.I.E.E. Paper No. 32-10)**

## Extinction of A-C. Arcs in Turbulent Gases

By
T. E. Browne, Jr.[2]

IN CIRCUIT breakers employing arcs submerged in liquids such as oil, carbon tetrachloride, or water, the surrounding liquid surface serves both to restrict the arc space and to furnish a gas blast by rapid decomposition under the influence of the high temperature arc. The fiber tube of the common expulsion fuse acts in a similar manner. In the liquid circuit breakers, various devices are available to increase the interaction between arc and liquid, thus aiding in arc extinction.

The results of recent experiments to obtain conclusive evidence of the actual mechanism of such action reveal the following facts:

1. In general the interrupting ability of an a-c. arc is greatly improved by turbulent motion of the arc gases, in a fast circuit this improvement increasing almost in direct proportion to the gas velocity from which the turbulence results.

2. The interrupting ability of a turbulent a-c. arc depends very largely upon the composition of the arc gases, most gases being decidedly superior to air in this respect.

3. The recovery of dielectric strength following a current zero by an a-c. arc subjected to turbulence takes place in two consecutive phases: the first consisting of a very rapid recovery to a substantial value in a few microseconds, and the second of a very much slower further recovery for a much longer period.

4. At least one practical gas blast circuit interrupter, the expulsion fuse, exhibits a volt-time interruption characteristic which clearly indicates the role of gas turbulence in its operation. **(A.I.E.E. Paper No. 32-11)**

## High Voltage Bridge for Measurements of Cables with Grounded Sheaths

By
C. L. Dawes[4]
A. F. Daniel[4]

PRECISION bridge measurements are now in use for measuring the dielectric properties of cables when the current through the dielectric can be conducted directly from the sheath to the measuring apparatus. As a rule, however, these methods cannot be applied to cable with sheaths in electrical contact with ground. There is one method in which bridge measurements are made of all system losses, with and without the test cable connected in the circuit; the difference gives presumably the power loss in the cable dielectric. This method does not give the cable electrical properties (power, power factor, and capacitance) directly, and special precaution must be taken in connecting the cable.

There has been developed a bridge method which does measure directly, and with a high degree of precision, the values of the electrical properties of the test cable even though the sheath of the latter may be grounded. In this method, a four-arm bridge consisting of a standard air condenser and some condenser or cable other than the test cable is first balanced, with the terminal of the galvanometer at the condenser or cable grounded. This balances all system losses to ground. Then the bridge is rebalanced with the test cable connected in circuit. After this last balance, none of the current through the test cable can flow to ground, but must flow through its appropriate bridge arm. The dielectric measurements and also the cable properties thus are read directly from the bridge balance and do not involve correction for system losses. **(A.I.E.E. Paper No. 32-12)**

## A High Sensitivity Power Factor Bridge

By
W. B. Kouwenhoven[5]
A. Banos, Jr.[5]

AN A-C. BRIDGE of high precision has been developed for power factor measurements in an investigation of the properties of cable compounds and papers and of the characteristics of cables that occur after impregnation. The bridge, a modified form of the Schering bridge, possesses several novel features and advantages. The detecting instrument is a moving coil a-c. galvanometer with field excitation supplied from a phase shifting transformer permitting independent ratio and phase-angle balances. A shielded transformer electrostatically isolates the galvanometer from the bridge circuits. This bridge is completely shielded and guarded.

The analytical theory of the resulting mesh connection has been developed in a general manner so that this mathematical treatment may be applied to any similar network. Complete study has been made of the effects upon the balance relation of various sources of error, such as for example, failure to balance guard circuits properly and the presence of leakage resistance between measuring and guard circuits. Experimental verification of the equations has been produced. Power factors of specimens of cable material have been measured ranging from 0.00007 to 0.16 with a maximum variation of ± 0.000005. (A.I.E.E. Paper No. 32-13)

## Power Factor Measurement by the Capacitance Bridge

By
R. P. Siskind[4]

SEVERAL types of capacitance bridge for the measurement of both capacitance and power factor of dielectric specimens are in use at the present time. Some of these make a direct comparison between the capacitance under test and a standard capacitance. For accurate power factor measurements upon dielectric specimens at low voltages and audio frequencies, however, a substitution method is generally preferred. Two substitution methods which may be referred to as the "direct" and the "parallel" are commonly employed. With each method, a small change in the phase angle of the arm of the bridge circuit in which the substitution is made occurs. The compensation for this change enters directly into the measurements, and the essential differences between bridges in common use is in the manner of making this adjustment.

A recommended type of capacitance bridge has been developed having the following advantages:

1. All operating controls are at ground potential reducing the effects of hand capacitance to a minimum.
2. The bridge is entirely self-contained except for oscillator, amplifier, and telephone receivers.
3. All parts except the high-potential terminal for the lead to the test specimen are shielded totally.
4. All controls are variable continuously.
5. The bridge may be constructed entirely of standard parts, the shielding excepted. (A.I.E.E. Paper No. 32-14)

## The Photoelectric Recorder

By
C. W. LaPierre[6]

THE MOVING parts of electric indicating instruments may be light in construction and of low torque, thus requiring small energy input from the circuit being measured. When it is desired to record these measurements, however, the moving parts are usually heavier in weight and require higher torque than the corresponding parts of indicating instruments.

A photoelectric recorder has been developed combining all the advantages of the direct-acting recorders with those of the most sensitive indicating instruments. This is accomplished by providing a separately excited recording element to do the actual work of making the records. A sensitive indicating instrument controls the position of the recording element, the only link between these two being a combined optical system and photoelectric circuit. As the only equipment placed on the shaft of the basic or indicating element is a galvanometer mirror, this element may be even more sensitive than the usual indicating instruments with pointers. Through a system of mirrors and photoelectric tubes the position of this mirror controls the position of the recording element which readily may possess as much torque and be as heavy and sturdy as desired without affecting the basic element or measured circuit in any way. In general, anything which can be indicated can be recorded continuously by means of the photoelectric recorder. It is self-compensating for all normal changes in supply voltage, lamp illumination, and pliotron and photoelectric tube characteristics, and is of an extremely high accuracy. (A.I.E.E. Paper No. 32-15)

## Interconnection of Primary Lightning Arrester Ground and Grounded Neutral of the Secondary Main

By
C. F. Harding[7]
C. S. Sprague[7]

VARIOUS possible transformer connections and protective devices on standard 60-cycle overhead power and lighting distribution systems having 4,000-volt four-wire primaries and power and lighting secondary mains have been investigated over a period of years. Considerable information was furnished by an experimental line with an insulated artificial cloud charged to potentials up to 150 kv. by means of a surge generator. Among the conclusions reached are the following:

1. Efficient primary protection upon an overhead distribution system affords a considerable degree of protection to secondaries located below the primaries.
2. A well-grounded secondary neutral wire acts in reducing potentials on adjacent wires.
3. With existing transformer design, the insulation of the secondary winding may be considerably over-stressed by surges having steep wave fronts, without excessive stress on the primary insulation. Such secondary stresses may be relieved by improvements in secondary insulation.
4. Low ground resistances, although desirable in other respects, do not reduce necessarily the initial potentials which may be induced upon the system.
5. A non-inductive load in the consumer's premises reduces the potentials at the service entrance 60 to 70 per cent.
6. Tests have shown that the interconnection of primary lightning arrester ground to the grounded neutral of the secondary main effects a considerable reduction in voltages at the transformer and imposes no extra hazard upon the consumer's wiring. (A.I.E.E. Paper No. 32-16)

## Field Studies of the Protection of Distribution Transformers By Lightning Arresters

By
K. B. McEachron[8]
L. Saxon[9]

A COOPERATIVE field study with portable impulse generator and cathode ray oscillograph was made of the lightning protection of transformers connected to a 4.45-mile, 4,600-volt rural distribution circuit. The tests described were made with the pellet arrester. The results show that:

1. Although the arrester discharge voltage is but a fraction of the strength of the transformer, arrester ground resistances may be high enough not to protect the transformer if the usual connection to ground is employed. This results in either blown fuses or winding failure.
2. Interconnection of the primary arrester ground and secondary neutral gives a high degree of protection to the transformer from surges originating on either primary or secondary, regardless of the arrester ground resistance.

---

[6] General Electric Company, Schenectady, N. Y.

[7] Purdue University, Lafayette, Ind.

[8] General Electric Company, Pittsfield, Mass.

[9] Utility Management Corporation, New York, N. Y.

3. With low resistance secondary grounds, such as water pipes, both lightning voltages and power voltages on the consumer's premises will be negligible in value, either with or without the above mentioned interconnection.

4. With interconnection it is believed that the possible hazard between separate grounds which now may exist on the consumer's premises, resulting from high resistance secondary grounds, will be greatly reduced. (A.I.E.E. Paper No. 32-17)

## Protection of Distribution Transformers from Failure Due to Lightning

By
A. M. Opsahl
A. S. Brookes[10]
R. N. Southgate[10]

USUAL methods of connecting arresters for the protection of distribution transformers often are inadequate, resulting in flashover of bushings or windings due to lightning, even though the arrester in itself is capable of protecting the transformer with a large factor of safety. Such flashover may be attributed to the fact that surge current flowing to ground through the ground leads of the arrester gives rise to inductive drop and resistance drop which add to the arrester voltage.

Improved protection of the transformer results from the connection of the arrester ground lead to the secondary circuit. The following methods limit the surge voltage across the bushing approximately to the characteristic crest voltage of the primary arrester, but differ in resulting secondary voltages:

1. Direct connection of a low resistance primary arrester ground to a grounded secondary neutral produces no higher voltages on the customer's service than are experienced when flashover occurs with the present protection schemes.

2. Connection of the primary arrester ground to the secondary neutral through a low voltage arrester gives substantially the same results as with the direct connection.

3. Connection of the primary arrester ground through two low voltage arresters to the secondary outside wires results in increased customer voltage. (A.I.E.E. Paper No. 32-18)

## Studies in Lightning Protection on 4,000-Volt Circuits—III

By
D. W. Roper[11]

FOR A NUMBER of years accurate data regarding the causes of lightning failures on distribution lines in the Chicago district and the effect of various methods of reducing these troubles have been kept. For Chicago conditions it appears possible to reduce the total number of transformer troubles annually caused by lightning to less than one per thousand transformers installed, through the adoption of the suggestions below:

1. Use the four-wire three-phase system of distribution with grounded neutral.

2. Install lightning arresters at locations where transformers are connected to overhead primary mains, using low voltage arresters on the neutral wire and valve type arresters suitable for the "Y" voltage on the phase wires.

3. Use transformers having insulation on the coils and leads that will not deteriorate with age and which will withstand a transient voltage test safely above the voltages to which the transformer will be subjected in service when protected by the arresters.

4. If conditions warrant, install a second ground wire and connect it to a second ground rod.

5. Select newest transformers for installation in districts of low transformer density.

6. Require each customer to ground his neutral wire to a water pipe on his premises.

7. Connect the neutral wire of each section of secondary main to at least two ground rods; and on long mains install ground rod connections at intervals not exceeding 600 ft.

8. Where transformers are connected to primary mains 1,500 ft. or more distant from the next adjacent transformers, install on the pole about 600 ft. from the transformers the same lightning arrester equipment as on the transformer pole.

9. Install lightning arresters on all cable poles.

10. Ground the lead sheaths of all underground primary cables. (A.I.E.E. Paper No. 32-19)

## Investigation of Lightning Protection for Distribution Transformers

By
T. H. Haines[12]
C. A. Corney[12]

A HISTORY is presented in this paper showing the results of lightning arrester protection for distribution transformers in New England, where the normal ground electrode resistance is much higher than in most other parts of this country. The general conclusions indicated by this study may be summarized as follows:

1. Experience has indicated that the application of lightning arresters to line transformers in areas affected by lightning reduces the trouble rate by about 50 per cent.

2. Variation in ground resistance within the values readily obtainable in this territory has slight effect upon the efficiency of the arrester.

3. The value of treating grounds or the installation of multiple grounds in an effort to lower resistance is questionable unless by so doing the resistance can be decreased to a value of approximately 100 ohms or less.

4. Insufficient electrical clearances in the smaller and older transformers are an important source of lightning trouble. Larger bushings, and greater clearances are clearly indicated as a necessary feature of correct transformer design. (A.I.E.E. Paper No. 32-44)

## Distribution System Lightning Studies by Philadelphia Electric Co.

By
H. A. Dambly[13]
H. N. Ekvall[13]
H. S. Phelps[13]

INVESTIGATIONS of lightning troubles have been conducted since 1921 on the distribution system of the Philadelphia Electric Company, to determine the magnitude and nature of trouble in various localities, the effectiveness of lightning arresters under field conditions, and methods for improving service continuity. The conclusions may be summarized as follows:

1. About 5 per cent of the aerial distribution transformers annually experience trouble due to lightning, the small transformers being the more susceptible.

2. Lightning arresters were found to afford little benefit to transformers of 15 kva. and less, and substantial benefit to the larger sizes.

---

[10] Public Service Elec. & Gas Co., Newark, N. J.
[11] Commonwealth Edison Company, Chicago, Ill.
[12] The Edison Elec. Illum. Co. of Boston, Mass.
[13] Philadelphia Elec. Co., Philadelphia, Pa.

3. The obtaining of reasonable conclusions required that all major factors influencing lightning trouble be considered and all data be reduced to a common basis.

4. Because of the many factors involved, it has not been possible to determine thus far whether there is a material difference between the susceptibility to lightning trouble of grounded and ungrounded systems.

5. Low ground resistance may be obtained at low cost by connecting the arrester ground wire to the secondary circuit grounded neutral.

6. Customer interruptions from trouble on the primary system far exceed those from trouble on the secondary system.

7. The number of customer interruptions of less than 5 min. greatly exceeds the number of those of more than 5 min.; however, based on customer-hour interruptions, the order is reversed.

8. The major number of customer-hour interruptions due to all causes occur during electrical storms. At least one-half of these are attributable directly to lightning disturbances.

9. Lightning protection of distribution systems has been found to be of major importance from the standpoint of improving service continuity. (A.I.E.E. Paper No. 32-20)

## Equivalent Circuits

By
F. M. Starr[6]

EQUIVALENT circuits have been used from time to time in the solution of various magnetic and electrical problems. They have been found valuable in that they clarify the problem, simplify the analysis, and provide a means of replacing magnetic coupling with pure impedance links, thereby permitting the use of the calculating board for solution.

A particular problem has prompted a new study of representing a system of coupled circuits by an equivalent composed of pure impedance links. This problem arose primarily through the difficulty of representing adequately on the calculating board, groups of parallel transmission lines in which zero phase currents were flowing. In order to represent such a group on the calculating board it is necessary to replace the group with an equivalent circuit in which mutual impedance between the lines is simulated by pure impedance links. Closely related to the problem of coupled circuits is the general network problem.

In the present study the general equivalent mesh for the $n$-winding transformer is derived, as well as that for the mesh equivalent of the general network having $m + 1$ points of entry. These provide a background for the study of system networks involving groups of parallel transmission lines in such a manner as to simplify the problem greatly. These methods are perfectly general and may be applied to many other problems. (A.I.E.E. Paper No. 32-21)

## Transient Oscillations of Mutually Coupled Windings

By
L. V. Bewley[8]

IN THE PAST, the mathematical analysis of transient oscillations in transformer windings has been based upon a single winding having self and mutual inductances between its turns, capacitances along the stack and to ground, and, in one instance, resistances representing the losses. Such a circuit ignores the presence of secondary circuits, but strangely enough proves adequate to describe the internal high frequency transients of the winding under consideration, not only qualitatively but quantitatively as well. Cathode ray oscillograms, however, do show some difference in the characteristics of the oscillations, depending upon the terminal connections of the secondary circuit. Also, there is nothing in the single winding theory of transformer oscillations relative to the internal oscillations of the secondary circuit.

A mathematical study has been made of the oscillations occurring in the mutually coupled primary and secondary windings of a transformer when one of the terminals is subjected to the impact of a traveling wave. Solutions for grounded and open terminal conditions are obtained, but the general solution for any impedances at the terminals is not attempted, except for the initial distribution. (A.I.E.E. Paper No. 32-4)

## Geometrical Circuits of Electrical Networks

By
R. M. Foster[14]

IF ALL THE ELECTRICAL properties of a given electrical network are abstracted, there remains a geometric circuit completely characterized by the sets of branches terminating at the various vertexes. The use of such geometric circuits in place of the networks is desirable in the solution of a number of different problems. A successful application of this method requires to start with a complete enumeration of all distinct circuits classified according to certain specified properties.

In the present study enumerations of geometric circuits have been made, classified according to two different parameters, the nullity (number of branches minus number of vertexes plus number of separate parts) and the rank (number of vertexes minus number of separate parts). The geometric circuits which are symmetrical with respect to all branches and all vertexes, also have been listed. (A.I.E.E. Paper No. 32-22)

## The Breakdown of Glass With Alternating Potentials

By
N. D. Kenney[15]
A. M. Luery[16]
J. D. Moriaty[17]

THE FAILURE of solid dielectrics does not take place by one mechanism of breakdown but by several, different laws governing each type of failure. For some time thermal breakdown has been established as one of the mechanisms of puncture, and in 1928 there was found a type of breakdown in which the potential gradient is independent of temperature and thickness. This latter was spoken of as in the disruptive region. In 1929 a third type of breakdown was found lying between the previous two, and was termed as in the intermediate region.

These former experiments were conducted with direct potentials and additional experiments have been made recently to determine the results with alternating potentials. Glass was used as the test material.

It was demonstrated that three distinct regions of breakdown are obtained with alternating current, similar to those with direct current. In the disruptive and intermediate regions, it was found that breakdown occurs at an alternating peak voltage approximately equal to the direct breakdown voltage, while in the thermal region breakdown occurs at an alternating peak voltage somewhat lower than the direct breakdown voltage. (A.I.E.E. Paper No. 32-23)

## The Predetermination of the A-C. Behavior of Dielectrics

By
J. B. Whitehead[5]
A. Banos, Jr.[5]

CHARGE and discharge currents of any type of dielectric under continuous potential make it possible to predict accurately the loss, power factor, and capacity at 60 cycles. This is done by an empirical determination of the equation for the relaxation function of the dielectric at a given temperature, followed by the application of von Schweidler's method. The method developed is available at any frequency, provided the continuous potential charge and discharge currents may be measured over initial time intervals comparable with the alternating period.

A convenient and sufficient expression for the relaxation function is shown in this paper to be a sum of three exponentials. Further, experiment and analysis prove that the method of three exponentials predicts accurately the a-c. behavior of a dielectric at 60 cycles. The usual forms of irreversible conduction encountered also are defined and classified. The case in which the initial constant current does not obey Ohm's law has been considered analytically as regards its contribution to the a-c. behavior. (A.I.E.E. Paper No. 32-45)

## Relationships Among the Magnetic Properties of Magnet Steels and Permanent Magnets

By
K. L. Scott[19]

OPEN CIRCUIT remanence of magnet steels is the magnetic induction at the magnetic equator of a permanent magnet with no external magnetizing or demagnetizing force. A new relationship has been found connecting the open circuit remanence of a permanent magnet with the factors determining its value. By plotting the ratio of remanence to residual induction as the ordinate, and using as the abscissa the ratio of the product magnet lengths times square root of coercive force to the product of equivalent diameter times the square root of residual induction, a curve is obtained which appears to be general and valid for all kinds of magnet steel.

Various quantities have been proposed for use as criteria of the magnetic quality of magnet steel, the quantity having the greatest theoretical justification being the maximum value of the product of the coordinates of the demagnetization curve for a given field, where the demagnetization curve is the portion of the hysteresis loop between residual induction and coercive force. Experimental justification of the validity of this criterion has been secured. However, it is approximated by the product of residual induction and coercive force, and as this latter quantity can be determined with less effort, it is preferable for routine use. (A.I.E.E. Paper No. 32-24)

## Proposed Definition of Terms Used in Power System Studies

By
H. K. Sels[10]

THE INSTITUTE'S subject committee on definitions has submitted its report on terminology for power system interconnection and stability studies. The report covers the five following general divisions: interconnection terms, stability terms, active power and reactive voltampere conventions, synchronous machine quantities, and response of excitation systems. In preparing its report the committee has reviewed technical literature and consulted representatives of members of various A.I.E.E. committees.

The definitions presented are descriptive and cover the field practically in its entirety. While many of these may be considered arbitrary, they have been chosen in the best interest of the profession. Their general adoption will lead to a better mutual understanding with less possibility of confusion and controversy on technical questions. (A.I.E.E. Paper No. 32M2)

## Experience with Electrical Stability of Conowingo Station of Philadelphia Electric Co. System

By
R. A. Hentz[13]
J. W. Jones[13]

A BRIEF description of the Philadelphia Electric Company system with particular reference to the features influencing stability of the Conowingo hydroelectric station is

given in this paper. It summarizes the various calculations and tests associated with the stability problem, and presents a record of operating experience from a stability standpoint during four years of service.

Several cases of instability due to line faults have occurred. A thorough study of the matter was undertaken and as a consequence changes were made in the equipment and system set-up, involving the development and installation of higher speed circuit breakers and relays.

Detailed records are given for all faults on those parts of the system intimately associated with the Conowingo development. These records show the improvement in stability obtained by the changes in the system and indicate attainment of a generally satisfactory condition. **(A.I.E.E. Paper No. 32-25)**

## Generalized Stability Solution for Metropolitan Type Systems

By
S. B. Griscom[2]
W. A. Lewis[2]
W. R. Ellis[2]

STABILITY studies of metropolitan type systems may be profitable not because instability has been a serious operating problem, but because such studies often may permit more reliable or economical layouts to be utilized safely. A simplified method for determining the degree of stability of any layout of a metropolitan type system is presented in this paper.

General stability curves are given by means of which the transient stability during faults may be determined. The results are obtained as the permissible fault duration in terms of certain indexes of the system and fault. For a particular fault these indexes may be found from a short-circuit study made on a d-c. calculating board or its equivalent; only three readings are required to obtain the result. **(A.I.E.E. Paper No. 32-26)**

## An Induction Motor with Paralleled Rotor and Stator

By
A. G. Conrad[24]
R. G. Warner[24]

A LITTLE known method of operating induction motors is to parallel the rotor and stator windings. When this is done the pull-out torque as a motor is approximately doubled and the continuous horsepower output may be increased; as an induction generator, the maximum kva. output is increased. The machine may be operated simultaneously as a motor and as a generator. For heavy loads the efficiency is higher than that of the same motor operated with its sliprings short-circuited; and if the motor is to operate over a wide range, maximum efficiency may be secured by using a switching arrangement to short-circuit the rings at light load.

By paralleling the rotor and stator windings the rating of a given motor may be increased, the initial cost of a motor required to drive a given load will be less, and the no-load losses may be made smaller. If the ratio of stator to rotor currents is other than approximately 1:1, the windings may be paralleled through an auto-transformer. This should improve performance, since the transformer will by-pass part of the low frequency current that ordinarily would flow through the supply transformers. Tests on a machine with rotor and stator paralleled directly, indicated two disadvantages: the machine was noisy and the exciting current was high. This, however, might be eliminated by special designing. **(A.I.E.E. Paper No. 32-27)**

## Some Considerations in the Design of Damper Windings For Synchronous Motors

By
C. C. Shutt[2]

EXTENSION of the application of synchronous motors to include more specialized fields requires that the design of damper windings for special starting performance become a more exact art. Possibilities and limitations in the performance which may be obtained by variation of the damper winding design are brought out by classification of the various types of these windings.

Damper windings may be classified arbitrarily as low reactance and high reactance types. The low reactance windings include those made up of round or rectangular bars of such size that skin effect has only a negligible influence upon the distribution of the current in the bar. These windings are well suited to give a high ratio of torque to kva., especially during the initial part of the starting period. Many other types of performance including fairly uniform torque over the starting period, or a low starting torque with high pull-out torque or a relatively low kva., can be obtained with high reactance windings. These include all forms of double-deck windings as well as bars which are subject to appreciable skin effect; also single-deck windings, the characteristics of which change noticeably as the motor comes up to speed. **(A.I.E.E. Paper No. 32-28)**

## Power Losses in Electrolytic Condensers

By
F. W. Godsey, Jr.[26]

ELECTROLYTIC condensers on a-c. circuits have higher power losses than would be expected from the leakage currents and electrolyte resistances. Likewise, losses change with the applied voltage, temperature of the cell, the frequency of the applied voltage, and with external circuit conditions governing current wave shape in such ways that it is almost impossible to predict results in advance. When a sine wave of voltage is impressed the current wave usually contains large harmonics, indicating a non-linear function in the impedance of electrolytic condensers. Increases in voltage, temperature, frequency, and concentration of the electrolyte also cause increases in the harmonics in the current wave.

A film on the anode surfaces saturated with the electrolyte solvent would explain the characteristics as measured and also make it possible to predict characteristics with some accuracy. Ion penetration of the outer regions of the film, and a comparatively continuous film near the anode, explain the non-linear characteristics. The variation of the electrolyte potential can be predicted on this basis, and power losses also are more easily predictable. **(A.I.E.E. Paper No. 32-30)**

## Film Characteristics of Electrolytic Condensers

By
F. W. Godsey, Jr.[26]

ELECTROLYTIC condensers of the film forming type have some interesting characteristics which have never been satisfactorily explained. Extremely thin oxide or hydroxide films, formed on the surface of the metal anodes, seem insufficient in themselves to explain the complete action. Likewise, an electromotive equilibrium is insufficient to explain the action.

---

[24] Yale University, New Haven, Conn.

[26] Safety Car Heating & Lighting Co., New Haven, Conn.

Electrolytic condensers with extremely low applied voltages show large variations in measured capacity from high voltage measurements. The results indicate a film in which ion penetration plays a large part. Assuming the presence of a film saturated with water as the dielectric overcomes a number of former obstacles and lessens the necessity for the very thin films formerly assumed. (A.I.E.E. Paper No. 32-31)

## Electrical Precipitation

By
A. W. Simon[27]
L. C. Kron[27]

COTTRELL treaters have found many applications in various industries for the recovery or removal of smoke, dust, and fume particles from their containing gases. Precipitation efficiency, or percentage removal, depends upon a number of fundamental variables. A study made of these factors has placed the process on a more quantitative basis than formerly was possible.

Experiment shows in general that the precipitation efficiency increases with the treatment time, voltage, current, and power, according to a curve which partakes of the nature of that for a condenser charge; in other words, the relationships are exponential, and the cleaner a gas becomes the harder it is to remove more particles from it. The value of operating voltage above that necessary to produce corona was found to have little effect upon the cleaning efficiency, but the current flowing between electrodes and through the gases within the precipitator is of considerable importance to efficiency. (A.I.E.E. Paper No. 32-32)

## Commutation Considered As a Switching Problem

By
R. E. Hellmund[2]
L. R. Ludwig[2]

THE USUAL commutation theories deal with the reversal of the current in the commutating coil and with means for bringing about such reversal either along a straight line or curve. The principal object in such studies is to accomplish commutation without excessive current densities under the brush. Frequently, however, it is impossible to realize this, and the phenomenon which results is essentially one of switching. With this new concept in mind, factors may be studied which previously have not been considered.

For example, the mutual and self-inductance of the windings and their capacity may have an effect upon the energy to be dissipated during commutation. With this concept of switching in mind it can be seen that there may be a difference in commutation between shunt, series, or separately-excited machines, and with laminated or solid field structures, although the speed, current, and commutating fields are the same. Also, a-c. commutator machines may be affected by the transformer to which the machine is connected. Interesting results are obtained with two series-connected motors on a motor car, especially in a-c. motors having no damping effects in their field structure. During certain conditions each motor may have an effect upon the commutation of the other; this is explained readily by the switching theory. In general, the commutating phenomena cannot be considered as analyzed completely unless the possibilities of the switching phenomena as influenced by the various connected circuits have been given due consideration. (A.I.E.E. Paper No. 32-33)

## Equalizing Currents in the Armature of a D-C. Machine

By
R. M. Baker[2]

WHEN THE PARALLEL type winding was first used on the armatures of large d-c. machines, it was almost impossible to obtain sufficiently good magnetic balance of the main field circuits to permit satisfactory operation. In 1896 the idea was conceived of automatically balancing the flux in the main poles by connecting together those points on the armature which normally should be of the same potential. These equalizing connections have proved themselves capable of taking care of considerable unbalance in the same field; in fact their performance has been so satisfactory that little study has been given to the details of this action.

An increased knowledge of the behavior of these currents, however, has been secured by an analysis which is unique in that it is based upon experimentally determined curves of variation in equalizing current in an actual machine. The analysis shows definitely how these currents act to correct the unbalance causing their flow. It was found that even with very small inequalities of the main pole gaps the equalizing current in an armature coil may reach a peak value as high as 25 per cent of the full load coil current, several times each revolution of the armature. It has been shown also that the oscillograph is very useful in studying the behavior of equalizing connections, and that empirical results are obtainable without much difficulty. The securing of similar relations by an analytical method would be very complex. (A.I.E.E. Paper No. 32-5)

## Calculation of No-Load Damper-Winding Loss in Synchronous Machines

By
E. I. Pollard[2]

THE NON-UNIFORM nature of the air-gap due to the presence of alternate teeth and slots on the stator of synchronous machines results in a non-uniform distribution of flux density at the surface of the rotor. These pulsations in the air-gap induction produce pole-face loss. When a damper winding is present the pulsations link the damper bars producing circulating currents causing an additional loss which is designated by the term "no-load damper winding loss." The magnitude of this loss is found to vary from practically zero to as much as eight times the pole-face loss, or to as much as half of the total no-load core loss. A method now has been developed for calculating the no-load damper loss, based on theoretical considerations.

This study has indicated several ways by which the damper loss may be minimized. Changes in design to reduce pole-face loss also generally decrease the magnitude of damper loss, but the requirements in fundamental proportions of the machine usually require that these changes should not be made. The reduction of loss may be secured by keeping the number of bars on the machine and the bar resistance low. Perhaps the most powerful method of reducing loss is by adjustment of the ratio of rotor slot pitch to stator slot pitch. (A.I.E.E. Paper No. 32-34)

# Sine Wave Generators

By
L. P. Shildneck[6]

CERTAIN applications, particularly testing, require a sine wave of generator voltage under all load conditions, and the round-rotor type of sine wave generator consequently was developed. The stator is similar to that of a salient-pole machine but for the field a round punched rotor is used with a double layer winding distributed in evenly spaced slots.

A comparison of various types of these windings shows that three newly developed connections called the *X*, *U* and *W* types are superior to the old *V* and *Y* types, in that 15 per cent or more increase in output can be secured from the rotor without increasing the maximum coil temperature rise or impairing the voltage wave shape. This change is wrought by eliminating the undesirable features of the old types; namely, too few active coils in the *V* type, and unequal leg heating in the *Y* type.

The analysis made in this connection is quite general and directly applicable to all round-rotor synchronous machines with double layer rotor coil windings as exemplified by sine wave generators and also synchronous induction motors. By selection of the proper connections any one of the factors desired, wave form, efficiency, and heating, can be stressed to any desired degree. (A.I.E.E. Paper No. 32-35)

# Engineering Features of Three-Power Locomotives

# Motors for 3,000-Volt D-C. Multiple Unit Cars

By
J. C. Aydelott[28]

A NEW MULTIPLE unit car motor incorporating many novel features of design was developed for the electrification of the suburban service of the Delaware, Lackawanna & Western Railroad, the first installation of multiple unit suburban service in this country employing a trolley potential of 3,000-volts direct current. The absence of trouble in commencing and maintaining service marks the whole electrification program.

There now are 564 of these motors in service on the Lackawanna railroad, and between August 1930 and June 1, 1931, 4,500,000 car miles have been operated with only two train delays chargeable to motor failure. During the period of initial operation the motors have been remarkably free from flashovers, insulation failures, and mechanical troubles. This preliminary operation indicated also that the maintenance expense will be unusually low. The securing of the many desirable features in motor design, and the consequent successful operation, may be attributed largely to the development of new design features. (A.I.E.E. Paper No. 32-36)

# Temperature Rise of Ventilated Railway Motor Armatures

By
D. A. Lightband[2]

THE CALCULATION of temperature rise and of time-temperature curves of a railway motor for which only preliminary design data are available, usually presents considerable difficulty. Modern railway practise demands increasingly large power units in a limited space, so that accurate methods are necessary for the predetermination of temperature rise. This must be used as a basis for guaranteed ratings and time-temperature curves in the application of a motor to a complicated service cycle.

Equations derived from the usual theory of heat flow between related bodies give a method for calculating the temperature rise of the armature in a new design of motor, for any time interval and load condition. Consistent results are given when applied to motors of widely varying size. By making certain assumptions the armature can be reduced to a simple equivalent model consisting of two conducting bodies separated by an insulating wall, and equations resulting from an analysis of this thermal system form a practical method of calculating time-temperature curves of an armature from preliminary design data. **(A.I.E.E. Paper No. 32-7)**

# Preparing Substations for Electric Operation

By
L. B. Curtis[29]

APPROXIMATELY forty substations are involved in the extensive electrification program recently announced for the Pennsylvania Railroad between New York and Washington; eleven of these already are in operation. A definite program for testing these substations before they are placed in operation has been evolved, and this procedure has been combined into a single set of test instructions.

The tests are separated into three groups: (1) preliminary tests without d-c. control or a-c. power; (2) tests with d-c. control but without a-c. power; and (3) tests with d-c. control and a-c. power. These test instructions are unusually complete and cover all possible sources of error which might interfere with the successful operation of the substation when it is placed in service. (A.I.E.E. Paper No. 32-37)

# The Time Services of the U.S. Naval Observatory

By
J. F. Hellweg[31]

ONE HUNDRED and one years ago the Naval Observatory was created. Since then it has had the determination and broadcasting of the nation's time. This is broadcast in mean solar time although kept in sidereal time. Measurement of time is based upon the earth's rotation and is very accurately observed and calculated. Observations are made by transit instruments with which the successive transits of predetermined stars are observed.

Because of its increasing importance in the nation's daily life great accuracy is demanded of the time service, and means of increasing this accuracy constantly are being sought. A new clock vault now is nearing completion. It will contain precision timepieces maintained at constant temperature and pressure at all times. The new clocks now are under construction and it is hoped that with this equipment, and modifications which are being planned, it will be possible to extend the time service, increase its accuracy, and add to the number of broadcasts per day. (**A.I.E.E. Paper No. 32-38**)

## Time Services of the Telegraph Companies

By
G. W. Janson[32]

THREE CLASSES of time service are distributed by the telegraph companies. The first of these, commonly known as "noon beats" comprises the transmission during a three-minute period ending at noon eastern standard time of a series of electrical impulses originating from the naval observatory at Washington, D. C. This service is used very largely for correcting local master clocks throughout the United States once each day. The second time service commonly known as "jewelers' beats" comprises a similar transmission throughout the day of a series of coded impulses distributed in each locality by a master clock. These beats are used principally by jewelers for regulating timepieces.

The most extensive distribution of correct time by the telegraph companies is the automatic correction of clocks. The Western Union Telegraph Company's synchronizing system corrects about 120,000 clocks of which 95 per cent are rented to subscribers. These clocks operate independently but are reset to the correct time each hour by the telegraph synchronizing service. (**A.I.E.E. Paper No. 32-39**)

## Synchronous Electric Time Service

By
H. E. Warren[33]

PREVIOUS to 1916 no commercial a-c. system was regulated with sufficient accuracy of speed to enable its use for indicating time. Two devices then were developed making commercial a-c. time service possible. The first of these was a self-starting synchronous motor which utilized residual magnetism to enable the rotor to start and run at synchronous speed. The second consisted of an indicating instrument which would show to a generating station operator, directly in terms of time, deviations of average frequency from standard.

About 1928 several new varieties of synchronous motors suitable for use in clocks were developed. These may be divided into two classes, and self-starting and non-self-starting. The latter generally has toothed soft steel rotors, while the self-starting motors utilize a-c. fields with rotating components brought about by the use of shading coils. Both types now have been developed to require small power input and to eliminate hum. These are now being applied to many timing devices other than clocks.

The standardization of average frequency is of great value to the power companies in many ways other than the furnishing of time services. Further increase in the accuracy of control is to be expected from the use of automatic frequency control equipment which now is being developed. (**A.I.E.E. Paper No. 32-40**)

## New Key West-Havana Carrier Telephone Cable

By
H. A. Affel[14]
W. S. Gorton[18]
R. W. Chesnut[18]

A NEW SUBMARINE cable was laid recently between Key West and Havana to furnish increased telephone facilities between the United States and Cuba. This is the longest deep sea telephone cable in existence and also is unique in being the longest telephone cable circuit without intermediate repeaters and without inductive loading. The new cable operates at frequencies up to about 28,000 cycles per second; it has a single central conductor with concentric tape return, and employs the newly developed material paragutta for insulation. Due to the smaller dielectric constant and to the smaller leakance, the cable is much smaller in size than any of the three other cables between these countries.

A carrier telephone system provides three telephone channels and as ultimately developed, a still greater number of facilities may be made available. A large number of noise sources was investigated and the necessary methods for eliminating these were installed.

## The Development of a Handset for Telephone Stations

By
W. C. Jones[18]
A. H. Inglis[14]

A NUMBER of factors contribute to the difficulties involved in the design of a telephone handset which gives as good service performance as a deskstand. The handset transmitter for example not only is used in a wider range of positions but also is moved much more frequently, so that wider variations are experienced in its characteristics. The more severe use to which the handset is subjected requires special design measures to prevent an appreciable shortening of useful life.

Further difficulties are introduced by the close physical connection of the receiver and transmitter, in that "howling" tends to be set up. Also, the distance between the receiver and transmitter must be such as to be convenient for the user without introducing unnecessary losses in voice transmission in air.

The handset has been developed so that it overcomes all these difficulties and is interchangeable with the deskstand in existing telephone plant without important reaction on either transmission or signaling performance. That the design meets the wishes of the public is evidenced by the steady increase in demand to more than 1,000,000 sets per year at the present time.

## An Automatic Concentration Unit for Printing Telegraph Circuits

By
G. S. Vernam[34]

WHEN a number of lightly loaded telegraph circuits terminates at a central telegraph office, and the number of messages over each circuit is insufficient to keep the operator fully employed, these circuits usually are grouped together on a switchboard or "concentrator," so that a single operator can send and receive messages over any line of the group.

Printers or "teletypewriters" of the so-called "start-stop" type are being used to a large and increasing extent on such lightly loaded circuits, both by the telegraph companies and by private customers. As a result, concentration units are being used to an increasing extent for printing telegraph circuits.

---

[32] Western Union Telegraph Co., New York, N. Y.

[33] Warren Telechron Company, Ashland, Mass.

[34] International Communications Laboratories, New York, N. Y.

Manually operated telegraph concentrators have been in use for many years, but an automatic concentrator now is being employed to permit the individual printer operators to set up their own connections. Outward calls are established by dialing without requiring multiple turrets or switching operators, and inward calls to idle positions can be established automatically without the delay involved in manual switching operations. Step-by-step automatic switches and calling dials are used, a number of special features being included.

## Carrier Application to a Telegraph Plant

By
R. E. Smith[34]
L. A. Kelley[34]

THE REQUIREMENTS for carrier systems in telegraph plants differ somewhat from those in telephone plants. Primarily these differences are due to the fact that telegraph plants are based upon the wide use of d-c. telegraph circuits which can be operated fairly successfully on a ground return basis. Furthermore, the operating energy levels of the various circuits on the same lead are not restricted by the presence of other types of communication circuits occupying a frequency transmission range other than that required for d-c. telegraph signals. Other equally important factors enter into the problem, and are outlined in this paper.

A description also is given of the transmission and equipment features of the system recently developed to meet the specific needs of the Postal Telegraph-Cable Company. The system is now in commercial service in the extensive open-wire plant of this company. Performance characteristics showing the capabilities of the system also are included.

## Forces of Electric Origin in the Iron Arc

By
F. Creedy[35]
R. O. Lerch[35]
P. W. Seal[35]
E. P. Sordon[35]

A NUMBER of phenomena are present in overhead arc welding, for which no adequate explanation has been possible. Among the questions are: (1) what is the force that causes the molten drop to travel across the arc face from the electrode to the work, (2) why is it that the drop is detached with explosive violence rather than gradually? In an attempt to determine the electric origin of these forces in high current metallic arcs, the magnified image of an arc was projected on a screen by means of a lens. In this manner, relations between the electrical forces, arc currents, and arc lengths were studied.

General conclusions may be drawn from these results indicating that the force which detaches the globule from the welding rod may depend upon the "pinch effect" due to the magnetic field tending to force the outer portions of a conductor toward the center. As the cross-section of the area between the globule and the electrode becomes smaller, the pressure is increased as the square of the current density. The force tends to sever the part still attached. This appears to be the cause of the explosive violence with which the globule is detached. It appears that as soon as the globule is separated it is carried over by the force of the reaction resulting from the emission of minute particles at high temperature. **(A.I.E.E. Paper No. 32-41)**

## An Improved A-C. Arc Welder

By
A. M. Candy[2]

THE COST OF APPARATUS for arc welding with the a-c. arc is less than that for the d-c. arc. In spite of this the d-c. arc has been used much more extensively because: the open circuit voltage of the a-c. welder was about double that of the d-c. equipment with a consequent increased life hazard; the a-c. arc was much more difficult to strike and hold; and it also drew a low power factor current from the line.

By imposing a high frequency on the welding circuit all these disadvantages of the a-c. arc welder have been overcome. The voltage developed by the oscillator circuit is sufficiently high to start the discharge in the arc just before the electrode contacts the work; for this reason the arc starts easily, sticking of the electrode to the work is eliminated, and a lower voltage may be used for the basic frequency arc. The necessity for a high leakage reactance to throw the voltage and current out of phase so as to maintain the current when passing through zero is eliminated. Consequently the power factor is considerably improved; in fact it is approximately 90 per cent, which is even better than that of an induction motor driving a d-c. generator for d-c. welding.

The quality of the weld made with this improved a-c. welder is equal in every respect to that of d-c. welds. Because of the low no-load losses, the low investment charges, and low maintenance costs resulting from the absence of any rotating parts, the a-c. welding equipment is very economical to operate especially when welding materials of 16 gage or less. **(A.I.E.E. Paper No. 32-42)**

## Recent Developments in Design of Arc Welding Generators

By
K. L. Hansen[36]

A DROOPING volt-ampere characteristic is required of an arc welding generator in order to overcome the instability of the arc due to its negative resistance characteristic. Where there are abrupt changes in the arc resistance, as in metallic arc welding, this requirement becomes complex and exacting. Other desirable design features are as follows:

1. Elimination of the external reactor sometimes used to smooth out current fluctuations.
2. Reflection of current impulses in the main circuit back into the field to quicken field flux changes and thereby make the machine more responsive to changes in the external resistance.
3. Elimination of the exciter without resorting to the two-pole armature four-pole field structure.
4. Elimination of all regulating rheostats and switches without interfering with the desirable characteristics of the generator.

In a new completely self-contained arc welding generator, the first two of the objects enumerated above have been obtained by a novel design of the commutating winding, shunt windings, and main poles, and by adding a special winding consisting of one turn short-circuited upon itself. Suitable excitation is secured by two sets of auxiliary brushes spaced from 50 to 60 electrical degrees ahead of the main brushes. Adjustment of the brushes enables the current to be varied. The resultant machine is very fast in response to variations in external resistance, and retains over a wide range of operation the characteristics desired in an arc welding generator. **(A.I.E.E. Paper No. 32-43)**

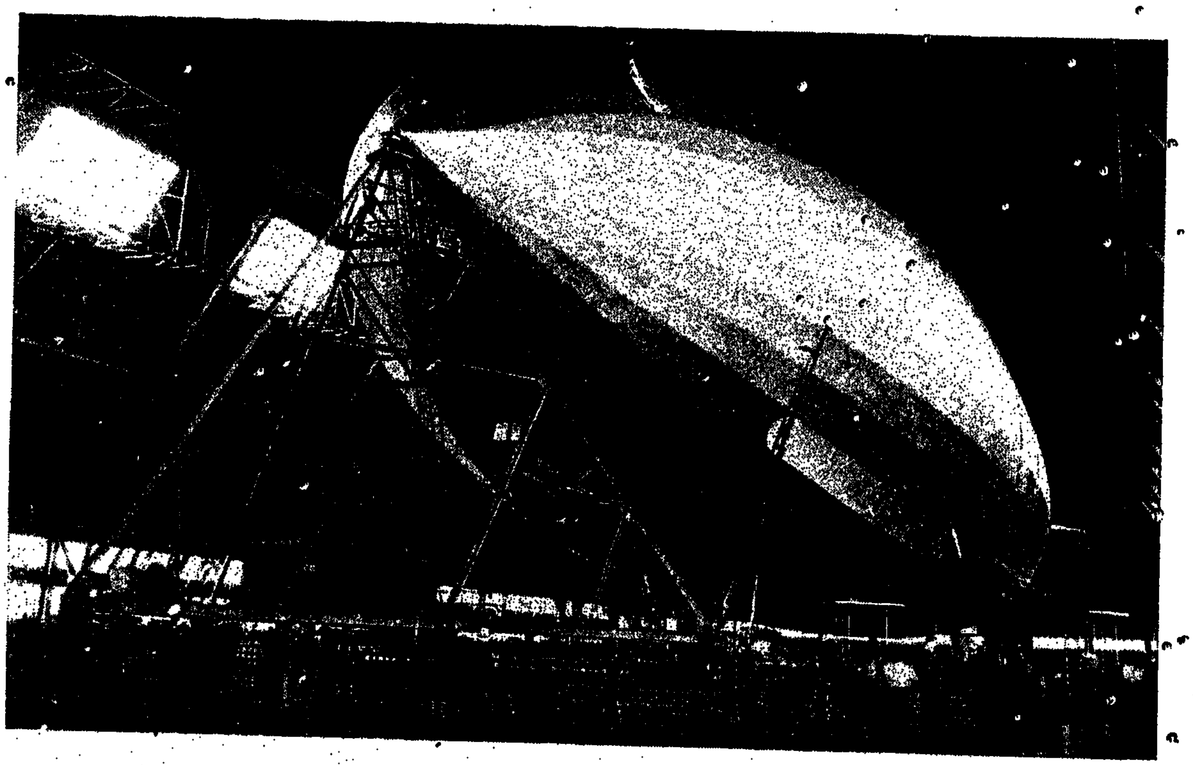
# Winter Convention Arrangements Completed

## Fourteen Technical Sessions and Other Features Offered

EVERYTHING is in readiness for the 1932 A.I.E.E. winter convention which will be held with headquarters in the Engineering Societies Building, 33 West 39th Street, New York, N. Y., January 25-29. An excellent schedule of events embracing fourteen technical sessions, a variety of inspection trips and social functions, and a special program for women guests has been completed.



The U.S.S. Akron "riding at anchor" in the Lakehurst, N. J. "dock"

### Technical Sessions

Three of the technical sessions comprise important symposiums: (1) distribution circuit lightning protection, (2) system stability, (3) time and time services. Lightning as it is related to transmission lines has been treated often, but relatively little has been brought forth on the subject of distribution circuit lightning protection. Consequently this session should fill a gap in this field. System stability and its intricate relations when systems are interconnected offer a timely topic of interest to many groups. Valuable data and experience gained in this particular field will be brought out through the cooperation of manufacturing and operating companies. Likewise the symposium on time and time services will present valuable and interesting information on this modern phase of the art. With eleven other specialized sessions the program leaves little to be desired from a standpoint of technical interest.

Detailed information concerning this convention was published on p. 971-2 of Electrical Engineering for December, 1931. Additional information and a few minor changes are outlined in the following paragraphs.

The session on research which formerly was scheduled for Tuesday afternoon will be held on Wednesday morning in parallel with the symposium on stability. The first paper formerly listed in the session on research "Some Fundamental Theory and Experiments on Electrical Precipitation" by A. W. Simon and L. C. Kron, will be presented Thursday morning in the electrochemistry-metallurgy session.

The selected subjects session will be entirely devoted to a symposium on steam power station auxiliary drives.

A paper "Preparing Substations for Electric Operation" by L. B. Curtis, Pennsylvania Railroad, has been scheduled for presentation in the session on transportation.

### John Fritz and Edison Medals

Two of the most highly prized rewards for engineering accomplishments will be presented in the Engineering Auditorium on the evening of Wednesday, January 27.

The Edison Medal will be presented to Dr. Edwin Wilbur Rice, Jr., for his contributions to the development of electrical systems and apparatus and his encouragement of scientific research in industry.

The John Fritz Medal will be presented to Dr. Michael Idvorsky Pupin for his accomplishments as a leading scientist, engineer, and author, and as inventor of the tuning of oscillating circuits and the loading of telephone circuits by inductance coils.

Details of the award of the John Fritz Medal were published in Electrical Engineering, Nov. 1931, p. 911. Details of the award of the Edison Medal are published on p. 61 of this issue.

### Entertainment Features

A buffet supper (served by Louis Sherry) and smoker with entertainment will be held in the headquarters building on Tuesday evening, January 26. This informal occasion affords a splendid opportunity to renew old acquaintances and to make new ones. Tickets will be $3 per person.

The dinner dance, for many years an outstanding social event of the Institute, will be held in the Grand Ballroom of the Hotel Astor, Thursday evening, January 28. Tickets will be $6 per person. Reservations may be made in advance for tables seating eight or ten people.

For women guests a specially planned program has been arranged by the ladies' entertainment committee under the chairmanship of Mrs. E. B. Meyer.

On Wednesday, January 27, 6:30 p.m.,

graduates of Columbia University will dine at the Columbia University Club, 4 West 43rd Street, in an informal get-together dinner which will finish in time to enable them to attend the regular evening session. Price $1.50. For reservations address A. D. Hinckley, Columbia University.

### REGISTER IN ADVANCE

Each member should register in advance by mail, thus permitting the committee in charge to have the badges ready, saving time and reducing congestion at the registration desk. A card for this purpose was included in the mailed announcement.

Reservations for hotel accommodations should be made by writing directly to the hotel chosen. Rates for some of the hotels were listed in the mailed announcement.

### REVISED SCHEDULE OF EVENTS

Monday morning and evening have been left open for committee meetings. Capital letters A, B, etc., denote technical sessions.

**Monday, January 25**

10:00 a. m. Registration
2:00 p. m. Opening of Convention
A—Protective Devices
B—Instruments and Measurements

**Tuesday, January 26**

10:00 a. m. C—Symposium on Distribution Circuit Lightning Protection
D—General Circuit Theory
2:00 p. m. E—Selected Subjects
6:00 p. m. Buffet Supper and Smoker

**Wednesday, January 27**

10:00 a. m. F—Symposium on System Stability
G—Research
1:15 p. m. Inspection Trips
2:00 p. m. Board of Directors Meeting
8:30 p. m. Edison Medal and John Fritz Medal Presentations

**Thursday, January 28**

10:00 a. m. H—Electrical Machinery
I—Electrochemistry and Electrometallurgy
2:00 p. m. J—Electrical Machinery
K—Transportation
7:30 p. m. Dinner Dance

**Friday, January 29**

10:00 a. m. L—Symposium on Time and Time Services
2:00 p. m. M—Communication
N—Electric Welding

### INSPECTION TRIPS

Attention of all of those who will attend the convention is called to the fact that members of the inspections trips committee will be pleased to assist in the making of necessary arrangements for the visiting of neighboring plants or other points of special interest. The committee asks that members make known their desires as soon as possible after arrival.

**U.S. Naval Air Station and U.S.S. Akron**

The great Navy dirigible *U.S.S. Akron*, the building of which was started November 7, 1929, and completed August 8, 1931, when it was christened by Mrs. Herbert Hoover before approximately 150,000 people, now is stationed at the Naval Air Station at Lakehurst, N. J. The committee has arranged for an inspection of this world famous battleship of the air. Through the hospitality of the commanding officer of the air station, the hangars will be visited Wednesday afternoon, January 27, when both the *Akron* and the *Los Angeles* are scheduled to be there. Special arrangements are being made with the railroad, which will furnish accommodations at a very reasonable figure.

**Scenic Trip via George Washington and Bear Mountain Bridges**

During the last convention, an inspection trip was made to the George Washington Bridge, then under construction. This engineering monument with its 3,500 ft. suspension span, the longest in the world, is now completed and in service forming an important traffic artery between New York and New Jersey. Further up the Hudson River at Bear Mountain is another famous span which forms an important connecting link between the highways on either side of the Hudson River. A ride over the highways in this vicinity provides a magnificent motor trip. De luxe buses will, on Wednesday afternoon, January 27, start from the Engineering Societies Building, cross the new George Washington Bridge, travel north up the Hudson River on the top of the Palisades to the Bear Mountain Bridge, cross the Bear Mountain Bridge and return to the starting point via scenic New York State highways.

**New Jersey Industrial Area**

For those who would enjoy a bus trip through the industrial area of New Jersey, with brief stops at points of specific interest, a trip is in contemplation and will be described more fully in the convention literature.

**Other Points of Interest**

Opportunity will be afforded to those who wish to visit the installations of the neighboring utilities, railroad electrifications completed or in progress, or industrial and other enterprises which may command the interest of the members and their guests. Inspection privilege to visit the following places of interest has been accorded:

1. The Delaware, Lackawanna and Western Railroad Electrification
2. Roseland (N. J.) switching station of the Public Service Electric and Gas Company
3. 160,000-kw. tandem compound units of the Brooklyn Edison Company, and the company's research laboratory
4. East River generating station of New York Edison Company
5. New Eighth Avenue Subway substations
6. Vertical distribution in Empire State Building
7. Electrical Testing Laboratories
8. Lighting institute of the New York Electrical Society
9. New three-power locomotives of New York Central Railroad used for switching on West Side lines in New York City
10. Studio of Jenkins Television Corporation, where actual television broadcasting of dramatic sketches, and their reproduction as received on local receiver, may be witnessed
11. Lawrenceville (A.T.&T.) short wave radio station, and also control room at 24 Walker St., for ship-to-shore and transatlantic Service
12. Time service bureaus of New York Telephone Company, and Western Union Telegraph Company
13. Teletypewriter exchange service of American Telephone and Telegraph Company at 24 Walker St.
14. New York Museum of Science and Industry, where may be seen the new permanent exhibits relating to power, and electrical science and technology
15. New Lighting of the Statue of Liberty (See front cover)
16. Network protector exhibit and time control of street lighting circuits

200,000-kva. turbine-generator unit recently installed in the Brooklyn Edison Company's Hudson Avenue Station

## Institute Directors Hold December Meeting

The regular meeting of the A.I.E.E. board of directors was held at Institute headquarters, New York, December 4, 1931.

Present were: *President*—C. E. Skinner, East Pittsburgh, Pa. *Past-president*—W. S. Lee, Charlotte, N. C. *Vice-presidents*—H. P. Charlesworth, New York, N. Y.; L. B. Chubbuck, Hamilton, Ont.; A. W. Copley, San Francisco, Calif.; W. B. Kouwenhoven, Baltimore, Md.; T. N. Lacy, Detroit, Mich.; I. E. Moultrop, Boston, Mass.; P. H. Patton, Omaha, Neb. *Directors*—L. W. Chubb, East Pittsburgh, Pa.; A. B. Cooper, Toronto, Ont.; B. D. Hull, Dallas, Tex.; J. Allen Johnson, Buffalo, N. Y.; A. E. Knowlton, New York, N. Y.; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, New York, N. Y.; R. H. Tapscott, New

York, N. Y.; H. R. Woodrow, Brooklyn, N. Y. *National Treasurer*—W. I. Slichter. *National Secretary*—F. L. Hutchinson, New York, N. Y.

The minutes of the directors' meeting of October 23, 1931, were approved.

The following minute was adopted in memory of the late Dr. L. T. Robinson:

> In the keen appreciation of the loss sustained by the field of electrical engineering and by the American Institute of Electrical Engineers through the death on November 3, 1931, of Dr. Lewis Taylor Robinson, the board of directors of the Institute adopts this minute and directs that a copy be sent to Dr. Robinson's family:
>
> "In the passing of Lewis Taylor Robinson, there was removed from the profession of electrical engineering one of the men to whom that profession is most deeply indebted; who, as an Institute worker, gave generously of his time through service as manager and vice-president, and member for many years of the standards and many other committees; a man whose unselfish interest and devotion served as a steadying and guiding influence, and whose sound judgment and pleasing personality won for him throughout his long years of service the high respect of the many with whom he came in contact."

A report of a meeting of the board of examiners held November 24, 1931, was presented and approved. Upon the recommendation of the board of examiners the following actions were taken upon pending applications: 789 Students were enrolled; 45 Associates were elected; 7 applicants were elected to the grade of Member, and 15 were transferred to the grade of Member.

Approval by the finance committee of monthly bills amounting to $24,129.97 was ratified.

A resolution was adopted to the effect that the 1932 annual (business) meeting of the Institute will be held on Monday, June 20, at Cleveland, Ohio.

Appointments were made as follows: H. H. Barnes, Jr., as a member of the Edison Medal committee, succeeding Dr. L. T. Robinson (deceased); H. S. Osborne, successor to Doctor Robinson, as a representative of the Institute on the standards council of the American Standards Association; A. W. Berresford as an Institute representative on the board of trustees of the United Engineering Trustees, Inc., for the three-year term beginning January 1, 1932; and W. S. Barstow reappointed to the library board of the United Engineering Trustees, Inc., for the four-year term beginning January 1, 1932.

A communication from W. S. Barstow was presented, in which he advised of his intention to present to the Institute, a bronze bust of Thomas A. Edison (a replica of the marble bust presented last April to the Deutsches Museum, Munich, Germany) and the following resolution was adopted:

> RESOLVED, That the board of directors of the American Institute of Electrical Engineers hereby expresses to Mr. William S. Barstow, a former director and vice-president of this Institute and now president of the Edison Pioneers, its high appreciation of his action in presenting to the Institute a bronze bust of Thomas A. Edison, and directs that this bust be placed upon exhibition in a prominent place at Institute headquarters.

The following new by-law was adopted, defining the scope of the committee mentioned therein:

> The committee on economic status of the engineer shall consist of five members, and shall consider matters relating to the position, function, and responsibility of the engineer in the development of human welfare, and make reports and recommendations thereon to the board of directors. The committee shall cooperate with similar committees of other engineering societies, and shall also consider and report upon all matters referred to it by the board of directors, the president, and the national secretary.

In response to an invitation to be represented at the Seventh American Scientific Congress to be held in Mexico City, February 5-19, 1932, President Skinner was appointed as the Institute's delegate to this congress.

Upon invitation from the Kelvin Medal board of award (of England) to nominate a candidate for the award of the Kelvin Medal in 1932, the president was authorized to appoint a committee to report recommendations at the January meeting of the A.I.E.E. board.

The board accepted offers from Past-Presidents Ralph D. Mershon and William S. Lee each to donate a golf trophy (to replace the Mershon Cup which in June 1931 passed into the permanent possession of L. F. Deming of Philadelphia, and authorized the appointment of a committee to work out the details in connection with both trophies.

Consideration was given to a request from the Institute of Electrical Engineers of Japan for assistance in carrying out two projects under the Iwadare Foundation, as follows: (1) Sending Japanese electrical engineers to the United States each year to study, and (2) inviting each year distinguished electrical engineers from the United States to deliver several lectures in Japan. The appointment of a continuing committee to carry on this activity was authorized.

Approval was given to a proposal by The Engineering Foundation to establish a research procedure committee, consisting of one representative from each of the four national societies of civil, mining and metallurgical, mechanical, and electrical engineers, and two representatives of The Engineering Foundation. The president was authorized to appoint the Institute's representative on this committee. (President Skinner later designated L. W. Chubb, chairman of the Institute's committee on research.)

A report was received from G. L. Weller, the Institute's representative at the Fourth Pan-American Commercial Conference, held in Washington, October 5-13, 1931.

Other matters were discussed, reference to which may be found in this and future issues of ELECTRICAL ENGINEERING.

# A.I.E.E. Nominating Committee Announces Official Candidates for 1932

A COMPLETE official ticket of candidates for the Institute offices that will become vacant August 1, 1932, was selected by the national nominating committee which met at Institute headquarters, New York, December 3, 1931. This committee consists of fifteen members, one selected by the executive committee of each of the ten geographical districts, and the remaining five elected by the board of directors from its own membership.

The following members of the committee were present: C. T. Almquist, Norman, Okla.; F. J. Chesterman, Pittsburgh, Pa.; A. B. Cooper, Toronto, Ont.; A. W. Copley, San Francisco, Calif.; Bancroft Gherardi, New York, N. Y.; B. D. Hull, Dallas, Tex.; W. B. Kouwenhoven, Baltimore, Md.; T. N. Lacy, Detroit, Mich.; P. H. Patton, Omaha, Neb.; C. E. Rogers, Seattle, Wash.; C. E. Stephens, New York, N. Y.; R. H. Tapscott, New York, N. Y. (alternate for A. M. MacCutcheon, of Cleveland, Ohio); R. G. Warner, New Haven, Conn.; and F. L. Hutchinson, New York, N. Y., secretary of the committee. Past-President Bancroft Gherardi was elected chairman of the committee.

The following is a list of the official candidates as selected by the committee:

### FOR PRESIDENT

H. P. Charlesworth, vice-president, Bell Telephone Laboratories, New York, N. Y.

### FOR VICE-PRESIDENTS

North Eastern District (No. 1): J. Allen Johnson, chief electrical engineer, Buffalo, Niagara & Eastern Power Corporation, Buffalo, N. Y.

New York City District (No. 3): E. B. Meyer, vice-president, United Engineers & Constructors Inc., Newark, N. J.

Great Lakes District (No. 5): K. A. Auty, sales engineer, Commonwealth Edison Company, Chicago, Ill.

South West District (No. 7): G. A. Mills, chief engineer, Central & South West Utilities Company; vice-president, Pecos Valley Power & Light Company, Dallas, Tex.

North West District (No. 9): C. R. Higson, superintendent of distribution, Utah Power & Light Company, Salt Lake City, Utah.

### For Directors

G. A. Kositzky, chief engineer, The Ohio Bell Telephone Company, Cleveland, Ohio.

A. H. Lovell, assistant dean and professor of electrical engineering, University of Michigan, Ann Arbor, Mich.

A. C. Stevens, in charge, educational sales, General Electric Company, Schenectady, N. Y.

### For National Treasurer

W. I. Slichter, professor of electrical engineering, Columbia University, New York, N. Y.

The constitution and by-laws of the Institute provide that the nominations made by the national nominating committee shall be published in the January issue of Electrical Engineering. Provision is made for independent nominations as indicated in the following excerpts from the constitution and by-laws:

### Constitution

Sec. 31. Independent nominations may be made by a petition of twenty-five (25) or more members sent to the National Secretary when and as provided in the By-laws; such petitions for the nomination of Vice-Presidents shall be signed only by members within the District concerned.

### By-Laws

Sec. 23. Petitions proposing the names of candidates as independent nominations for the various offices to be filled at the ensuing election, in accordance with Article VI, Section 31 (Constitution), must be received by the secretary of the National Nominating Committee not later than February 15 of each year, to be placed before that committee for the inclusion in the ballot of such candidates as are eligible.

On the ballot prepared by the National Nominating Committee in accordance with Article VI of the Constitution and sent by the National Secretary to all qualified voters during the first week in March of each year, the names of the candidates shall be grouped alphabetically under the name of the office for which each is a candidate.

(*Signed*) National Nominating Committee
By F. L. Hutchinson,
Secretary

### Biographies of Nominees

That those not personally acquainted with the nominees may know something of them and their qualifications for the offices for which they have been recommended, brief biographical sketches of each are given herewith.

### H. P. Charlesworth

Harry Prescott Charlesworth was born in Haverhill, Mass., April 7, 1882. After graduation by the Massachusetts Institute of Technology in 1905 with the degree of Bachelor of Science, Mr. Charlesworth entered the engineering department of the American Telephone and Telegraph Company, then located in Boston. His early assignments had to do with the development of telephone circuits and associated apparatus. Later he was active for several years in the development of toll operating methods and the general related engineering problems involved in extending and improving telephone service.

With the opening of the war he was specially assigned to handle problems wherein the Bell System could be of assistance to the government in the national emergency. In this capacity he was, throughout the war, active on communication facilities for army camps, naval bases, supply depots and particularly for the government departments at Washington, where he also assisted the telephone company on general equipment and traffic engineering matters.

Shortly after the close of the war he became for a short time equipment and transmission engineer of the American Telephone and Telegraph Company; in 1920 was appointed plant engineer of that company, in which position he was concerned with all phases of the engineering of the telephone plant and with relations with other wire using companies. In December 1928 he was elected vice-president of Bell Telephone Laboratories, Inc., where he now directs operations involving more than 5,000 people engaged in development, research and related activities pertaining to the communication art.

Mr. Charlesworth became a Member of the Institute in 1922 and a Fellow in 1928. Also, he was a manager (1924-1927), chairman of the meetings and papers committee (1927-1929), and chairman of the New York Section (1929). In 1930 he became vice-president (representing District No. 3) and member of the board of directors. He has served on many Institute committees, being at present a member of the executive, coordination, Institute policies, finance, legislation affecting the engineering profession, technical program, and the Edison and Lamme Medal committees. He also is a representative of the Institute on the board of United Engineering Trustees, Inc.; a member of the National Research Council's division of engineering and industrial research, vice-chairman of the A.S.A. electrical standards committee, and a member of several other scientific organizations.

### J. Allen Johnson

Joseph Allen Johnson was born at Northboro, Mass., June 21, 1882, and received his early education in the schools of that town. He was graduated from the Worcester Polytechnic Institute with the degree of Bachelor of Science in electrical engineering in 1905.

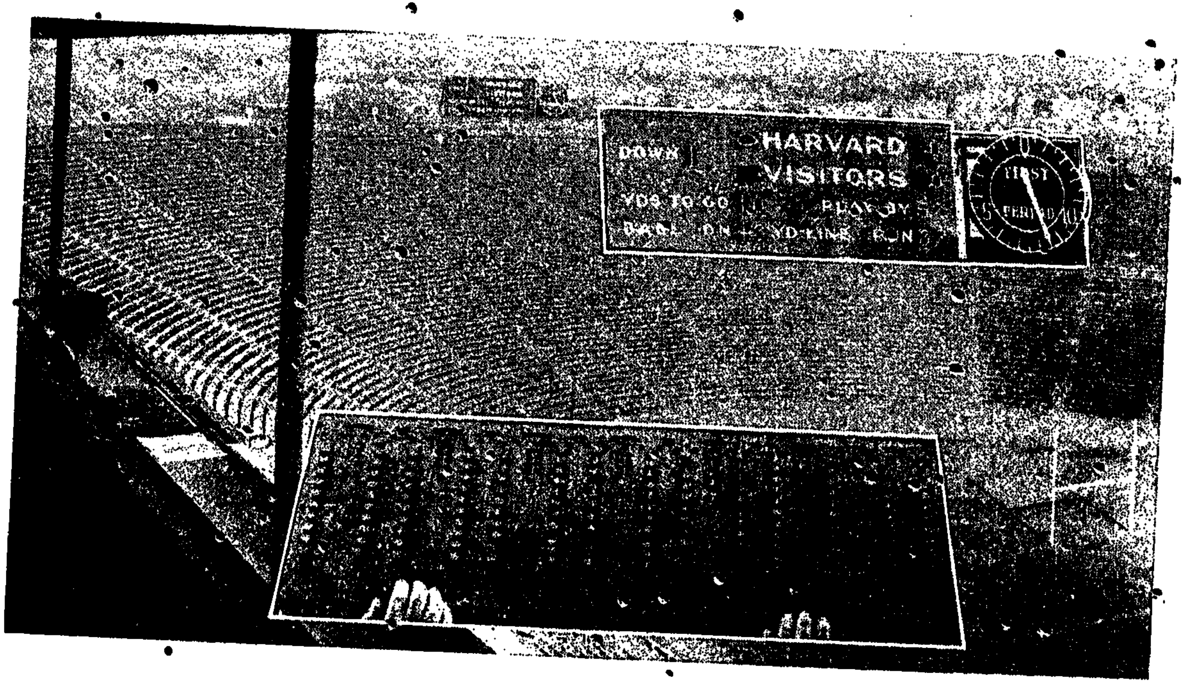
From 1905 to 1912, he was employed in electrical engineering work by the Ontario Power Company of Niagara Falls, being appointed electrical engineer of that company in 1912. In 1917 this company was purchased by the Hydroelectric Power Commission of Ontario, of which Mr. Johnson became assistant engineer, but still retained his other position. In 1918 he was appointed electrical engineer of the Cliff Electrical Distributing Company and Hydraulic Power Company of Niagara Falls, N. Y. and with the consolidation of these companies and the old Niagara Falls Power Company to form The Niagara Falls Power Company in 1918, he became electrical engineer of the enlarged company. In 1929 he was appointed chief electrical engineer of the Buffalo Niagara & Eastern Power Corporation, which position he now holds.

Mr. Johnson has contributed several important technical papers on such subjects as excitation and voltage control, reactors in hydroelectric stations, fire protection in a-c. generators, retardation method of loss determination. In 1926 he was awarded the "best paper" prize for District No. 1, for his paper "The Retardation Method of Loss Determination as Applied to the Large Niagara Generators."

He joined the Institute as an Associate in 1907, and was transferred to the grade of Fellow in December 1927. He has served as a member of the electrochemistry and electrometallurgy, electrical machinery, and protective devices committees. He became a director of the Institute in 1928 and served as chairman of the membership committee for the two years 1929-31. He was the organizer and first chairman of the Niagara Frontier Section and served in that

---

## A Scoreboard Visible Against Sunlight



This new electric scoreboard at Harvard's stadium, Cambridge, Mass., makes it possible for spectators to follow the ball, penalties, players, plays, and the score, with comparative ease. Moreover, the figures that flash across this new board are accurate and perfectly in time with the play itself, for the action of the board is controlled by a push-button station on the 50-yard line. The board, built by the General Electric Company, is 30 ft. long and 12 ft. high. The face is dull black and the ball and numeral indications are flashed to the spectators by groups of incandescent lamps so controlled that their brilliance varies with the amount of natural light over the field. Even with bright sunlight the numbers are clearly visible at 300 yd.

capacity from the date of its organization, February 10, 1925 to July 31, 1926.

He also is a member of the National Electric Light Association and the American Association for the Advancement of Science.

## E. B. Meyer

**Edward Barnard Meyer** was born October 22, 1882, at Newark, New Jersey. He received his technical education at the Newark Technical School, from which he was graduated in 1901, and at Pratt Institute, Brooklyn, New York, whence he graduated from the electrical engineering course in 1903.

That same year, Mr. Meyer entered the employ of Public Service Corporation of New Jersey as an engineering assistant and remained continuously with that organization and its subsidiary companies until 1922, holding successively the positions of field engineer (1906) in charge of the underground conduit and cable systems, assistant engineer (1909) supervising the preparation of special estimates and reports and of construction operations, and assistant chief engineer (1919). With the formation in 1922 of the Public Service Production Company he was appointed its chief engineer.

In 1929, Mr. Meyer was made a vice-president of Public Service Production Company, and in 1930, on the occasion of the merging of that company with United Engineers & Constructors Inc., he was appointed a vice-president of the latter corporation in the capacity of executive and engineering head of the Newark office.

Mr. Meyer became an Associate of the Institute in 1905, transferring in 1927 to the grade of Fellow. Active in Institute service, Mr. Meyer now is chairman of the following Institute committees: publication, award of Institute prizes, constitution and by-laws, Edison Medal, and the winter '32 convention; a member of the following committees: coordination of Institute activities, power generation, and representative for the Institute on the engineering societies monographs committee. Within recent years Mr. Meyer has been chairman of A.I.E.E. committees on meetings and papers (now technical program), transmission and distribution, finance, and executive committee of the New York Section; a member of the headquarters, Sections, membership, and several special and subcommittees. Also he was the Institute's representative on the U.S. national committee I.E.C.

Mr. Meyer's other technical activities have included active participation in N.E.L.A. and A.S.A. affairs, membership on the board of directors of the New York Electrical Society, Inc., membership in the Essex (County, N.J.) Electrical League, the U.S. Chamber of Commerce, the A.S.M.E., and the A.E.R.A. During the World War he served on important committees of the U.S. Army and Navy. His numerous contributions to the technical press have dealt chiefly with electric transmission and distribution problems and includes his book "Underground Transmission and Distribution."

## K. A. Auty

**Karl André Auty** was born in Yorkshire, England, of English parents and is now in his fifties. His education was pursued in Wheelwright Grammar School, *H.M.S. Conway* a British Naval Training Ship, and in the military class of a Paris university.

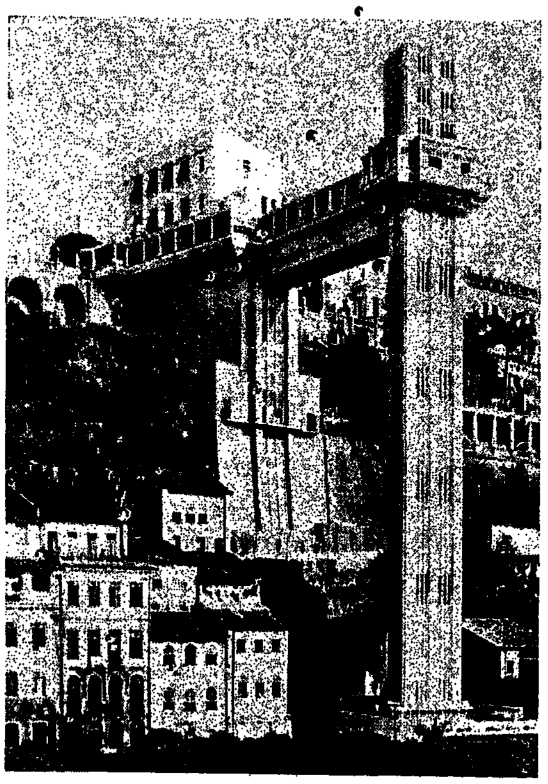
Family circumstances having changed, he took the engineering course at Victoria University, Nottingham. He then (1899) entered the Brush Electrical Engineering Company (England) as an engineering pupil for a three-year practical and theoretical engineering course.

Subsequently Mr. Auty came into charge of the Brush company's Lancashire district office, making a specialty of electrifying textile mills and old fashioned traction systems. In 1909 he became the illuminating and power engineer and headed the sales promotional department of the British Columbia Electric Railway Company in Vancouver, Canada. During the period of his affiliation with that company he was an active participant in the organization of the Vancouver Section of the Institute, and in the newly formed company Section of the N.E.L.A. Also he became a member of the Illuminating Engineering Society. Late in 1915 he joined the Commonwealth Edison Company of Chicago, Ill. as power sales engineer in the contract department. During the World War, he also assisted the State Council of Defense of Illinois. In 1917, he won the Insull medal for his paper "Advertising our K.W.H.'s."

Mr. Auty became an Associate of the Institute in 1912, and in 1917 was transferred to the grade of Member. He has been secretary, (1924-5), vice-chairman (1925-6), and chairman (1926-7) of the Chicago Section, and a member of the 1929 and 1930 national nominating committees. As an active member of the Western Society of Engineers (Chicago) he has served as chairman of its electrical section (1926-7), member of its board of management, and member of its Washington Award commission (1927-9). He is an Associate of the Association of Iron and Steel Electrical Engineers. He assisted in the original foundation of the Midwest Power Engineering Conference, and for the past four years has served as its treasurer. He is an earnest advocate and ardent promoter of amateur sports, and is serving as president of several amateur athletic organizations.

---

## Vertical Transportation



To CONNECT a bay front business district with a residential district 195 ft. above it, La Cerda Tower was placed in operation recently in Bahia, a coastal city in northern Brazil. The reinforced concrete tower is 240 ft. high and houses two large Otis express elevators reputed comparable with those used in the largest modern skyscrapers. On the day following its inauguration, more than 24,000 passengers were carried at 160 reis, a little less than two cents, per trip.

---

## G. A. Mills

**George Arthur Mills** was born July 5, 1885, in Buchanan County, Iowa. Pursuit of his early education carried him through the East Waterloo, Iowa, high school (1903) to the Iowa State College at Ames, whence he graduated in 1909 with the degree of Bachelor of Science in electrical engineering.

Subsequent to his graduation from college, he served an apprenticeship course with the Allis-Chalmers Manufacturing Company at its works in Cincinnati, Ohio. From that activity he went to Philadelphia where he served the University of Pennsylvania as instructor in electrical engineering (1910-11).

Leaving his educational pursuits, he became in succession: electrical engineer for the Waterloo, Cedar Falls and Northern Railway Company at Waterloo, Iowa, (1911-17); electrical engineer for the Winnipeg Electric Railway Company, Winnipeg, Canada (1917-19); general superintendent for the Wisconsin division of the Northern State Power Company, at Eau Claire, Wis. (1919-24); vice-president and general manager of the Kewanee Public Service Company, Kewanee, Ill. (1924-26); chief engineer of the Central and South West Utilities Company, and vice-president of the Pecos Valley Power & Light Company, both of Dallas, Texas (1926-to date).

Mr. Mills became a Member of the Institute in 1918, and was a charter member and first chairman of the Dallas Section of the Institute, which was formed June 2, 1928.

## C. R. Higson

**Charles Roy Higson** was born in Salt Lake City, Utah, August 29, 1893. After having completed his preliminary education in the grammar and high schools of Salt Lake City, he entered the University of Wisconsin, whence he graduated in 1907 with the degree of Bachelor of Science in engineering. In 1912 he was awarded the degree of Electrical Engineer.

During the period 1907-1908 Mr. Higson was with the General Electric Company, at Schenectady, in the test course. In 1909 he returned to the University of Wisconsin as instructor in electrical engineering, where he remained until 1912, when he entered the employ of the Utah Power and Light Company. He has been with that company continuously since then, holding the positions of engineering assistant (1913-18) assistant engineer (1918-25), and finally taking his present position of superintendent of distribution in 1925.

Mr. Higson became affiliated with the Institute in 1921, and has served as chairman of the Utah Section, and as chairman of the Pacific Coast convention committee (1926). He has taken a prominent part in engineering activities in Salt Lake City, and served in 1930 as president of the Engineering Council of Utah.

## G. A. Kositzky

**Gustav Adolph Kositzky** was born April 20, 1879, at Yankton, South Dakota. His early education was obtained in the Yankton and Niobrara (Neb.) public schools. Subsequently he spent four years at the University of Nebraska and then two years at Cornell University, graduating in 1905 with the degree of Mechanical Engineer in electrical engineering. He then entered the employ of the New York and New Jersey Telephone Company at Brooklyn, N. Y., in construction and engineering work. In 1907 he was promoted to construction engineer and during the following two years engineered the rebuilding of the outside distributing plant in that city. Following this, he was loaned (1910) to the Pacific Telephone and Telegraph Company in charge of plant engineering work covering the larger cities along the Pacific coast.

In 1911 he was transferred to the South Western Bell Telephone Company. From that date up to 1919 he filled the positions of plant engineer, general plant superintendent, and general engineer. In this latter position he was in charge of valuation work in connection with several large rate cases in Missouri, Kansas, and Texas.

In 1919 Mr. Kositzky was appointed chief engineer of the Central Union Telephone Company operating in Illinois, Indiana, and Ohio with headquarters in Chicago. In 1921 he became the chief engineer of the Ohio Bell Telephone Company with headquarters at Cleveland, the position he now occupies. For the next several years he directed the engineering work in connection with the unification of telephone service throughout Ohio which came about through the merging of the Bell and independent companies. This presented the largest engineering problem in connection with the unification of telephone service in telephone history.

Mr. Kositzky became a Member of the Institute in 1922 and was transferred to the grade of Fellow in 1929. During this period he has been active in Institute matters and has served as a member of various committees both local and national, the latest as chairman of the communication committee during the years 1929 and 1930. At present he is chairman of the Cleveland Section. Also he has served the Cleveland Engineering Society as trustee, vice-president, and president (1928). He is a past-president of the Nebraska Club of Cleveland; is a member of the Cleveland Chamber of Commerce and of several social and athletic clubs.

### A. H. Lovell

Alfred Henry Lovell was born in Hamilton, Ontario, Canada, July 13, 1884. His early education was obtained in the public schools of that city and in the Collegiate Institute at Niagara Falls. He received his degree of Bachelor of Science in electrical engineering from the University of Michigan in 1909 and his Master of Science degree from the same institution in 1914. He has had a varied experience in design and construction of power generation projects, having served on the engineering staffs of such organizations as the Ontario Power Company (1902-5), the Telluride Power Company (1906), the Rochester Railway & Light Company (1909-10), and the Gladwin Light & Power Company (1912). He has been on appraisal work with the Detroit Edison Company, the Mexia Power & Light Company, and others and on rehabilitation design of the Kansas City Railways plant. He was with Muralt & Company (1910-11), transmission line contractors for the Hydro-Electric Power Commission of Ontario.

During the war Professor Lovell served in the United States, England, and France as Colonel of Engineers with the 310th Engineers, (Michigan-Wisconsin) and later commanded the Third Engineer Training Regiment at Camp Humphreys, Va.

After serving since 1911 as an instructor he was appointed (1919) professor of electric power engineering at the University of Michigan, and in 1929 was appointed assistant dean of the College of Engineering, both of which positions he now holds. He is a member of Tau Beta Pi, Sigma Xi and Phi Kappa Phi. Professor Lovell has written for the Michigan Technic and is the author of a text "Generating Stations."

Professor Lovell became affiliated with the Institute in 1912 as an Associate, transferring to the grade of Member in 1913. He has served as secretary-treasurer, vice-chairman, and chairman of the Detroit-Ann Arbor Section, and now is a member of the Institute's committees on education and power generation. Also he is a member of the N.E.L.A. (Great Lakes Division) committees on overhead, and underground systems, and chairman of the committee on electrical engineering of the Society for the Promotion of Engineering Education.

### A. C. Stevens

Alexander Chilson Stevens was born in Riverhead, Long Island, N. Y., October 9, 1883. After early schooling in Middletown, Conn. and White Plains, N. Y., he spent two years at Wesleyan University and three at Cornell. He graduated from the latter in 1907 with the degree of Mechanical Engineer in electrical engineering. After graduation he taught for several years, first at Wesleyan as instructor in descriptive geometry and physics, and later as instructor in electrical engineering at Cornell.

In 1917 Mr. Stevens joined the staff of the transformer engineering department of the General Electric Company in Pittsfield, Mass. In 1925 his interest in educational matters resulted in his being placed in charge of the sale of apparatus to educational institutions for his company, with headquarters in Schenectady, New York.

Mr. Stevens has been actively interested in A.I.E.E. matters since joining as an Associate in 1918. At Pittsfield he was, for some years before moving to Schenectady, a member of the executive committee of the local Section; successively chairman of several of the important standing committees, secretary, and vice-chairman-elect.

When the North Eastern District of the Institute was organized in 1922, he was chosen by Vice-President G. Faccioli to serve as district secretary, a position he has held ever since. The experience gained in planning the pioneer regional meeting at Worcester, Mass., and other early district activities was of great help to the Institute in formulating a definite policy with regard to other districts. In 1930 he accompanied President Harold B. Smith on an extended trip to Institute Sections in the Middle Eastern, Southern, and South Western Districts, going as far south as Mexico City.

Mr. Stevens is a member of the Society for the Promotion of Engineering Education, the Cornell Club of New York, Eta Kappa Nu, Delta Kappa Epsilon, and several Masonic fraternal organizations.

## Engineers Condemn Bidding for Services

The practise of publicly soliciting bids from engineers and the responding to such invitations was condemned severely in the following resolution adopted some months ago by the American Society of Civil Engineers:

"Whereas, the Council of the American Institute of Consulting Engineers has been asked to give consideration to the practice, occasionally followed by certain public officials and some corporations, of soliciting from engineers bids for rendering engineering services; and

"Whereas, the Council is firmly of the opinion that, in the award of engagements for engineering services, the element of the price paid for such services is one of the least of several considerations which should receive weight in the determination of the award. Among those other considerations of the relative suitability of the several engineers under consideration for engagement are, their personal integrity and strength of character; their executive and administrative ability; the character, extent and variety of their professional experience; their general standing in the profession and before the public, etc., etc., and, lastly, the compensation expected; and

"Whereas, members of the engineering profession who respond to public invitations to submit bids for rendering engineering services, thereby:—

(a) Promulgate, encourage and dignify the above undesirable and objectionable practice;

(b) Lower their individual and professional reputation and standing; and

(c) Tend to bring indignity and discredit on an honorable profession, therefore,

"Resolved, that the Council of the American Institute of Consulting Engineers:

1. Strongly condemns the practice on the part of some public officials and corporations of publicly soliciting bids from engineers for the rendering of engineering professional services;

2. Expresses its strong disapproval on the part of engineers, and particularly on the part of Members of the American Institute of Consulting Engineers, of the practise of responding to such invitations to submit bids for their professional services;

3. Records its sincere belief that the above practices of extending and accepting invitations to submit bids for the rendering of engineering services are certainly not in keeping with the elements of professional character and dignity which should—and in large measure do—at present characterize and control the engineering profession, and which form most essential and important elements of the foundation on which the American Institute of Consulting Engineers is established."

Upon recommendation of the Institute's committee on code of principles of professional conduct, the board of directors of the Institute on December 4, 1931 adopted the following resolution:

Resolved, that the board of directors of the American Institute of Electrical Engineers hereby endorses in principle the resolution adopted by the American Institute of Consulting Engineers, June 4, 1930, condemning the practise of advertising for bids for engineering services, and

Resolved, further, that the board of directors urges members of the A.I.E.E. to oppose this practise, and to give their active support to suitable methods of emphasizing the importance of selecting engineers on the basis of their qualifications for the work under consideration.

## Report Submitted on Illumination Congress

The report of the United States national committee of the International Commission on Illumination for the year ending November 1931 has been submitted by the president, E. C. Crittenden (A'19-M'22). Representatives of the Institute on this permanent committee are: A. E. Kennelly (A'88-F'13-Life Member and past-president); C. O. Mailloux (A'84-F'12-Life Member and past-president); and C. H. Sharp (A'02-F'12). Following are excerpts from this report:

Among the activities of the committee the outstanding events of the year have of course been the session of the International Commission held at Cambridge, England, September 13-19, 1931 and the International Illumination Congress which preceded the commission sessions. . . .

Technical sessions of the congress were held in Glasgow, Edinburgh, Buxton (in connection with Sheffield) and Birmingham, England.

It is impracticable to summarize the proceedings of the congress and the commission in any brief statement. In both cases many parallel sessions were held; 23 technical meetings were scheduled for the congress; 22 specialized and 3 general sessions were listed for the commission, and in addition there were numerous committee meetings and special conferences. . . . Reports (of these sessions) were presented in October 1931 by Mr. G. H. Stickney (A'04-F'24) and other delegates at the Pittsburgh meeting of the Illuminating Engineering Society, and it is hoped that a composite report based upon these may be published so as to be generally available. The full report of proceedings of the congress will be a bulky document; it is understood that copies will be supplied gratis to those who registered as members, and will be available for purchase by others.

At the sessions more than 100 papers by individual authors were presented in addition to the committee reports prepared under the 18 secretariat projects which constitute the major activities of the commission. . . . Contributions from the United States included 9 individual papers and 4 secretariat committee reports.

As to the value of the results of such an international gathering, it is difficult to form a definite opinion. Undoubtedly the sessions with the publicity which accompanied them helped to create in Great Britain a general appreciation of the value of good lighting and of the artistic values of special lighting. . . . In the more technical fields, properties of materials and methods of measurement, undoubtedly the sessions helped to promote uniformity of practise facilitating interchange of data. Definite progress was made also toward unification of practise in aviation lighting and the dimensions of lamp bases and sockets, the latter being a project of the International Electrotechnical Commission with the I.C.I. invited to collaborate. . . .

The next plenary session of the commission is scheduled for 1934; an invitation from the German national committee to meet in Berlin was accepted. . . . With regard to plans for the 1934 session, the American delegates urged that effort be made to concentrate upon a limited number of subjects and to have those subjects treated in a manner adequate and appropriate for an international meeting. . . .

For the use of those who may wish to consult the papers presented before the proceedings are issued, complete files have been placed in the office of the Illuminating Engineering Society in New York City.

# Electricity in Modern Medicine Discussed Before New York Electrical Society

A MOST SUCCESSFUL meeting devoted to electricity in modern medicine was held by the New York Electrical Society, December 16, 1931, in the Engineering Auditorium, New York, N. Y. L.A. Coleman is president of this society and E.E. Dorting (A'13-M'22) is secretary. Dr. Howard Kelly, emeritus professor of gynecology at The Johns Hopkins University, Baltimore, Md., presided at the meeting and gave a short history of the subject.

The first speaker was Dr. G. Failla, physicist of the Memorial Hospital, New York, N. Y., who discussed "Physical Advances in the Treatment of Cancer by X-Rays." Doctor Failla described the method by which the cancer patient is exposed to x-ray radiation continuously 24 hr. a day for periods up to two weeks. The radiation is secured from a 900,000-volt Coolidge tube which for clinical work is operated at 700,000 volts with a current of 5 milliamperes. Under these conditions the tube can be operated continuously for several hours without trouble, and gives a radiation emission equivalent to that of 450 grams of radium costing more than $22,000,000. Various other X-ray tubes also are being used in the experiment. At present it is not possible to predict the outcome of this investigation. The important biological effects produced by these high voltage X-rays at any given point in the body are being evaluated, however, and it is hoped to determine conditions producing the best clinical effects.

## ARTIFICIAL FEVER

The second speaker, Dr. C. F. Tenney of the Fifth Avenue Hospital, New York, N. Y., discussed the use of short wave radiation in raising the internal temperature of a patient. The equipment producing this fever consists essentially of a short wave radio machine having two plates between which the patient is placed. The resistance of the body to the short wave passing between the plates produces a rise in temperature particularly in the liver, kidney, spleen, heart, and muscles, so that without harm to the patient, the body temperature can be elevated from 98.6 to 104 and 105 deg. fahr., in from 60 to 80 minutes. The fever produced is followed by a sweat without initial chill, and is much more comfortable than other methods of producing fever. It is hoped that the method will be of lasting benefit in the treatment of rheumatism and diseases of circulation.

Doctor Tenney then described a portable equipment used for the production of localized heating, such as in the knee, ankle, or other small portions of the body, without producing a complete fever. The heater consists of a vacuum-tube oscillator and a full wave rectifier which supplies the high voltage for the oscillator. The high frequency oscillator consists of two pliotrons operating at a frequency of from 10,000,000 to 14,000,000 cycles, the output of 200 watts being concentrated between two plates. The rectifier, an oil-immersed transformer having a 4,500-volt secondary and feeding two half-wave hot-cathode mercury-vapor tubes, furnishes the 2,000-volt d-c. supply for the oscillator. A rheostat is connected in the primary circuit of the high voltage transformer to provide plate voltage regulation.

The condenser plates are of thin aluminum, 10 in. in diameter, and are covered with hard rubber plates 12 in. in diameter to prevent arcing should the patient or attendant come in contact with them. In the field of undamped waves between the plates there is a rapid alternation with a 2,000-volt drop in potential. The greatest heating consistent with tube output has been obtained from the use of a 30-meter wave, oscillating 10,000,000 times per sec. between plates.

## ELECTROSURGERY

A summary of the history of high frequency currents in medicine was given by Dr. G.E. Ward of The Johns Hopkins Hospital, Baltimore, Md. and instructor of surgery, University of Maryland. The physics of high frequency currents was discussed with special attention to the biophysical changes wrought in living tissue by the passage of so-called medical diathermy and electrosurgical high frequency currents. Diathermy currents are those which raise the temperature of a part or the whole of the body within physiological limits, while electrosurgical currents raise the local temperature well above that which is destructive to the cells. This destruction with related factors makes possible the use of such current in the eradication of tumors and other diseased tissues. Further attention was given by Doctor Ward to electro-cutting which has come into vogue in recent years for the removal of diseased areas.

## THE ELECTROCARDIOGRAPH

The meeting was concluded with a discussion of the electrocardiograph by Dr. H. Williams, professor of physiology at Columbia University, New York, N. Y.

Doctor Williams told of the physical aspects of the electrocardiograph, and discussed the advantages of this equipment which is an important factor in the modern diagnosis of heart disease. The equipment makes use of the variation in electric current accompanying the contraction of the heart, and an instrument has been developed which is sufficiently sensitive and quick to follow the small and rapid changes in the movement of this organ.

## A.S.M.E. Holds Annual Meeting

Economics shared honors with engineering as a subject of major interest at the fifty-second annual meeting of The American Society of Mechanical Engineers, held in New York, N. Y., November 30 to December 4, 1931. While the registration, approximately 2,000, fell somewhat behind that of last year, there was no falling off of interest and significance nor in the broad extent of the program. Statistics indicate that there were scheduled some 25 technical sessions, 72 committee meetings, with 80 technical papers and reports presented, in addition to 6 special lectures and numerous other activities of a social and professional nature.

Regarding the election of officers for 1931-32 announcement was made as follows: *President,* C.N. Lauer; *vice-presidents,* R.M. Gates, C.M. Allen, F.H. Dorner, and W.B. Gregory; *managers,* A.J. Dickie, E.W. O'Brien, and H.R. Westcott; *delegates to American Engineering Council,* C.N. Lauer, Paul Doty (M'12), R.E. Flanders, C.E. Ferris, L.P. Alford, J.H. Lawrence (M'28), R.C. Marshall, Jr. (M'19), A.A. Potter, W.H. Trask, Jr. (A'12), and E.C. Hutchinson.

The sessions included many papers of undoubted value to electrical engineers, and it is hoped that space in future issues of ELECTRICAL ENGINEERING will permit the inclusion of a major portion of this information.

**Fellowship in Glass Founded.**—Announcement has been made of the establishment by the Macbeth-Evans Company of a fellowship in illuminating glassware at the Mellon Institute of Industrial Research, Pittsburgh, Pa. It is stated that the scientific investigations to be conducted will be a continuation along original lines and entirely independent of the technological research being carried on in the Macbeth laboratories. Dr. R.R. McGregor, a specialist in physical chemistry, has been appointed to the incumbency of this fellowship.

## Electricity to be Prominent in World's Fair

Extensive reservations for exhibit space in the electrical buildings of the 1933 World's Fair to be held in Chicago already have been contracted for by leading manufacturers of electrical equipment and supplies, producers of radios, and telephone and telegraph companies which provide the nation's principal communication facilities. The electrical group now is being erected on Northerly Island which adjoins the mainland at the fair site on Chicago's lake front; it is composed of three units: the electrical building, the communication building, and the radio building. (See ELECTRICAL ENGINEERING, V. 50, p. 762, Sept. 1931.)

Space on the first floor of the electrical building will be devoted to demonstrations of manufacturing processes; the second floor has been reserved for displays depicting the development of electrical engineering and electrical illumination. Connecting with the electrical building on the north is the communications building, all space in which already has been contracted for by leading telephone and telegraph companies; their exhibits will tell stories of the discovery, invention, and perfection of modern wire communication. At the extreme northern end of the group is the radio building. Exhibits already planned for this section will demonstrate how radio branched off from two-way communication and became the marvelous news and entertainment feature which it now is. In this building also it is expected to stage a broadcast sponsored by the two leading radio chains to demonstrate how programs of news, entertainment, and music are "put on the air."

In addition to the many attractive displays, stories of the epochal discoveries and inventions made in the field of electricity during the past hundred years will be told by men of vision and genius who are worthy successors to those who discovered and developed electric power. Thus in its entirety the electrical show is expected to be one of the most popular and spectacular features of the whole "Century of Progress" exposition.

**Engineering Studies Open to Unemployed.** Announcement is made by Dean J. W. Baker that classes in the engineering school of Columbia University have been opened to unemployed professional engineers. President Nicholas Murray Butler has sanctioned the measure after the proposal had been advanced by the professional engineers' committee on

## Hoover Dam Tunnels Near Completion

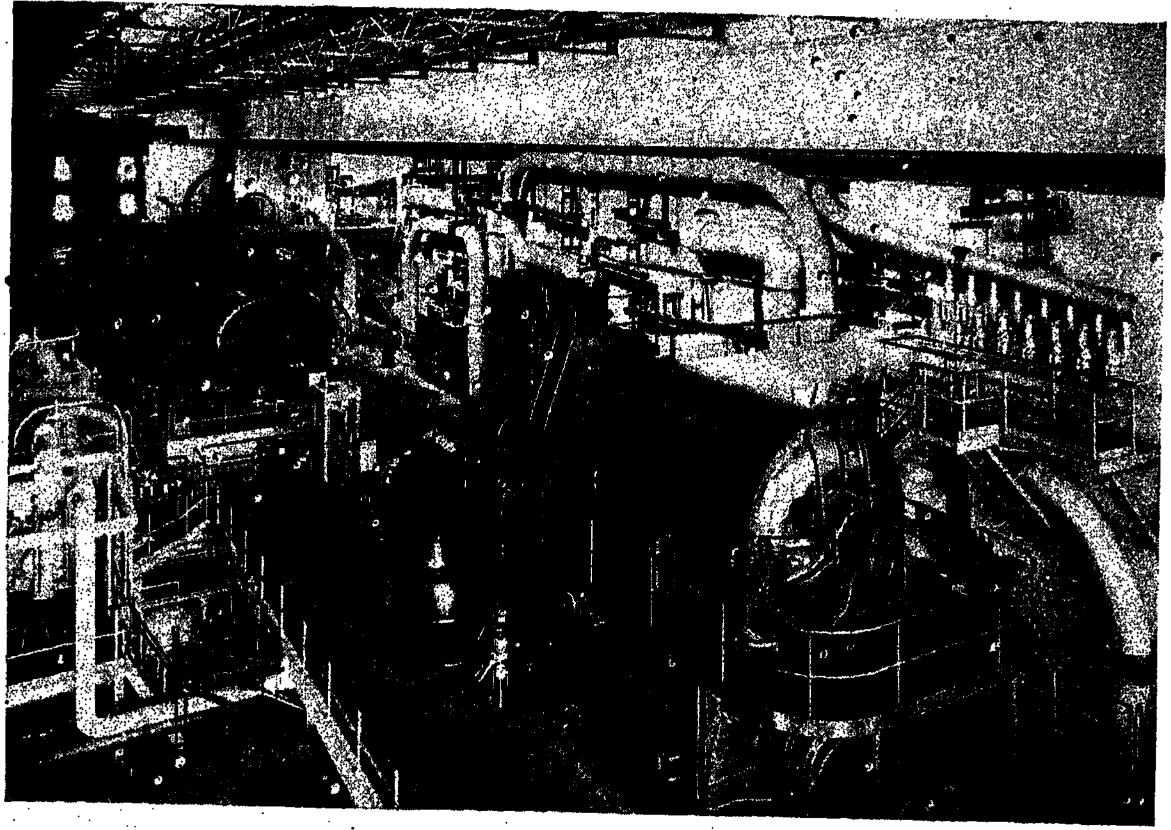
U.S. Bureau of Reclamation Photo

BEFORE excavation can be started on the foundation for Hoover Dam, four diversion tunnels each 4,000 ft. long must be completed. These tunnels (56 ft. diameter inside of rock, 3 ft. concrete lining) will divert the stream flow around the dam site. Downstream portals are shown above. The attack on these tunnels is from both upstream and downstream portals and from two additional faces in each tunnel opened by adits driven in from the canyon wall at about midpoint. More than 14,000 ft. of top heading has been completed, the two inner tunnels being holed through.

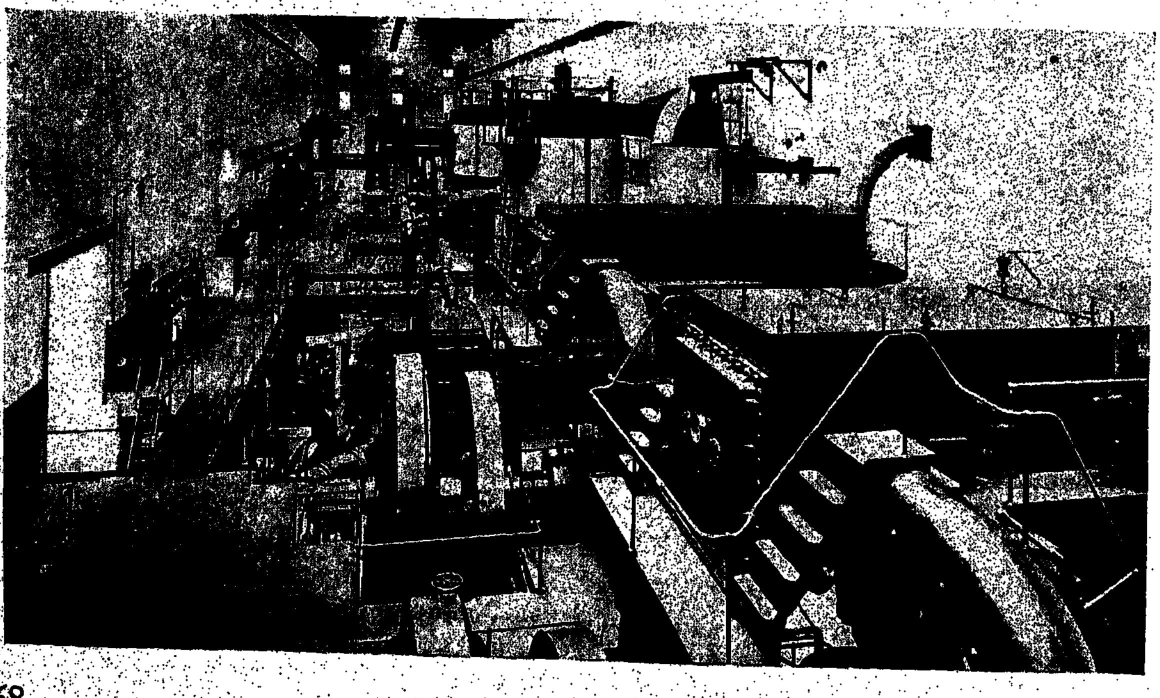
unemployment. Applicants must secure a certificate from the engineers' committee, showing that they are accredited members of the profession and are idle through no fault of their own. The number admitted will be limited by the size of the lecture halls only. By this means it is hoped to preserve morale during a period of enforced idleness, and to broaden the applicant's knowledge of engineering.

---

## 100,000 Kw. in Space Designed for 6,500



THE FIRST steam plant in the western states utilizing a boiler pressure of 1,400 lb. is station "A" of the Pacific Gas and Electric Company. The engine room of this plant, located in the center of the San Francisco industrial area, has had an interesting evolution. As constructed in 1901, it is 425 ft. long and 57 ft. wide; the original plant contained six vertical compound steam engines operating under 200-lb. pressure, and driving electric generators. By 1910 this equipment had been replaced by ten vertical reciprocating oil engines driving 1,500-kw. generators; by 1919, four 12,000-kw. turbo-generator units had replaced all but two of these engines, giving a plant capacity of 57,000 kw. This latter equipment, illustrated below, remained essentially intact until the most recent and perhaps the most striking change was made, when the two 50,000-kw. turbo-generator units shown above replaced two of the older turbo-generator units and two of the engine driven units. The same floor space required for 6,500 kw. in 1902 now contains equipment rated 100,000 kw. The steeple-compound units with the high-pressure turbine directly over the low-pressure one have not required even an increase in headroom.



## American Institute of Physics Organized

Formal announcement has been made of the organization of the American Institute of Physics established by the American Physical Society, the Optical Society of America, the Acoustical Society of America, and the Society of Rheology. The new institute will serve the four societies mentioned, and through them, physics in general in matters of common interest, particularly in their relation to other societies and to the public. The board of management consists of Karl T. Compton, chairman, and G. B. Pegram, secretary. H. A. Barton is director, and J. T. Tate, advisor on publications.

The membership of the four societies establishing this institute includes a majority of the active physicists in the country, whether interested in pure or applied physics and whether filling university or industrial positions. This large group has felt first the need for unification of effort, and second for the existence of an agency which would perfect details of organization and co-operative publication of physics journals; also to assist the newspapers to disseminate accurate news of important developments and applications of physics. The value of these aims is obvious and it is also obvious that they do not conflict with the aims of any already constituted agency. It is indeed to be expected that those agencies of service to science already operating will find their scope and activities increased through the work of this institute.

## "E.E." Offers Index and Binding Service

The annual index covering the contents of ELECTRICAL ENGINEERING for the twelve issues of the calendar year 1931 will be available for distribution after January 15, 1932. It is to be published in a form convenient for those wishing to file it for reference or to include it in bound volumes of the 1931 monthly issues. A notice of this index appeared in the advertising section of ELECTRICAL ENGINEERING for December 1931 and is repeated in this issue. An order form may be found on p. 992 of the December issue. The index will be printed in a quantity governed by the number of requests received prior to January 15, 1932.

The advertising pages for December 1931 included also the notice that binding service for the 1931 copies of ELECTRICAL

ENGINEERING now was available at cost. Upon shipment of the copies to the order department of the Institute, they will be bound neatly and durably, and returned prepaid. Full details are given in the advertising section of this issue and an order form appears on p. 70.

## Consulting Engineers Denounce Free Engineering

The American Institute of Consulting Engineers, at the October meeting of its council, accepted a report of its committee on professional practise and ethics protesting against the furnishing of engineering plans and specifications by manufacturers and distributors of equipment and materials. The committee reported:

"The attention of the council of the American Institute of Consulting Engineers periodically has been called to the practise, on the part of large manufacturers and distributors of equipment and materials, of making investigations, engineering plans, and specifications for architects and owners, involving the use of equipment and materials which they sell, all apparently without charge or for a nominal charge.

"On at least two specific occasions the attention of the officials of several of the largest manufacturing concerns has been called to such practise without any apparent lasting results.

"The field of the professional engineer, engaged in private practise, constantly is being invaded by manufacturing concerns, both large and small, through the medium of offering to the prospective purchasers of their products of manufacture free consulting engineering service.

"It is clearly evident that such offering is made for the single purpose of selling their particular articles of manufacture, thus restricting the purchaser to products which may or may not be standard and of the best quality. It is equally evident that such practise not only is vicious, from the standpoint of the engineer engaged in private practise, but deprives the purchaser of the judgment of an impartial expert whose only interest is the interest of his client."

The committee therefore offered the following resolutions and recommended their adoption by the I.C.E.:

"RESOLVED, that the American Institute of Consulting Engineers denounces the practise of designing and planning of engineering work by those who have interests other than the efficiency and effectiveness of the installation, as *highly unethical*, and

BE IT FURTHER RESOLVED, that the Institute (I.C.E.) use such means as its council and/or officers deem best to eliminate such unethical purposes."

Copies of the report and notices of the action taken have been sent to the presidents of several corporations throughout the United States.

# Letters to the Editor

## Progress is the Way Out of Depression

*To the Editor:*

Mr. Berresford's article "Progress is the Way Out of Depression" in the December 1931 ELECTRICAL ENGINEERING is good promotion talk and has an excellent sales appeal in tending to make each human being think that he accomplishes more than the foremost leader. It may be exactly the kind of talk we should have at the present hour; I have been following his advice for the past year. Yet his primary thesis appears to be in conflict with many an article that I have read in the last ten or twenty years and also with my own observation.

The first part of the fourth paragraph, for example, seems to conflict with fundamental facts, although it may agree with superficial ones. Many of us think that the daily effort of the millions, when it is good, comes from the effort of the outstanding few and only from that source; we think this in spite of the essential failure of the church to provide adequate leadership, because there are successful leaders even among those who do not profess to be leaders. History indicates that without the thinking and the leadership of a few, man has tended to revert rather than to advance, which is largely why we are honoring Faraday this year.

"Do your bit as best you can" is good advice now and always will be, except for perverts, but all men are created equal only before the law. Without true leadership man has retrogressed in the past and will presumably continue to do so in the future. Hence in reading Mr. Berresford's article it will perhaps be well to keep in mind the possibility that, in trying to drive home his worthy point, he may have overstepped the bounds of fact. The end may at times justify the means, unless the means manufactures a boomerang.

Very truly yours,
H. H. KETCHAM (A'13-M'23 and Life Member) (Technical Editor, Forest Products Lab., Madison, Wis.)

## Characteristics of Arc Welding Generators

*To the Editor:*

I acknowledge receipt of the paper by Mr. J. H. Blankenbuehler on "An Improved Arc Welding Generator." An article based upon this paper was published in ELECTRICAL ENGINEERING, August 1931, p. 666-8. The information contained therein is especially interesting to me as ten years ago I took a patent—No. 1,549,874—on the use of d-c. transformer in the welding and excitation self-circuits of any single-operator inherently—regulating arc welding generator.

The article explained many things to me that I did not understand before. However, my comments on his paper are that the statements regarding porosity being bettered by the welding machine and that freezing of the electrode is lessened by stopping the inrush of current are not agreed with by those people experienced in welding and are very misleading to others.

Freezing of the electrode is a phenomenon that is of no concern in welding because a good welder never freezes. Freezing or sticking is the earmark of an inexperienced or beginner welder. What is of some importance, however, is heating up the cold work as quickly as possible so the start of the weld is as well fused as the remainder. Welding, at present, is a compromise between too cold a start and too hot a finish. Porosity is caused by the latter—too hot a finish, and cold shots are caused by the former. It is very important to have the momentary rush at the starting as great as possible. Often a larger size sheet is used to effect this purpose. Sometimes tapered rods are used to offset this difference which obtains either in automatic or manual welding because all the heat that is in the arc, electrode or work, in the next instant is deposited in the work, which becomes hotter and hotter. Good welding consists of a compromise between how hot you can start without finishing so hot as to burn the metal, and judicious welding with invariably short lengths of electrodes have given the best results to date.

Furthermore, the curbing of the transient; that is, holding it below 200 per cent holds down the welding persistency. In other words, in chasing after this mechanical freezing of the electrode, the welding qualities are lessened. In other words, if you teach the machine to react quickly and then deliberately curb it, naturally both the properties of biting quick and holding back cannot be present under all conditions. You might be able to teach a dog to bite some people and not bite others but with a welding machine, I think it is quite impossible. So far, no one has discovered how to describe in technical terms this persistency of the arc but the difference between a machine that is curbed at 200 per cent and one that is allowed to react naturally with a time recovery of 2/10 of a second or less is the difference between Bobbie Jones or me or you.

Very truly yours,
O. J. HOLSLAG (M'19)
(President, Electric Arc Cutting & Welding Co., 152 Jelliff Avenue, Newark, N. J.)

## Has Man Benefited by Engineering Progress?

*To the Editor:*

The published introduction to the Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?" very definitely emphasizes the "deeper effects" of engineering achievement and its spiritual consequences. Mr. Mees' thought provoking article and letters of comment by Messrs. Dreher and Johnson are stimulating contributions to the announced topic. The apparent straying or lack of definiteness in some of the subsequent articles is disappointing. Too much responsibility is thrown upon the reader to deduce the author's viewpoint on the larger questions at issue.

Mr. Insull, conceding a disadvantage to humanity due to the congestion of industry in the past, predicts an improvement in the future because of the widespread distribution of power. In stating these well known facts about power supply and distribution, the author seems to imply that on the whole man has not benefited in a broad way in the era just opening, for the reasons stated. On the other hand, we may do the author an injustice. Perhaps he intends to imply all has been well and satisfactory as a result of engineering developments in the past except the slight congestion of industry, and that little matter is well on the road to being corrected. A more definite commitment on the fundamental issues would have been welcome.

Mr. Grunsky emphasizes two principal points. First, a plea for the establishment of museums, art galleries, music conservatories, etc., as a stimulus for the spiritual uplift of the people. Second, a suggestion that these public improvements should be financed by new high rates of taxation, not, however, by the "prevailing unfair" system. As regards taxation, a great number of diverse theories have been proposed and many tried and discarded. Although engineers are (or should be) vitally interested in this topic, taxation has no more direct bearing on engineering progress and its effects than religion has. It is quite true, however, that not only taxation but religion and other institutions of our complex social order have an important effect on human welfare and happiness.

As regards the establishment of additional structures for spiritual uplift and public welfare, there are those who believe that not more edifices, but a more general acquaintance with the interiors of some already built (*e. g.*, places for worship) would better serve the purpose. However, this is beside the point. The responsibility of engineering developments is in no clear way indicated or even remotely suggested. The paper, indeed, is an excellent plea for the expansion of the fine arts as a basis for the spiritual uplift of the people. With this thesis the critic takes no exception, but manifestly the implied conclusion is, increase the number of artists, musicians, etc., but not the engineers. If the author had this conclusion in mind it would have been more satisfactory had he directly stated it. If he did not have this or a similar idea it is a little difficult to understand just how the paper fits into the symposium.

If the sponsors of these articles desire a general discussion of the fine arts, of religion, of psychology, of economics, of politics, etc., as well as of engineering progress, all of which have a direct bearing on happiness, there can be unlimited ramifications with but little coherence.

Yours very truly,

L. H. RITTENHOUSE (A'10)
(Professor of Engineering,
Haverford College, Haverford, Pa.)

## Nerve Injuries from Electric Shock

*To the Editor:*

The very interesting work done by W. B. Kouwenhoven and O. R. Langworthy as reported in the December 1931 issue of ELECTRICAL ENGINEERING takes into account the effects of direct-current and low-frequency alternating-current.

The undersigned has observed that theories on "electric shock" are gradually shifting from the purely physiological viewpoint to a more biological and physical one. It seems to him that the primary causes of injury are of either electrolytic or thermic nature, and physiological effects are the result of heating or electrochemical decomposition of cell contents. A strong support for this thought lies in the fact that high-frequency currents injure the living body only through heating.

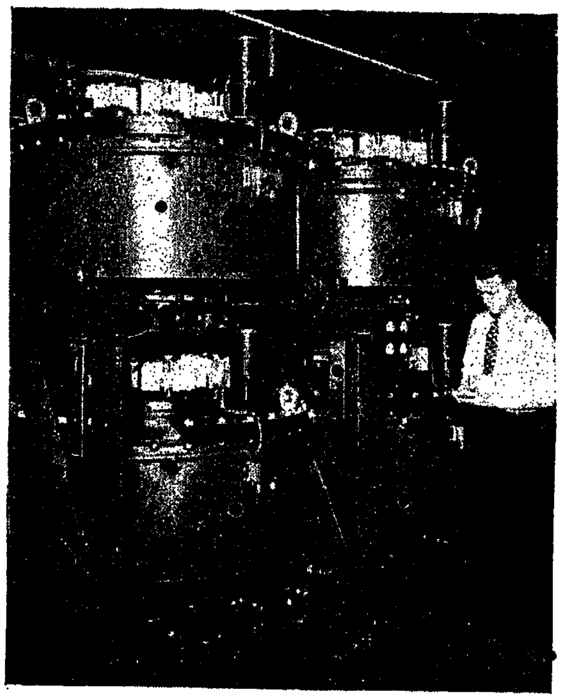
Lack of facilities so far prevented the writer from proving his theory experimentally. He believes that a continuation of the photomicrographic studies at The Johns Hopkins University with currents of higher frequencies will produce further interesting and valuable results.

Very truly yours,

KURT MAHNKE (A'26)
(401 Avenue D, Forest Hills,
Pittsburgh, Pa.)

## Mercury Arc Rectifiers of Sectional Construction

As the size of mercury arc rectifiers is increased, difficulties of design to secure satisfactory operation also increase greatly. Large units tend to be not only less reliable but actually less efficient than the smaller ones. To overcome these difficulties, there have been developed sectional rectifiers of the size which gives the best performance and so shaped that they may be placed together to form compact assemblies of any rating.



Westinghouse E. & M. Co. Photo

3,000-kw. rectifier made up of four 750-kw. sections

The 3,000-kw. rectifier unit illustrated consists of four interchangeable 750-kw. sections integrally mounted, fed from a single transformer, and easily withdrawn on rollers after the fashion of truck type switchgear. For this rating, the use of these sectional units results in a rectifier, each section of which is not only more reliable, but one in which a failure of one section does not involve complete shutdown of the entire group. Spare units may be provided easily. Piping and wiring are simplified, and both energy losses and space required are reduced by about one-third.

**American Scientific Congress Postponed.** Through the Pan American Union, word has been received from the Mexican Government announcing the postponement until November 1933 of the sessions of the Seventh American Scientific Congress, which was to have been held in Mexico City February 5-19, 1932. It was found that present world conditions make it impossible for many nations to send special representatives.

## Test Code for Transformers now Available

Pursuant to notice which appeared in the October issue of ELECTRICAL ENGINEERING (p. 844) giving publicity to effort on the part of the Institute's standards committee to develop test codes for electrical machinery and apparatus, this committee now has formulated a preliminary report on the proposed "Test Code for Transformers," pamphlet copies of which may be obtained without charge from A.I.E.E. headquarters, 33 West 39th Street, New York, N. Y.

# American Engineering Council

## N.J. Engineers Promote Public Works for Relief

A statewide plan of municipal improvement is sponsored by a New Jersey employment committee of the A.E.C. which has just been organized with Lynne J. Bevan of Montclair as chairman. The aid of the 2,800 licensed engineers and land surveyors in the state will be enlisted in shaping public works programs in every community.

These programs will be adjusted to a state plan, the legislature having provided that the state, to the limit of allotments, may meet dollar for dollar the money paid by local political units for labor or personal services. Tasks ranging from city planning studies to road and street repairs and the remodeling of public and semi-public buildings are suggested; elimination of grade crossings, widening and beautifying of streets, plans and estimates for future highways and parks are other objectives.

The members of the committee include: Governor Morgan F. Larson; Harvey N. Davis, president of Stevens Institute of Technology, Jersey City; L. P. Alford, Montclair, vice-president of The Ronald Press (N. Y.); Lincoln Bush, East Orange, past-president of the American Society of Civil Engineers; Dean P. H. Daggett (A'08) Rutgers University, New Brunswick; Charles A. Mead, chief engineer of the division of bridges and grade crossings of the New Jersey Public Utilities Commission; E. B. Meyer (F'27), Newark, vice-president, United Engineers and Constructors, Inc.

The committee also will work with the professional engineers unemployment relief committee organized in New York by the four Founder engineering societies to aid idle engineers throughout the whole New York metropolitan area. A New Jersey section of the latter committee has been formed with Louis A. Janny of the American Institute of Mining and Metallurgical Engineers as chairman.

The engineers, according to Chairman Bevan, purpose to stimulate legitimate construction work, and to avoid unsound projects. "The immediate objective upon which your action is requested," he said in an appeal to the engineers and surveyors, "is the bringing to light of sufficient necessary public project work in your vicinity, and the incorporation thereof in the official plan of your community which must be filed with the state director of emergency relief by December 1, 1931."

# Personal

## Edwin W. Rice, Jr. Awarded Edison Medal

Dr. Edwin Wilbur Rice, Jr., has been awarded the A.I.E.E. Edison Medal for 1931 "for his contributions to the development of electrical systems and apparatus and his encouragement of scientific research in industry." The Edison Medal was founded by associates and friends of Thomas A. Edison, and is awarded annually for "meritorious achievement in electrical science, electrical engineering, or the electrical arts" by a committee consisting of 24 Institute members.

Doctor Rice is one of the pioneers of electrical development in the United States and has played a conspicuous part, in association with the late Charles A. Coffin, in the building of the present General Electric Company. As a schoolboy in Philadelphia he came in contact in 1876 with Prof. Elihu Thomson, then a young teacher in the Boys' Central High School. When in 1880 the professor gave up teaching to go into electrical manufacturing as scientist and inventor, young Rice gladly accepted an opportunity to become his assistant. He went with Thomson to New Britain, Conn., in the old American Electric Company, and in 1883 went with the professor to Lynn, Mass., upon the organization of the Thomson-Houston Electric Company. At the age of 22 he was made plant superintendent and had this full responsibility until the consolidation of the Thomson-Houston Electric Company and the Edison General Electric Company in 1892, under the name of General Electric Company.

In the new company Doctor Rice first was made technical director, then vice-president in charge of manufacturing and engineering. Eventually he became senior vice-president and, in 1913, he succeeded Mr. Coffin as president of the company. In 1922, after nine years' service in that office, he was succeeded by Gerard Swope. Doctor Rice at that time was made honorary chairman of the board, which position he still holds. He has contributed much through organization methods, improved factory routine, technical development, and engineering and scientific inventions to the prominence attained by the General Electric Company. His degrees are: Honorary A.M., Harvard (1903); Sc.D., Union University (1906); Doctor of Engineering, Rensselaer Polytechnic (1917); Sc.D., University of Pennsylvania (1924).

E. W. RICE, Jr.

He is a past-president and Fellow of the Institute, and a Chevalier Legion d'Honoeur of France. In 1917 he was decorated by the emperor of Japan with the Third Order of the Rising Sun with Cordon. He invented the present fundamental form of high-voltage oil switch and the cellular system of separating buses and circuits; as well as the application of synchronous converters to the building of unified a-c. and d-c. distribution systems. He was responsible for the adoption by his company of the Curtis steam turbine, and for the establishment of the company's research laboratory. He has endorsed and promoted many modern forms of industrial organization and of methods of advancing employees' welfare.

As a recipient of the Edison Medal, Doctor Rice shares the honor with: Elihu Thomson, Frank J. Sprague, George Westinghouse, William Stanley, Charles F. Brush, Alexander Graham Bell, Nikola Tesla, John J. Carty, Benjamin G. Lamme, W. L. R. Emmet, Michael I. Pupin, Cummings C. Chesney, Robert A. Millikan, John W. Lieb, John White Howell, Harris J. Ryan, William D. Coolidge, Frank B. Jewett, Charles F. Scott, and Frank Conrad.

A. B. Campbell (A'19) after thirteen years of service with the General Electric Company's Fort Wayne (Ind.) plant, where he was intimately connected with various developments of demand meters, thermal relays, timing devices, and allied equipment for the meter and fractional horsepower motor departments, is now chief engineer for the Seth Thomas Clock Company, Thomaston, Conn. While in Fort Wayne, Mr. Campbell served the A.I.E.E. as both secretary and chairman of its Fort Wayne Section.

Bancroft Gherardi (F'12) was reelected president (1932) of the American Standards Association at its annual meeting held in New York City December 9, 1931. Mr. Gherardi is vice-president and chief engineer of the American Telephone & Telegraph Company (N. Y.); active in Institute affairs, he has served prominently as president (1927-8) vice-president (1908-10) and manager (1905-8 and 1914-17).

G. N. Brown (M'21) who formerly was associated with the New York office of the Ohio Brass Company, sales department, now has joined the commercial staff at N.E.L.A. headquarters, as manager of its electric refrigeration bureau. Mr. Brown's service with the Ohio Brass Company extended over a period of four years as district manager, first of the Philadelphia office, and then of the New York office.

J. C. Parker (F'12) was reelected December 9, 1931, at the annual meeting of the American Standards Association to serve (1932) as vice-chairman of the Standards Council. Mr. Parker is vice-president in charge of engineering for the Brooklyn (N. Y.) Edison Company; he has served the Institute in several capacities including that of vice-president (1921-2).

J. A. Foley (A'31) from 1923 to 1930 in the engineering design, application, and sales departments of the General Electric Company in both Cleveland and Toledo, Ohio, in the latter location serving also as engineering consultant over a period of approximately two years, recently became an electrical engineer of the Worthington Pump and Machinery Corporation in Chicago, Illinois.

P. J. Wilson (M'12) formerly sales manager of the Narragansett Electric Company, Providence, R. I., recently resigned to become vice-president and treasurer of the New England Branch of Kaslin & Company, Inc., with main offices in Syracuse, N. Y. Mr. Wilson's headquarters, however, will be in Providence.

K. W. Johansson (M'28) formerly serving the Westinghouse Electric and Manufacturing Company as an electrical engineer at the East Pittsburgh plant, now is special representative covering oil fields and other industries in Venezuela, Columbia and other South American countries for the Westinghouse Electric International Company.

R. S. Eininger, Jr. (A'29) who has been serving the General Electric Company, Erie, Pa., as cost engineer now has joined the company's force at Pittsfield, Mass., in the manufacturing general department. Mr. Eininger was student secretary of the Drexel Branch during the year 1926-27.

Clyde Treon (A'28) for some time past distribution superintendent of the Pernambuco Tramways & Power Company, Pernambuco, Brazil, South America, has returned to the United States and is serving now in like capacity with the West Penn Power Company, Pittsburgh, Pa.

Fraser Jeffrey (F'24) electrical engineer with the Allis-Chalmers Manufacturing Company, West Allis, Wis., recently was elected vice-president of the Engineers' Society of Milwaukee, of which he has been a member since 1907 when he started his career in the electrical industry.

J. C. Van Horn (M'28) has been made a vice-president of the R.C.A. Institutes, Inc., Philadelphia, Pa., and will have charge of resident schools at Philadelphia, New York, Chicago, and Boston. Mr. Van Horn has been serving the R.C.A. Institutes as general superintendent.

Winthrop Allen (A'30) has changed his work as assistant electrical engineer of E. I. duPont de Nemours Company, Wilmington, Del., to associate himself with the Prudential Insurance Company, Newark, New Jersey, as electrical engineer of home office buildings.

Paul S. Clapp (A'18) until recently managing director of the National Electric Light Association, New York, N. Y., resigned from that office to become vice-president of the Columbia Gas and Electric Corporation, with offices at its headquarters in New York City.

E. G. Waters (A'90) who has completed a record of more than 42 years of continuous service with the General Electric Company, and for the past 25 years has been secretary of its sales committee at Schenectady, N. Y., now at his own request has been retired.

E. J. Verrier (A'28) recently serving as electrical engineer of the Engineering Equipment Company, Montreal, Can., now has been made power plant superintendent for the Anglo Newfoundland Development Company, Grand Falls, Newfoundland.

S. R. Barrett (A'28) who in the past has been associated with the Hemenway Electric Corporation, Springfield, Vermont, now is station operator for the Turners Falls Power and Electric Company, Gobble Mountain Station, Westfield, Mass.

C. H. Willis (M'28) who since 1926 has been assistant professor of electrical engineering, Princeton University, Princeton, N. J., now has become associate professor in the electrical engineering department of the university.

B. S. Anderson (A'30) manager of the Japan branch of the English Electric Company, Ltd., at Tokyo, now has been transferred to Shanghai, China, where his address will be in care of Jardine Engineering Corporation, Ltd.

J. T. Serduke (A'30) until recently a research engineer at the General Electric Company's laboratory, Schenectady, N. Y., has joined the department of physics, Massachusetts Institute of Technology, Cambridge, Mass.

T. R. Cook (M'16) who has been engineer of Coverdale and Colpitts, consulting engineers, New York City, recently was made service manager of the Baldwin Locomotive Works' Paschall station, Philadelphia, Pa.

Emerick Toth (A'29) formerly laboratory assistant, Kolster Radio Corporation, Newark, N. J. recently became receiver engineer of high frequency circuits for Wired Radio, Incorporated, Ampere, N. J.

Herbert Southworth (A'22) formerly merchandise manager for the Fall River Electric Lighting Company, Fall River, Mass., now is assistant manager of the North Adams Gas Light Company, North Adams, Mass.

G. G. Post (A'11) vice-president and chief electrical engineer of the Milwaukee Electric Railway & Light Company, Milwaukee, Wis., recently was elected a director of the Engineers' Society of Milwaukee.

H. A. Luedeke (A'29) has joined the National Broadcasting Company, New York, N. Y., as monitoring engineer. His previous work was with the Western Electric Company, at Kearny, N. J., as design engineer.

M. B. Karelitz (A'27) who has been an engineer at the Westinghouse Electric and Manufacturing Company's main plant, East Pittsburgh, Pa., now has been transferred to the company's East Springfield works.

John Egli (M'26) who has been manager of service and erection for the American Brown Bovari Electric Corporation, now is with the Allis Chalmers Manufacturing Company, Milwaukee, Wis.

M. G. Lord (A'22) who since 1907 has been in the ranks of companies affiliated with the Southern Colorado Power Company, Pueblo, Colo., now is vice-president in charge of operation for that company.

O. B. Parker (A'29) for the past four and a half years assistant chief engineer of the Pacent Electric Company, Inc., New York, N. Y., has been promoted to the position of chief engineer.

J. W. West (M'28) who has been manager of production for the R.C.A-Victor Corporation at Camden, N. J. now has joined Frozen Confections, Incorporated, Maplewood, N. J.

H. P. Currin, (M'30) electrical engineer of the Eugene water board, Eugene, Ore., now has been appointed electrical engineer of the State board of engineering examiners of Oregon.

H. A. Faesi (A'27) serving in the past as an electrical engineer, for Allied Engineers, Incorporated, Atlanta, Ga., now has joined the Georgia Power Company in that city.

## Obituary

Howard Rankin Sargent (A'96-M'12 and Member for Life) engineer of the merchandise department of the General Electric Company, Bridgeport, Conn., died suddenly at his home in that city, December 8, 1931. The relapse followed an operation for appendicitis. Mr. Sargent was sixty years of age and a native of Newton, Mass. He was graduated from Massachusetts Institute of Technology in 1893, and promptly thereafter entered the employ of the old Thomson-Houston Company at Lynn, Mass. There he remained, with the exception of an interval during which he was working at Marlboro, Mass., until in 1894 many of the Lynn engineers were transferred to Schenectady. When the merchandise department of the company was organized in 1922, Mr. Sargent was transferred to Bridgeport as manager of the wiring supplies engineering division. In 1926 he was made engineer of the merchandise department. In the course of his professional career, Mr. Sargent has been credited with many important electrical inventions. He also was active in the National Electric Light Association and the National Electric Manufacturers Association.

Joseph Walter Miles (A'02) for many years in charge of foreign engineering for the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., and recently appointed consulting engineer to the foreign and development information bureau, died suddenly November 28, 1931. Mr. Miles had been a member of the Westinghouse organization for thirty-seven years, and lacked only six years' membership to qualify as a Member for Life of the Institute. He was still a resident of Irwin, Pa., where he was born July 20, 1870. As a student of archeology had made several investigations of that vicinity and was the author of a book "The Sewickley Indian," describing an ancient tribe of Pennsylvania. He studied at the University of Pennsylvania and Cornell University, and from the latter obtained his M.E. degree in 1893. For two years he was with the Westmoreland Coal Company, following which he commenced his long service with Westinghouse.

William Isaac Donshea (A'03-M'13) retired, died December 21, 1931. Mr. Donshea was born in New York City August 2, 1858. After completing his education, Mr. Donshea's first position was with the New York Telephone Company as operator and inspector in 1879-80, which position he left to become electrician and general superintendent, installing telephone exchanges in South America for the Telephone Company of Brazil from 1880 to 1887. During the years 1882-5 he also assisted in installing an Edison exhibition "electric" plant at the National Industrial Exhibition in Rio de Janeiro; a Thomson-Houston exhibition electric plant in Rio de Janeiro, and an Edison-Swan electric light plant in a Brazilian industrial mill. Following this and up to 1929 Mr. Donshea was an operating electrician and a district operating superintendent with the New York Edison Company. In 1929 he retired from active service after 50 years in the electrical industry.

# Local Meetings

## Future Section Meetings

**Akron**

Jan. 12—X-Ray Inspection of Welds, by Ancel St. John, pres., St. John X-Ray Service Corp. Movies: "Story of Steel." Meeting to be held in the auditorium of the Ohio Edison Co.

Feb. 9—At 4:00 p.m. inspection trip through the Ohio Edison Company's East Akron substation. At 7:45 p.m. movies: "Through Oil Lands." At 8:15 p.m. James H. Foote, Allied Engineers, Inc., will speak on Load Shifting Transformers at Salt Springs. Meeting to be held in the auditorium of the Ohio Edison Co.

**Chicago**

Jan. 7—Control of Noise and Vibration in Station Design, by P. E. Stevens, Byllesby Engg. and Mgmt. Corp.

Feb. 10—Modern Underground Cable Practise, by Herman Halperin, Commonwealth Edison Co.

**Cleveland**

Jan. 21—Some Institute Problems, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co.

Feb. 18—Lightning—Recent Investigations and Findings, by K. B. McEachron, Genl. Elect. Co., Schenectady, N. Y.

**Dallas**

Jan. 18—General Developments of 1931, covered by engineering students of the Southern Methodist Univ. Student Branch.

**Detroit-Ann Arbor**

Jan. 19—Ladies' night.

Feb. 16—Fundamental Physical and Psychological Aspects of Television, by J. O. Perrine, Am. Tel. & Tel. Co. Demonstrations. Meeting to be held in the auditorium of the Michigan Bell Tel. Co.

**Lehigh Valley**

Jan. 15—Primary Network Distribution Systems, by D. K. Blake, Gen. Elec. Co. Meeting to be held at Packard Lab. Lehigh Univ., Bethlehem, Pa.

Feb. 12—Airplane and Ship-to-Shore Communication. Speaker to be announced. Meeting to be held in Scranton.

**Louisville**

Jan. 22—Practical Application of Light Sensitive Cells, by J. V. Briesky, Westinghouse Elec. & Mfg. Co.

Feb. 19—Lightning—Recent Investigations and Findings, by F. W. Peek, Jr., Genl. Elect. Co., Schenectady, N. Y.

**Lynn**

Jan. 6—Ladies' night.

Jan. 16—Inspection trip to Loose Wiles Biscuit Co.

Jan. 20—Local convention. Subject: Centrifugal Air Compression.

**Pittsburgh**

Jan. 12—Dinner meeting. Speaker: Dr. C.E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Joint meeting with student Branches.

Feb. 9—New Developments in Mercury Arc Rectifiers. Speaker from the Westinghouse Elec. & Mfg. Co.

**Pittsfield**

Jan. 19—Personal Turn of Foreign Power Systems, by Philip Sporn.

Feb. 2—Jungle Gods, by Capt. Carl Von Hoffman.

Feb. 16—Man-Made Islands to Speed Ocean Flying, by E. R. Armstrong.

**Seattle**

Jan. 19—Presentation of papers submitted for annual prize competition. Titles and speakers to be announced.

Feb. — —Communication meeting. Speaker to be provided by the Am. Tel. & Tel. Co. Joint meeting with Inst. of Radio Engrs.

**Vancouver**

Jan. 4—Subject and speaker to be announced.

Feb. 1—Metering, by F. J. Bartholomew, Elec. Pwr. Equipment Co., and L. B. Stacey, Packard Elec. Co.

## Past Section Meetings

**Akron**

Oil Purification, by R. P. Dunmire, vice-pres., The Buckeye Lab., Inc. Dinner meeting. Nov. 10. Att. 52.

**Atlanta**

Spain and America, by M. L. Brittain, pres., Georgia School of Tech. Oct. 12. Att. 80.

Technical Achievements vs. Social Responsibility, by J. E. Thomas, Commonwealth & Southern Corp. Joint meeting with A.S.M.E. Nov. 23. Att. 169.

**Baltimore**

Research, Theory, and Practise, by E. L. Manning, Genl. Elec. Co. Demonstrations. Dinner meeting. Nov. 20. Att. 57.

**Boston**

Adventures in Science, by L. A. Hawkins and E. L. Manning, Genl. Elec. Co. Demonstrations. Joint meeting with engineering societies of Boston. Nov. 12. Att. 3,600.

**Chicago**

Adventures in Science, by L. A. Hawkins, Genl. Elec. Co. Joint meeting with the Western Soc. of Engrs. Nov. 28. Att. 392.

**Cincinnati**

New Conceptions in Physics, by Dr. R. C. Gowdy, dean of the college of engineering and commerce, Univ. of Cincinnati. Illustrated. Considerable discussion. Dinner meeting. Oct. 29. Att. 65.

Power System Stability, by Robert Treat, Genl. Elec. Co. Motion pictures showed short circuit tests on the system of the New England Pwr. Co. Nov. 12. Att. 60.

**Cleveland**

Licensing of Engineers, by Dr. W. B. Kouwenhoven of The Johns Hopkins Univ., (Baltimore) vice-pres. A.I.E.E.; Engineering in Russia, by A. G. McKee, pres., Arthur G. McKee & Co. November 19. Att. 281.

**Connecticut**

Modern and Practical Uses of Illumination, by A. J. Sweet, Westinghouse Lamp Co. Dinner meeting. Nov. 19. Att. 50.

**Dallas**

International Telephone Service, by H.S. Osborne, Am. Tel. & Tel. Co., N.Y Illustrated. Nov. 23. Att. 86.

**Detroit-Ann Arbor**

Power System Stability, by Robert Treat, Genl. Elec. Co. Dinner meeting. Nov. 10. Att. 125.

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Dec. 1. Att. 175.

**Erie**

Effects of Electric Shock, by Dr. W. B. Kouwenhoven, of The Johns Hopkins Univ., (Baltimore) vice-pres. A.I.E.E.; European Travelogue, by J. J. Burgoyne, New York Central Rr. Co. Annual banquet and ladies' night at which James Burke of Burke Elec. Co., acted as toastmaster. Nov. 20. Att. 86.

**Fort Wayne**

The Hysteresis Motor, by S.L. Moore, Genl. Elec. Co.; A New Technique in Cathode Ray Oscillography, by C. M. Summers, Genl. Elec. Co. K. E. Ross, Genl. Elec. Co. demonstrated the cathode ray oscillograph. Nov. 19. Att. 80.

**Houston**

International Telephone Communication, by H. S. Osborne, Am. Tel. & Tel. Co., N. Y. Nov. 27. Att. 68.

**Iowa**

Coordination Between Electric Supply Lines and Communication Lines, by H. H. Carl, Northwestern Bell Tel. Co. Demonstrations. Oct. 29. Att. 39.

**Lehigh Valley**

Recent Developments in Surge-Proof Transformers, by H.V.Putman, Westinghouse Elec. & Mfg. Co. Illustrated. L. A. Phillips, Penn. Pr. & Lt. Co., and O. A. Griesemer, Lehigh Portland Cement Co., received prizes for obtaining the largest numbers of national and local members during the past season. Oct. 16. Att. 99.

**Los Angeles**

The Metropolitan Aqueduct, by F.E. Weymouth; Electrical Problems on the Aqueduct, by J. M. Gaylord. Both speakers are connected with the Metropolitan Water District. Dinner meeting. Nov. 10. Att. 205.

**Louisville**

The Mercury Arc Rectifier in Modern D-C. Railway Service, by E.M. Bill, Genl. Elec. Co. Also inspection trip to see the 1,000-kw. 600-volt automatic rectifier installed at the Highland substation of the Louisville Gas & Elec. Co. Nov. 20. Att. 145.

**Lynn**

The Call of the North, by A. H. Merritt. Illustrated. Nov. 4. Att. 1,200.

Inspection trips made Nov. 7 and 14 to the new building and plant of the Boston Herald-Traveler. Total att. 250.

Low Voltage A-C. Network, by O. L. Riggs, Lynn Gas & Elec. Co.; Low Voltage Metering Methods, by H. F. Crotty, Genl. Elec. Co.; Astronomical Time Switches, by F. W. Hottenroth, Genl. Elec. Co. Slides and working models used to demonstrate important features. Nov. 17. Att. 240.

**Memphis**

N.H. Brown, dean of the college of engineering, Arkansas A. & M. College, related instances from his experiences during the infancy of the electrical industry. Nov. 10. Att. 30.

Modern Methods in Aerial Photographic Mapping, by C. H. Birdseye, pres., Aerotopograph Corp. of America. Joint meeting with the Engineers' Soc. of Milwaukee. Sept. 16. Att. 200.

Some Factors Affecting Noise in the Telephone Circuits Arising in Induction Exposures, by H. R. Huntley, Am. Tel. & Tel. Co., N. Y. Illustrated by lantern slides and a complete miniature hook-up of telephone and transmission lines. Joint meeting with Engineers' Soc. of Milwaukee. Oct. 21. Att. 200.

Continuous, Quick-Freeze Process for the Manufacture of Ice, by Wm. H. Taylor, read by Harry Sloan. Motion pictures and slides. Joint meeting with Engineers' Soc. of Milwaukee. Nov. 18. Att. 175.

**Minnesota**

Modern Trends in Illumination, by O. P. Cleaver, Westinghouse Lamp Co. Dinner meeting. Nov. 19. Att. 55.

**Niagara-Frontier**

Keeping Up with Buffalo's Growth—the Changing Requirements for Telephone Service in a Growing City, by B. K. Boyce, N. Y. Tel. Co. Informal dinner at Hotel Statler preceded the meeting. Nov. 20. Att. 115.

**North Carolina**

Incandescent Lamp Efficiency Life Tests, by D. J. Thurston, student, Univ. of No. Carolina; Practical Relay Applications to Transmission Systems, by O. L. Giersch, Duke Pwr. Co.; High-Speed Protective Relays, by A. R. Van C. Warrington, Genl. Elec. Co. Dinner preceding meeting addressed by L. S. O'Roark of the Bell Tel. Lab., Inc., N. Y., on Experiments in Speech and Music. Those elected to take office Jan. 1, 1932, were announced as follows: J. E. Lear, *chairman*; R. L. Stainback, *secy.-treas.*; E. P. Coles, Raymond Hunt, J. E. S. Thorpe, and J. H. Paget, *members exec. committee*. Nov. 10. Att. 115.

**Oklahoma City**

The Arthur S. Huey Memorial Station, by Otis Howard, Oklahoma Gas & Elec. Co. Inspection trip through the station followed. Oct. 30. Att. 60.

International Telephone Service, by H. S. Osborne, Am. Tel. & Tel. Co., N. Y. Dinner meeting. Nov. 20. Att. 85.

**Philadelphia**

Air Conditioning, by J. F. Gaskill, Phila. Elec. Co. Nov. 9. Att. 185.

**Pittsburgh**

Lightning Protection of Overhead Transmission Systems, by W. W. Lewis, Genl. Elec. Co. Joint meeting with the Engineers' Soc. of Western Pa. Nov. 10. Att. 171.

**Pittsfield**

Electrical Research, by E. L. Manning, Genl. Elec. Co. Demonstrations. Dinner meeting. Nov. 3. Att. 950.

Fused Quartz, by P. K. Devers, Genl. Elec. Co. Illustrated. Dinner meeting. Nov. 17. Att. 250.

**St. Louis**

International Telephone Service, by H. S. Osborne, Am. Tel. & Tel. Co., N. Y. Nov. 18. Att. 78.

**San Antonio**

International Telephone Service, by H. S. Osborne, Am. Tel. & Tel. Co., N. Y. Illustrated. Nov. 24. Att. 68.

**Schenectady**

Annual meeting. Oct. 8. Att. 90.

Construction of the George Washington Bridge, by E. W. Stearns, Port of New York Authority. Illustrated. Joint meeting with A.S.M.E. Oct. 29. Att. 250.

Human Engineering, by Col. C. R. Gow, Warren Brothers Co., and prof. of humanics at M.I.T. Joint meeting with the A.S.M.E. Nov. 19. Att. 260.

The Autogiro, by A. E. Larsen, Autogiro Co. of America. Moving pictures. Joint meeting with the A.S.M.E. Dec. 10. Att. 320.

**Seattle**

The Skagit River Power Development, by J. D. Ross, supt. of lighting, City of Seattle. Illustrated. Dinner meeting. Nov. 17. Att. 85.

**Spokane**

Advantages of the New Cascade Tunnel and Main Line Electrification of the Great Northern Railway, by Glen Walker, Great Northern Co. Film—"Electrified Operation of Trains." Nov. 27. Att. 52.

**Syracuse**

Trends in Improvement of Electric Service, by F. A. Hamilton, Jr., Genl. Elec. Co. Slides and moving pictures. Oct. 26. Att. 163.

**Toledo**

Electrons at Work and at Play, by Phillips Thomas, Westinghouse Elec. & Mfg. Co. Demonstrations. Joint meeting with the Affiliated Tech. Societies of Toledo. Nov. 12. Att. 1,200.

System Operation, by F. H. Dubs, Toledo Edison Co.; Power Transformer Design and Tap Changing Under Load, by L. H. Hill, Allis-Chalmers Co. Considerable discussion. Nov. 20. Att. 80.

**Toronto**

Recent Developments in Oil Circuit Breakers, by G. R. Langley, Canadian Genl. Elec. Co. Moving pictures and slides. Nov. 13. Att. 124.

Circuit Breakers for Branch Circuits, by O. S. Jennings, Westinghouse Elec. & Mfg. Co. Demonstrations. Nov. 27. Att. 100.

**Urbana**

Contribution of the Physical Sciences to Human Welfare, by Prof. C. T. Knipp, Univ. Illinois. Demonstrations. Nov. 17. Att. 58.

**Washington**

Registration of Engineers, by Dr. W. B. Kouwenhoven of the Johns Hopkins Univ. (Baltimore) vice-pres. A.I.E.E. Dinner meeting. Nov. 10. Att. 65.

**Worcester**

Uses of the Thyratron Tube, by R. H. Rogers, Genl. Elec. Co. Nov. 12. Att. 60.

## Past Branch Meetings

**University of Alabama**

Joint meeting A.S.C.E. chapter—motion pictures and talks by students. Nov. 16. Att. 40.

**University of Arizona**

Electronic Music, by T. S. Henderson, student. Oct. 16. Att. 5.

Carrier Waves, by C. A. Ferguson, Am. Tel. & Tel. Co. Dinner meeting. Oct. 23. Att. 14.

Thomas Alva Edison, by H. P. McGovern, student. Illustrated. Oct. 30. Att. 7.

The Electron Tube Voltmeter and Ammeter, and the Phase Shifting Bridge, by P. F. Hawley, student. Nov. 6. Att. 7. Film—"The Single Ridge." Nov. 13. Att. 6.

**University of Arkansas**

Lead Acid Batteries, by H. H. Lewis, student; Storage Battery Application, by Erle Cato, student; Review of the Electrical World, by Luther Hildebrand, student; Resistance, by Eugene Ray, student; The Life and Works of Edison, by L. Wasson, student. Nov. 11. Att. 38.

Magnetism, by E. E. Boreland, student; Illumination of Athletic Fields, by F. L. McDonald, student; Research Work, by J. H. Nelson, student. Dec. 2. Att. 42.

**Armour Institute of Technology**

Transmission of Pictures by Wire, by S. R. Sjoderberg, Am. Tel. & Tel. Co., assisted by E. E. Albin. Illustrated. Nov. 7. Att. 65.

Two-Speed Continuous Automatic System, by E. G. Stecher, Chicago and Northwestern RR. Co. Illustrated. Nov. 21. Att. 35.

Film—"The Electric Ship." Dec. 4. Att. 65.

**University of British Columbia**

The Thury System of D-C. Distribution, by G. G. Henderson, student; The Control of High Frequency Oscillators by Means of Quartz Crystals, by A. C. Tregidga, student. Nov. 16. Att. 9.

**Brooklyn Polytechnic Institute**

The Problems Confronted in the Design of a Commercial Short-Wave Receiver for Operation from A. C. Mains, by L. A. DeRosa, student; The Theory of the Induction Voltage Regulator, by Frank Anderson, student. Dec. 2. Att. 19.

**Bucknell University**

Prof. G. A. Irland, counselor, discussed the aims and activities of the A.I.E.E. and stressed the importance of student enrolment. J. A. Everitt elected secy.-treas. Nov. 4. Att. 14.

**California Institute of Technology**

J. R. Howell, Sterling Motor Co., described the characteristics and construction of sterling motors. Nov. 18. Att. 36.

**University of California**

Construction Features of the Hoover Dam, by W. C. Johnson, Westinghouse Elec. & Mfg. Co. Three students presented papers on the life of Michael Faraday. Nov. 10. Att. 31.

Short Cuts in Complex Numbers, by W. J. McLeod, student. Films—"Big Deeds" and "Power Transformers." Nov. 24. Att. 42.

Election of officers: J. J. Cassidy, *chairman*; H. C. Kruger, *vice-chairman*; S. L. Bettis, *secy.*; C. P. Van Camp, *treas.* Dec. 2. Att. 9.

**Carnegie Institute of Technology**

Switchboards and the Work of the Switchboard Engineer, by A. J. Peterson, Westinghouse Elec. & Mfg. Co. Nov. 13. Att. 36.

**Case School of Applied Science**

Resuscitation from Electric Shock, by G. E. Smith, Ohio Bell Tel. Co. Dinner meeting. Dec. 3. Att. 29.

**Catholic University of America**

H. G. Dorsey, U.S. Coast & Geodetic Survey, showed slides illustrating wiring diagrams of the "fathom meter," used to find the depth of water at desired points. Nov. 12. Att. 39.

**University of Cincinnati**

The Application of Fuses to Electrical Distribution Systems, by Frank Sanford, Union Gas & Elec. Co. Nov. 11. Att. 65.

**Clemson Agricultural College**

Practises that Improve the Operation of Electrical Equipment, by C. P. Walker, student. Illustrated lecture on the Genl. Elec. Co. by V. L. Bethea, student. Nov. 5. Att. 40.

Prof. C. M. Asbill gave a talk on radio. Current events presented by J. L. O. Foster, student Nov. 19. Att. 35.

**Colorado State Agricultural College**

Post Graduate Work and Advanced Degrees, by Prof. H. G. Jordan. Dale Pinkerton elected secy. Nov. 9. Att. 24.

**University of Colorado**

Film—"The Story of Nitrocellulose." Nov. 18. Att. 61.

**Cornell University**

The aims and activities of the A.I.E.E. were outlined by Prof. P. M. Lincoln and Prof. R. F. Chamberlain. Nov. 6. Att. 33.

**University of Denver**

Inspection trip to the Valmont plant of the Pub. Serv. Co. of Colo. Nov. 7. Att. 13.

The Effect of Physical Stresses on Magnetic Materials, by Martin Eisendorfer. Dec. 1. Att. 14.

**University of Detroit**

Set Checkers and Radio Maintenance, by J. C. Hoover, Hoover Lab., Inc. Film—"Wizardy of Wireless." Nov. 12. Att. 60.

**Drexel Institute**

Problems of Modern Physics, by Dr. T. H. Johnson, asst. director, Bartol Research Lab. of Swarthmore College. Nov. 19. Att. 36.

**Duke University**

Debate, in which four students participated: Resolved: That Hydro Power is More Economical for the Generation of Electric Power than Steam Power. Nov. 19. Att. 20.

**University of Florida**

Power Distribution for Rapid Transit Lines and Dynamic Braking, by F. B. Gaines, student. Film—"Making of Mazda Lamps." Nov. 18. Att. 45.

Development of the College of Engineering at the University of Florida, by Howard Rybolt, student. Dec. 3. Att. 100.

**Georgia School of Technology**

Three films: "Thomas A. Edison," "Liquid Air," and "How the General Electric Icing Unit Works." Nov. 10. Att. 55.

**Harvard University**

Some Rocks Ahead, by Prof. Philip Cabot. Nov. 19. Att. 77.

**University of Illinois**

Film—"Dynamic America." Nov. 11. Att. 40.

**University of Iowa**

Multi-Mu and Pentode Tubes, by Wendell Seward, student; Induction Furnace, by Jack Sayer, student; Life and Works of Thomas Edison, by Leonard Sahs, student. Oct. 28. Att. 41.

Some Acoustical Problems of Electrical Engineering, by Harold Petersen, student; Modern Street Lighting Practise, by R. K. Meyer, student. Nov. 4. Att. 39.

Film—"The Single Ridge." Nov. 18. Att. 42.

**Kansas State College**

Talk by Arthur Groesbeck of the United Pwr. & Lt. Corp. Moving pictures. Nov. 5. Att. 54. Afternoon meeting. Program repeated same evening. Att. 33.

The Engineer's Work in a Power Company, by Ivan Buys, United Pwr. & Lt. Corp. Dec. 3. Att. 54. Afternoon meeting. Program repeated same evening. Att. 36.

**University of Kansas**

Several 1-min. talks by students and faculty members. Nov. 19. Att. 20.

**University of Kentucky**

Southern California Power Development, by Prof. E. A. Bureau. Nov. 18. Att. 41.

**Lafayette College**

The Bulls Bridge Hydroelectric Power Development, by Richard Brunn, student. Illustrated. November 20. Att. 14.

**Lehigh University**

Thomas Alva Edison, by Sidney Land, student. Illustrated; Four Months in Europe, by Dean Joseph W. Barker, Columbia Univ. Nov. 19. Att. 85.

**Lewis Institute**

The Routine of a Telephone Call, by L. P. Evans, student; The Handling of a Telegram, by M. H. Dressler, student. Nov. 16. Att. 50.

**University of Louisville**

Sound Equipment, by C. C. Baines, Samson Elec. Co. Demonstrations of sound apparatus. Nov. 13. Att. 26.

**University of Maine**

R. E. Young, chairman, outlined the activities at the district meeting held in Rochester in April, 1931. Prof. W. E. Barrows outlined his experiences at the silver jubilee of the Illuminating Engg. Soc. held at Pittsburgh. Oct. 22. Att. 24.

Thomas Edison's Life and Work, by Raymond Hunter, student; Faraday's Life and Work, by Henry Howes, student. Nov. 12. Att. 16.

**Massachusetts Institute of Technology**

Inspection trip through the plant and laboratories of the Simplex Wire & Cable Co. Nov. 4. Att. 30.

The Generation and Distribution of Electric Power, by E. S. Mansfield, Edison Elec. Illum. Co. of Boston. Film—"More Power to You." Nov. 19. Att. 225.

Inspection trip to the Edgar station of the Edison Elec. Illum. Co. of Boston at South Weymouth. Nov. 23. Att. 25.

**Michigan College of Mining and Technology**

W. D. Stewart, student, gave an illustrated lecture on turbo-generators, Equipment and Operation of Radio Station WHDF at Calumet, Mich., by K. M. Smith, student. Nov. 19. Att. 31.

**Michigan State College**

Experiences in Russia, by Mr. McElroy. Joint meeting with A.S.C.E. and A.S.M.E. Branches. Nov. 12. Att. 23.

A Day in the Weather Bureau, by Prof. Seelye, U.S. Weather Bur. at East Lansing. Dec. 8. Att. 24.

**University of Michigan**

The Placement, Training, and Eventual Work of the Engineering Graduate, by W. A. Furst, Westinghouse Elec. & Mfg. Co. Nov. 24. Att. 102.

**Missouri School of Mines and Metallurgy**

L. K. Johnson, student, outlined his experiences while employed by the Genl. Elec. Co. Nov. 4. Att. 16.

Demonstrations. Nov. 18. Att. 15.

**Montana State College**

General Electric Training, by George Lamb; Radio Transmitter Filter Circuits, by H. L. Casey; Nature's Freak—Ball Lightning, by P. B. McAdam, student; The Way to Prosperity and Progress, by C. E. Grunsky, taken from the Oct. 1931 issue of Electrical Engineering, presented by Wm. H. Scheele, student. Nov. 5. Att. 103.

Montana Section as guests of the Branch witnessed displays and demonstrations presented by students. Refreshments. Nov. 19. Att. 462.

**University of Nebraska**

Inspection trip through the offices of Dr. R. L. Smith; X-ray equipment displayed and uses demonstrated. Nov. 4. Att. 50.

**Newark College of Engineering**

Development of Television, by G. R. Ottinger, N. J. Bell Tel. Co. Illustrated. Nov. 23. Att. 46.

**University of New Hampshire**

Michael Faraday's Rise to Fame, by H. L. Wood, student; Combating Magnetism in Watches, by B. Booth, student; The Physical Analysis of Water Coming from a Paper Mill, by L. A. Barker, student; The Advancement of the Turbo-Generator, by J. L. Currier, student. Oct. 3. Att. 32.

The Development of the Microphone, by O. F. Cushman, student; Electricity in Agriculture in Sweden, by H. T. Dickson, student; Another Cure for the Business Depression, by A. E. Dogan, student. Oct. 17. Att. 25.

G. L. Freese, student, described the new bridge to be constructed between Newington and Durham; Functions and Benefits of the A.I.E.E., by P. A. Rolfe, student. Oct. 24. Att. 29.

Illumination of the Home, by C. M. Glidden, New Hampshire Gas & Elec. Co. Illustrated. Nov. 7. Att. 33.

Some of the Problems in the Distribution Department at Cambridge, Mass., by James Allen, New England Gas & Elec. Co. Nov. 18. Att. 45.

### University of New Mexico

M. A. True, chairman, outlined the aims and activities of the A.I.E.E. Nov. 6. Att. 33.

History and Theory of Electrical Precipitation of Solids from Gases, by S. O. Fish, student. Nov. 17. Att. 18.

### New York University

Relays, by G. M. Heckel, student; Arc Welding, by L. Lindorf, student. Oct. 27. Att. 14.

### University of North Carolina

Calculation of Three-Phase Short-Circuit Currents, by O. L. Giersch, Duke Pwr. Co. Nov. 12. Att. 35.

### University of North Dakota

Michael Faraday, by E. Besken, student; Joseph Henry, by Geo. Anderson, student. Nov. 11. Att. 10.

### University of Notre Dame

The Use of Transformers in Telephony, by Henry Cluver, student; The Manufacture of Sound Equipment, by H. H. Shotwell, Operadio Mfg. Co. John Scanlon, student, presented the bi-monthly engg. digest. Nov. 16. Att. 75.

Neon Signs as Used in Advertising, by E. W. Kenefake, student; Commercial Illumination, by O. P. Cleaver, Westinghouse Elec. & Mfg. Co. John Scanlon, student, presented the engg. digest. Nov. 30. Att. 65.

### Ohio State University

Several students gave talks in commemoration of Michael Faraday. Dinner meeting. Nov. 5. Att. 18.

Some Institute Problems and the Electrical Industry, by Dr. C. E. Skinner, pres. A.I.E.E., and asst. director of engg., Westinghouse Elec. & Mfg. Co. Dinner meeting. Nov. 20. Att. 50.

### Ohio University

Making Electrical Transcriptions, by Prof. D. B. Green. Nov. 11. Att. 44.

Prof. W. H. Cooper gave a talk in which he compared the engg. students with students of other professions. Dinner meeting. Dec. 9. Att. 46.

### Oklahoma A. & M. College

Thomas A. Edison, by E. E. Moore, student. Nov. 9. Att. 24.

### Pennsylvania State College

Four students outlined their experiences during summer employment. Oct. 28. Att. 23.

Why Auto Axles Break, by Dr. E. C. Woodruff. Nov. 18. Att. 90.

### University of Pittsburgh

R. E. Bishop, student, outlined his experiences while doing cooperative work with the Ohio Pwr. Co. Oct. 29. Att. 121.

Life and Work of Thomas Edison, by T. Namlick, student; Report on Academy of Arts and Sciences, by J. V. Heisch, student. Nov. 5. Att. 121.

Copper Oxide Rectifiers, by H. L. Lammy, student. Nov. 12. Att. 122.

Secret Service System, by G. S. Onori, student. Nov. 19. Att. 120.

### Pratt Institute

Historical Development of Modern Physical Theories, by J. E. Thompson. Nov. 5. Att. 74.

Manufacture and Testing of Ward-Leonard Vitrohm Resistors, by H.F.McCord, student. Nov. 19. Att. 31.

Sound Reproduction in Talking Pictures, by O. W. Hancock, student. Dec. 3. Att. 20.

### Princeton University

Thyratron Commutator Motor, by Prof. C. H. Willis. Nov. 23. Att. 12.

Communication Problems of Power Utilities, by L. K. Wyatt, student; Pennsylvania Electrification, by L. Thomas, student; Lightning Arresters, by M. Kine, student. Dec. 9. Att. 6.

### Rensselaer Polytechnic Institute

Some Picturesque Spots in the Development of the Incandescent Lamp, by Samuel Ferguson, Hartford Elect. Lt. Co. Nov. 17. Att. 120.

### Rhode Island State College

Electric Welding, by L. C. Breault and B. Porter, students. Oct. 15. Att. 21.

Lagging of Watthour Meters, by Mr. Mobrey. Nov. 5. Att. 34.

Life of Thomas A. Edison, by L. M. Lang, student. Illustrated. Nov. 12. Att. 17.

Airport Lighting, by Geo. Freeman, student; Radio Communication on Trains, by Edward Long, student. Nov. 19. Att. 15.

### The Rice Institute

Film—"Power." Nov. 18. Att. 21.

General discussion. Dec. 3. Att. 13.

### Rose Polytechnic Institute

Life of Faraday, by Wm. Hineline, student. Nov. 25. Att. 36.

Film—"The Magic Circle." Dec. 7. Att. 101.

### University of Santa Clara

Film—"Modern Methods of Riveting." Joint meeting with A.S.M.E. Branch. Nov. 12. Att. 104.

Report of San Francisco A.S.M.E. and A.S.C.E. Section meetings given respectively by Gale Sullivan and A. Porter, students. Joint meeting with A.S.M.E. and A.S.C.E. Branches. Nov. 19. Att. 95.

### University of South Carolina

Film—"Thomas A. Edison," Nov. 5. Att. 42.

Business meeting. Nov. 12. Att. 11.

Santee River Hydroelectric Project, by L. E. Rankin, student; Application of Fourier's Series to Distorted Current Waves, by W. S. Smith, student; Hydroelectric Project on Broad River, by A. B. Urquhart, student. Nov. 19. Att. 43.

### South Dakota State School of Mines

Industrial Control, by F. H. Doremus, Genl. Elec. Co.; The Modern Trend in Steam Turbine Design, by R. A. Halse, Genl. Elec. Co. Nov. 4. Att. 37.

### University of Southern California

E. R. Stauffacher, So. California Edison Co., Ltd., described relay applications on the Edison system. Oct. 27. Att. 31.

M. W. Edwards, Municipal Lt. and Pwr. Dept., City of Pasadena, spoke on the development and expansion of their power plant and interconnecting systems. Nov. 4. Att. 25.

### Stevens Institute of Technology

Motorless Aviation, by H. W. Braendel, student. Nov. 13. Att. 40.

### University of Utah

Inventions of Thomas A. Edison, by S. Ramo, student; Development of the Incandescent Lamp, by F. C. Derrick, student. Nov. 5. Att. 30.

Salesmanship as Related to Engineering, by Mr. Ferguson, Utah Pwr. & Lt. Co. Nov. 19. Att. 35.

### University of Vermont

Prof. L. P. Dickinson, counselor, gave an illustrated lecture on the life and work of Thomas A. Edison. Oct. 26. Att. 20.

Various Types of A-C. Rectifiers, by Prof. L. P. Dickinson, counselor. Nov. 9. Att. 18.

### Virginia Military Institute

Life of Edison, by W. S. Hayman, student; Modern Electricity, by W. L. Calhoun, student; Life of Steinmetz, by F. B. Epps, student; Lightning Electricity, by N. W.Lingman, student. Nov. 14. Att. 57.

### Virginia Polytechnic Institute

Hardening Metals by Magnetism, by A. de Villesante, student; Power Plant of the Akron, by R. C. Beverly, student; Boulder Dam, by C. Gratz, student. Nov. 11. Att. 50.

Rectification of Alternating Current, by D. E. Williams, student; Virginian Railway Power Plant at Narrows, Va., by C. R. Settle, student. Nov. 19. Att. 47.

### State College of Washington

Dean H. V. Carpenter, vice-pres. A.I.E.E., reviewed activities at the 1931 Pacific Coast convention. Oct. 27. Att. 22.

Life and Works of Thomas A. Edison, by D. H. Olney, student. Nov. 17. Att. 34.

### University of Washington

Captain Crim, U.S. Army Ordnance, described methods of electrical firing control. Illustrated. Nov. 12. Att. 27.

Photoelectric Cells and Their Application to Sound Reproduction, by Floyd Norris, student. Nov. 19. Att. 13.

Rock Island Project on the Columbia River, by L. R. Coffin, Puget Sound Pr. & Lt. Co. Dec. 3. Att. 19.

### West Virginia University

Rural Power Transmission, by L. E. Palmer; Arc Welding, by Wm. P. McCue; Ways of Proving Good Welds, by R. W. Blair; D-C. Controlled Relays, by A. W. Friend; Circuit Breakers in the Home, by J. L. Simpson; Transmission and Distribution of Electric Energy, by J. E.Wallace, all students. Nov. 9. Att. 30.

Modern Practises in the Use of Electric Power, by M. Stewart; The Earth's Electric Charge, by F. D. Brown; Night Photography, by E. P. McCue; Electrical Appliances at the Nemacolin Mine, by V. Montieth; Welded Building Construction, by A. Higgins; all students. Nov. 2. Att. 30.

Thomas A. Edison, by Philip Skaff, student. Illustrated. Film—"The Single Ridge," Nov. 9. Att. 30.

### University of Wisconsin

Thyratron Tubes, by C. V. Bullen, student; Calculation of Magnetic Flux Density, by K. J. Rhodes, student. Nov. 9. Att. 67.

### University of Wyoming

Theoretical Functioning of Gaseous Tubes Used for Illumination, by Albert Buchholz and LeRoy Border, students; Practical Application of Gaseous Tubes Used for Illumination, by H. Soule, Western Pub. Ser. Co. Nov. 17. Att. 25.

## Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Balaguer, Manuel M.,c/o International Tel. & Tel. Co.,67 Broad St.,New York, N. Y.
Cater, C.,Sandal, Church Road, Pinner, Eng.
Chilofsky, Joseph, 958 N. 7th St.,Phila. Pa.
Cordier, N.A., 126 Chatterton Pkwy., White Plains, N. Y.
Farnlof, Charles G.T.,1318 Laketon Rd.,Wilkinsburg, Pa.
Gaylord, R.H.,1814 Virginia Rd.,Los Angeles, Calif.
Goldsman, Jacob L.,64 Priory Rd.,Hampstead, London, Eng.
Kamm, J. Lloyd, 1801 N. Lamar St.,Dallas, Texas.
McCulloch, G.B.,McVie Caterers, Ltd.,Sydney, N.S.W.,Australia.
Melson, Sydney W.,Yeatton Woolrich Rd., Abbey Wood, London, S.E.2, England.
Mountain, C.E.,Burma Elec. Supply Co.,Mandalay, Burma, India.

Parr, J.C., 245-71st St., Bklyn., N.Y.
Pierson, Walter D., 4710 Locust St., Phila, Pa.
Pistorius, L.H., 193 Jeppe St., Johannesburg, South Africa.
Schrock, John E., 3720 Main St., Lawrence Park, Erie, Pa.
Stempfle, Frederich, 8126 E. Vernor Highway, Detroit, Mich.
Tate, William, Apartado No. 41, Pula, Mexico.
Thakkur, K.B., Box 654, Whiting, Ind.
Voronovsky, T.G., 1162 Waverly Place, Schenectady, N.Y.

# Employment Notes

## Of the Engineering Societies Employment Service

### Men Available

GRAD. E. E., 24, single, B.S. in E. E., W.P.I. 1931; 4 yr. experience in construction; one in transmission work. Desires work in any E.E. field. Available at once. Location optional. D-45.

1931 GRAD. E.E. of 5-yr. cooperative school, 23, single. Experience includes machine shop practise, telephone central office trouble shooting, and service with large municipal fire alarm system. Desires position with mfg. concern or pub. utility. Will start at bottom. Middle West preferred, elsewhere satisfactory. C-9825.

DESIGN ENGR., col. grad., 38, married; 9 yr. elec. substation and powerhouse design, with switchboards, wiring diagrams, and all other important items; 5 yr. test engr. pwr. station and research labs. Fluently speaks Spanish, German, and Hungarian. Available immediately. U.S.A. or foreign. C-9128.

FINANCIAL ENGR., Cornell (ME-EE); 12 yr. regulatory commission; 4 with utility holding mgnt. corp., 8 months intensive course bond buying dept. leading insurance company; employed almost 4 yr. thereafter on financial and fact-finding investigations by outstanding cons. engg. organization. Desires opportunity New York City. Salary open. C-2953.

M.I.T. GRAD. E.E., 35, married. 6 yr. industrial and teaching experience in E.E. Several years private research and dev. work on own initiative. Good ability, integrity, and personality. Desires univ. teaching for life work. Mid West or South preferred. C-2826.

E.E., grad. southern univ., married, 34, G.E. Test; 10 yr. in utility engg. and maintenance work, (8 on underground distr. system incl. a-c. low voltage networks); desires position with utility in design or maintenance of distr. system. Location immaterial. C-1191.

GRAD. E.E., 26; 9 yr. consisting of power plant and substation constr. and maintenance as draftsman and engg. asst.; street ry. electrolysis surveys; automatic substation design and supervision of construction and maintenance; industrial elect. work as draftsman and engg. asst. Location immaterial. Available at once. C-5151.

ELECT-MECH. ENGR., 28, married, M.E. deg., thoroughly competent mech. and elect. design and dev. of rotating apparatus. First-class references and record of accomplishments. Available on notice. Location immaterial. D-109.

ELECT. ENGR. B.S. from M.I.T. in 1931. American, 25, single. Desires position with mfg. or pub. utility company. Upbringing in business environments qualifies him for sales work also. Eastern states preferred, any other location considered. Available now. D-110.

GRAD. E.E., 21, single, B.S. in E.E. 1931 high scholastic record. Summer experience pub. utility. Interested in position with industrial concern or pub. utility. Available now. New York preferred but not essential. C-9467.

TECH. GRAD. eastern college, B.S. in E.E., 1927. Good tech. background. Knowledge of vacuum tubes, audio amplifiers, and sound reproducing systems. Elect. pwr. distr. and refrig. Traveled extensively as company engr. and representative. Experienced in managerial, executive, sales capacities. Desires position requiring tech. ability and sales personality. C-8231.

MOTOR CONTROL EQUIPMENT ENGR. 25 yr. experience in motor control design, particularly elect. elevator and misc. control problems and layouts. B.S. in E.E. D-120.

RESEARCH ENGR. member A.I.E.E., A.S.M.E., Am. Statistical Soc.; lately with large utility company; change due to organization curtailment. D-112.

SUPERINTENDENT. 20 yr. in the States in constr. and operation of ry., lt. and pwr. properties; 8 yr. similar work in Latin America. Working knowledge of French, Spanish, Portugese. Successful mgt. sales eastern Cuba for large importers. Prefers Latin countries. B-5729.

GRAD. E.E., 1925; 27, single; 1 yr. G.E. Test. 5 yr. engg. dept. of large lt. and pwr. utility. Constr., inspection, investigations, and tests. Desires constr. or sales engg. work, but would consider anything. Location East. Available at once. D-107.

ELECT., DESIGNING DRAFTSMAN, 37, married. 3 yr. Armour Inst., night school, E.E. 9 yr. design of stm. and hydroelect. sta. High and low voltage, substations and steel tower trans. lines, 1 yr. field engr. on trans. lines, 4 yr. constr. workman, 2 yr. operating and load dispatcher. Available now. Anywhere. C-9986-3660-Chicago.

MECH. AND ELECT. ENGR., 32, single, M.E. and E.E. 4 yr. instructor in machine design at Cornell University. 5 yr. Allis Chalmers stm. turb. design and checking, liberal shop experience. Desires at once responsible work offering future opportunities. Middle West preferred. D-122-3680-Chicago.

GRAD. E.E., 31, single, 8 yr. experience, design, and constr. of trans. lines, voltages up to, and incl. 220-kv., outdoor and indoor high voltage substation and distr. networks. Desires position in engg. or constr. dept. of large utility or holding company. Location immaterial. C-3564.

DESIGN ENGR., Westinghouse Engg. and Design School grad. Pwr. and instr. trans. design experience. Now employed. D-131.

SALESMAN, contact representative or mfr. agent; 37, experienced E.E. representative desires position with high grade company mfg. line of high or low voltage equip. for industrial plants or utilities. B-4067.

1931 E.E. Grad., Georgia Tech., cooperative plan. Single, 24, no obligations; 2½ yr. experience battery work; small turbo-generators; installation of pwr. and control equip. machine shops and oil pumping stations, and winding of fractional hp. motors. 4-yr. course Spanish. Available immediately, anywhere. D-127-3694-Chicago.

ELECT. ENGR. 32, single, B.S. E.E., additional work M.E., Phi Kappa Phi. 8 yr. board experience, powerhouse, substation, trans. line, duct system design; estimates, standards, equip. specifications, operation. Responsible, capable engineer asst. Desires position with mfr. or in plant mgnt. for utilities. Salary secondary to opportunity. D-124.

GRAD. ENGR., 41, with mech., structural and elect. experience. 10 yr. with engg. firms handling design and constr. of power and industrial plants. 2 yr. as plant engr. in large factory. Last 5 yr. with pub. utility on indoor and outdoor substations. Unemployed. A-3027.

ELECT. ENGR. 1924 grad., B.S. E.E., 29, married, 7 yr. experience testing, inspecting, installing various elect. equip. Writing reports. Asst. to mgr. pwr. and lt. utility. Purchasing elect. supplies. Available at once. Detailed information gladly given. Welcomes opportunity in operating-maintenance dept., pub. utility or mfg. concern. C-4981.

1931 E.E. GRAD. 6 yr. experience as an amateur radio operator. Experienced in radio receiving and transmitting apparatus. Desires position with radio or telephone concern. Available at once. D-76.

ELECT. ENGR. 30, married, B.S. E.E. 1924. 7 yr. experience design of synchronous motors, generators, condensers, frequency-changers of all speeds, ratings. Familiar with mech. design of synchronous machines and system stability studies. Desires employment with utility company or cons. engg. firm. Location immaterial. One month's notice. D-147.

ELECT. AND ILLUM. ENGR. member A.I.E.E., I.E.S., 16 yr. practical experience, electrician and mechanic, foreman, supt., etc. 10 yr. est. engg. for architects, etc. Some htg. and vent. experience. All around mechanic and electrician, draftsman. Wants work of some kind anywhere; eastern states preferred. C-8460.

GRAD. E.E., 22, single, B.S. E.E. 1931; two yr. experience in mfr. elect. motors and generators, constr., test, and experimental laboratory. Desires connection for design and constr. of generating plants. Prefers New Jersey, but not essential. D-159.

ELECT. ENGR. single, 26, E.E. '30. 15 months G.E. Test. 5 months experience in G.E. Research Laboratory. Desires position in engg. or test dept. of utility or mfg. company. Available at once. Location New York. D-136.

1931 GRAD. E.E. from leading college in N.Y. State desires position in the elec. industry. Experience main motive, age 25. Several languages. Location U.S.A. or any foreign country. Available immediately. D-164.

SALES ENGR., grad. M.I.T. 1925 B.S. E.E. Design experience Penna. R.R. Co., Westinghouse Test, sales course. Sales experience,

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco
N. D. Cook, Manager

205 West Wacker Drive
Chicago
L. E. Griffith, Manager

31 West 39th St.
New York
W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

domestic and export elect. equip.; financial training. Desires sales position or one where combined tech. and commercial knowledge is advantageous. At present in New York City. C-1415.

ELECT. ENGR. 28, with mech. and lab. experience. Wishes work especially in connection with elec. rys. Salary not important if work is within New York area. C-8424.

ELECT. ENGR. 24, graduate Calif. Inst. of Tech. 1931. Special training vacuum tubes and communications, also radio experience. Desires position in communications or allied fields. Will start at bottom. Location immaterial; available at once. D-171.

GENERAL ENGR. Univ. education. Westinghouse apprentice. Wide experience. 4 yr. responsible charge of pwr. and wtr. supply for large industrial corp., operating chain of plants. 7 yr. large engg. and constr. corp. Experienced in mech. design, test and operation of pwr. stations. D-172.

ELECT. ENGR., 28, single. Grad. Georgia Tech. '29, B.S. in E.E. and C.E. Westinghouse test floor, engg. school and design school. 1 yr. experience in turbine generator design, incl. dev. work. Desires position with future. Location immaterial. Available at once. C-9923.

ELECT. ENGR. univ. grad., 36, married. Background of 8 yr. experience elect. test, in field and lab. also in erecting equip. Additional 3½ yr. experience in test and manufacture of radio tubes. Desires position with mfr. or lab. Metropolitan New York preferred. Available now. B-8817.

GRAD. E.E. 25, single. B.S.'29 and M.S.'31 from M.I.T. 1 yr. G.E. Test; 4 summers gen'l maintenance work with telephone company. Available at once. Will go anywhere, to any position for which qualified. Salary secondary. D-175.

1931 GRAD. ENGR., with B.E., single, 23, American, desires position in the elect. industry with opportunity for advancement. Location immaterial. D-174.

1931 E.E. GRAD., 23, single, B.S. in E.E. at M.I.T. Summer experience in electric station of pub. utility company. Desires position with pub. utility, elect. or radio mfg. company, salary secondary. Available at once. D-180.

ELECT. ENGR., Cornell. G.E. shops. 5 yr. each: ry. elect. hydroelect. projects; heavy automotive and tractor design and operation; engg. investigations, reports South America, Orient; quantity production high voltage vacuum devices, photoelectric and neon tubes, plant equipment; director electrophysical lab. Geoelectrical surveys for water, ore; own complete equipment. C-7026.

EXECUTIVE, industrial physicist tech. grad. with diversified research experience and excellent engg. training. Desires position with American organization. Will consider opening as asst. to able engr. or business executive. B-8987.

ENGR. INSPECTOR, tech. grad., 19 yr. experience incl. test. and lab. work, valuation, mfg. prod., inspection and expediting production of elect. and mech. pwr. equip. Familiar with latest dev. in elect. pwr. equip. and transmission material. Past 9 yr. represented pub. utility company inspecting and expediting. Position desired. D-179.

GRAD. E. E., 1929, single, 23. 15 mo. as student engineer on G.E. test. Some test, drafting, and switchboard construction experience before graduation. Interested in position with firm doing cons. or constr. work or with utility or manufacturer. Available at once. Location anywhere in U.S. C-8028.

POWER PLANT MGR., SUPT., desires to make change. Married, 33. 3 yr. E.E. course, broad experience, 2 yr. U.S. Navy, 2 yr. large elect. mfg. company, 5 yr. elect. engr. ins. company. 4 yr. power-plant constr., mgt. Middle West preferred; will consider other. Short notice desired. D-187.

ELECT. ENGR., 24, single, Iowa State College, 1931. Experience limited. Desires work with pub. utility or mfg. concern. Salary second to opportunity. Available now. Anywhere in U.S. C-9827.

GRAD. OF NORTH CAROLINA STATE COLLEGE, class '31, B.S. in E.E., desires connection with illuminating concern or work with photoelectric cells. Salary no consideration. Wishes to learn business from bottom up; staying with it. D-144.

GRAD. E.E., 32, single. 3 yr. Westinghouse Test. 7 yr. supervising power plants, substation, transmission line construction. 8 yr. engg. insp., purchasing, expediting, tracer, res. engr. and writing specifications. Excellent reference. Can handle responsibility. Wants connection with pub. utility, holding company, contractor or mfr. Available immediately. Location immaterial. B-9661.

GRAD. E.E., 22, single, B.S. in E.E., 1931, desires work where 5 yr. practical experience as electrician and radiotrician will be of value. C-9896.

ELECT. ENGR., 23, single, 1931 grad., E.E. from Bklyn. Polytechnic Inst. Desires position with electrical industry with an opportunity for advancement. Salary secondary. New York preferred; not essential. D-188.

ELECT. ENGR. 45, univ. grad., experienced in the various branches of elect. engg. work of pwr. companies incl. work for industrial customers, desires position with pwr. company or mfr. Permanent position desired, but will consider temporary work. B-1923.

GRAD. E.E., 24, cooperative college. Experience, design, manufacture, test, repair of indicating instruments, tube testers, a-c. and d-c. power instruments, special instruments, relays. Familiar with test, laboratory equipment. Good background for research or test. Also experience in production. Type of work secondary. Available at once. U.S., Canada. C-9585.

GRAD. E.E. 34, married, 13 yr. experience U.S.A., Europe, Latin America. Drafting, design, supt. of constr., elect. and mech., power plants, a-c. and d-c. substations, industrial electrifications, etc. Also some experience in design of elect. mach. Fluent Spanish. Will consider new field at reasonable salary. C-8553.

ENGG.-PRODUCTION demand close tie for efficiency. Has designed and regulated production in automatic devices, radio receivers, small motors. Also design field and factory high speed test equip. Familiar phonograph recording, vacuum tubes, lab. supervision, constr. E.E. degree, married, 30, locate New York vicinity. D-181.

RESEARCH, DEV. ENGR., 30, B.S. and E.E. Columbia and Harvard univ. 1 yr shop, 6 yr. test., research, development, patent experience on various electrical, electromechanical devices for domestic, industrial applications; proved and substantial record for original work. Engg. and sales promotion, good correspondent. Executive qualifications. A-1 character, personality. C-930.

TRAFFIC ENGR., grad. E.E., 12 yr. experience, pub. utility, municipal organizations in engineering, vehicular traffic control and fire alarm work. Thoroughly experienced, traffic surveys, planning, specifications, installation, etc. of traffic or fire alarm systems. Now completing traffic system in eastern city. Available immediately. B-9408.

ELECT. ENG., 33, married, B.S. E.E. 1921. 10 yr. automotive maintenance. G.E. Test. 3 yr. designing motors, generators, arc welding equipment. 3 yr. developing, designing automotive drive motors, generators, control. 3 yr. automotive development, maintenance bus, cab company. Interested, electrical, automotive, designing, maintenance. D-95.

GRAD. E.E., 46. 18 yr. experience in the manufacture of elect. wiring devices, incl. designing, development, test., estimating, cost and production work. 4 yr. with Underwriters Laboratories charge of branch office making inspections, tests, examinations and reports. Desires position with mfg. concern, inspection bureau or experimental laboratory. C-8449.

ELECT. ENGR., B.S. in E.E. 1928. 6 yr. operating experience in elect. pwr. plants, both hydro and stm., 4 yr. cost accounting, some test. and sales experience. Wishes position with elect. utility or mfg. concern. Single. Salary open. Location U.S. or foreign. C-7796.

# Membership

## Recommended for Transfer

The board of examiners, at its meeting of November 24, 1931, recommended the following Associates for transfer to the grade of Member. Any objection to these transfers should be filed at once with the national secretary.

### To Grade of Member

Board, Virgil Lee, vice-pres. and genl. supt., Pub. Serv. Co. of Colo., Denver
Brain, Vivian J.F., ch. elec. engr., Dept. of Pub. Wks., Sydney, N.S.W., Australia
Burt, Harvey A., asst. supt., hydro and trans., Pub. Serv. Co. of Colo., Denver, Colo.
Carlson, Victor H., asst. to elec. supt., Chile Exploration Co., Chile, S. A.
Carraway, Thomas W., Grinnell Co., Providence, R.I.
Cave, Jere Shunk, ch. engr., The Venezuela Telephone Co., Venezuela, S. A.
Dring, George S., div. plant supt., Am. Tel. & Tel. Co., Denver, Colo.
Fenkhausen, Rudolph H., supt., pwr. dept., Bethlehem Shipbuilding Corp., San Francisco, Calif.
Field, Russell M., section engr., Westinghouse Elec. & Mfg. Co., Sharon, Pa.
Hardaway, Warren D., supt., hydroelec. prod. and trans., Pub. Serv. Co. of Colorado, Denver
Hudson, Floyd E., asst. planning engr., Bangor Hydroelectric Co., Bangor, Me.
Kreul, Albert H., elec. maintenance and constr., Portland G. E. Co., Portland, Ore.
Nichols, Benjamin H., instructor, elec. engg., Oregon State College, Corvallis
Nolan, Thomas J., system operator, Toledo Edison Co., Toledo, Ohio
Rogers, Clarence E., ch. engr., Pacific Tel. & Tel. Co., Seattle, Wash.
Ryan, Richard M., elec. engr., G. E. Co., Kansas City, Mo.
Shirk, William B., steel mill engr., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
Siniapkin, Nicholas M., elec. engr., State Architect's Office, Albany, N.Y.
Smith, Walter F., Jr., member of tech. staff, Bell Tel. Lab., Inc., New York
Sterne, William C., pres., Arvada Electric Co., Denver, Colo.
Wang, Meng, prof. of E.E., Shansi Univ., China

## Applications for Election

Applications have been received by the secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the secretary before January 31, 1932.

January 1932

## Order Form for ELECTRICAL ENGINEERING Binding Service*

To the Order Dept., A.I.E.E.
33 W. 39th St., New York, N. Y.

Under separate cover I am forwarding prepaid ............................copies of ELECTRICAL ENGINEERING for 1931.
(How many?)

1. Please supply the following missing issues.................................................................................... @ 50 cents each. (Cost to non-member subscribers is $1 each.) (Name months desired)
2. I am enclosing ............................ in the amount of $.......... (Binding service alone is $3 delivered postpaid within the United States and its possessions; $4.25 postpaid to all other points.) (Check, draft, etc.)
3. Please ship prepaid to: (Please typewrite, or print carefully)

(Space for office use only)

............... copies received

............... copies supplied

@...............

Name.......................................................................................................

Street address.......................................................................................

City.............................................County.........................................

State..............................................Nation........................................

Signature.........................................................................Date...............

*(1) Wrap package securely; (2) place name and return address on it; (3) mail to address given above. If you do not use this form, give equivalent information in a letter. For other details see advertising section.

---

January 1932

## Order Form for Pamphlet Copies of A.I.E.E. Papers*

**All 1932 winter convention papers which are abstracted in this issue**

| Number | Author | Title |
|---|---|---|
| ☐ 32-4 | L. V. Bewley | Transient Oscillations of Mutually Coupled Windings |
| ☐ 32-5 | R. M. Baker | Equalizing Currents in the Armature of a D-C. Machine |
| ☐ 32-7 | D. A. Lightband | Temperature Rise of Ventilated Railway Motor Armatures |
| ☐ 32-8 | D. C. Prince | The Theory of Oil Blast Circuit Breakers |
| ☐ 32-9 | R. M. Spurck | The Practical Application of the Oil Blast Principle of Circuit Interruption |
| ☐ 32-10 | R. C. VanSickle and W. M. Leeds | Recent Developments in Arc Rupturing Devices |
| ☐ 32-11 | T. E. Browne, Jr. | Extinction of A-C. Arcs in Turbulent Gases |
| ☐ 32-12 | C. L. Dawes and A. F. Daniel | High Voltage Bridge for Measurements of Cables with Grounded Sheaths |
| ☐ 32-13 | W. B. Kouwenhoven and A. Banos, Jr | A High Sensitivity Power Factor Bridge |
| ☐ 32-14 | R. P. Siskind | Power Factor Measurements by the Capacitance Bridge |
| ☐ 32-15 | C. W. LaPierre | The Photoelectric Recorder |
| ☐ 32-16 | C. F. Harding and C. S. Sprague | Interconnection of Primary Lightning Arrester Ground and the Grounded Neutral of the Secondary Main |
| ☐ 32-17 | K. B. McEachron and L. Saxon | Field Studies of the Protection of Distribution Transformers by Lightning Arresters |
| ☐ 32-18 | A. M. Opsahl, A. S. Brookes, and R. N. Southgate | Protection of Distribution Transformers from Failure Due to Lightning |
| ☐ 32-19 | D. W. Roper | Studies in Lightning Protection on 4,000-Volt Circuits—III |
| ☐ 32-20 | H. A. Dambly, H. N. Ekvall, and H. S. Phelps | Distribution System Lightning Studies by Philadelphia Electric Co. |
| ☐ 32-21 | F. M. Starr | Equivalent Circuits |
| ☐ 32-22 | R. M. Foster | Geometrical Circuits of Electrical Networks |
| ☐ 32-23 | N. D. Kenney, A. M. Luery, and J. D. Moriaty | The Breakdown of Glass with Alternating Potentials |
| ☐ 32-24 | K. L. Scott | Relationships Among the Magnetic Properties of Magnet Steels and Permanent Magnets |
| ☐ 32-25 | R. A. Hentz and J. W. Jones | Experience with Electrical Stability of Conowingo Station of Philadelphia Electric Co. System |
| ☐ 32-26 | S. B. Griscom, W. A. Lewis, and W. R. Ellis | Generalized Stability Solution for Metropolitan Type Systems |
| ☐ 32-27 | A. G. Conrad and R. G. Warner | An Induction Motor with Paralleled Rotor and Stator |
| ☐ 32-28 | C. C. Shutt | Some Considerations in the Design of Damper Windings for Synchronous Motors |
| ☐ 32-30 | F. W. Godsey, Jr | Power Losses in Electrolytic Condensers |
| ☐ 32-31 | F. W. Godsey, Jr | Film Characteristics of Electrolytic Condensers |
| ☐ 32-32 | A. W. Simon and L. C. Kron | Electrical Precipitation |
| ☐ 32-33 | R. E. Hellmund and L. R. Ludwig | Commutation Considered as a Switching Problem |
| ☐ 32-34 | E. I. Pollard | Calculation of No-Load Damper Winding Loss in Synchronous Machines |
| ☐ 32-35 | L. P. Shildneck | Sine Wave Generators |
| ☐ 32-36 | J. C. Aydelott | Motors for 3,000-Volt D-C. Multiple Unit Cars |
| ☐ 32-37 | L. B. Curtis | Preparing Substations for Electric Operation |
| ☐ 32-38 | J. F. Hellweg | The Time Services of the U.S. Naval Observatory |
| ☐ 32-39 | G. W. Janson | Time Services of the Telegraph Companies |
| ☐ 32-40 | H. E. Warren | Synchronous Electric Time Service |
| ☐ 32-41 | F. Creedy, R.C.Lerch, P.W.Seal, and E.P.Sordon | Forces of Electric Origin in the Iron Arc |
| ☐ 32-42 | A. M. Candy | An Improved A-C. Arc Welder |
| ☐ 32-43 | K. L. Hansen | Recent Developments in Design of Arc Welding Generators |
| ☐ 32-44 | T. H. Haines and C. A. Corney | Investigation of Lightning Protection for Distribution Transformers |
| ☐ 32-45 | J. B. Whitehead and A. Banos, Jr | The Predetermination of the A-C. Behavior of Dielectrics |
| ☐ 32M1 | S. L. Goldsborough and W. A. Lewis | New High Speed Distance Relay with Impedance-Reactance Characteristic |
| ☐ 32M2 | H. K. Sels | Proposed Definition of Terms Used in Power System Studies |
| ☐ ........ | H. A. Affel, W. S. Gorton and R. W. Chesnut | New Key West-Havana Carrier Telephone Cable |
| ☐ ........ | W. C. Jones and A. H. Inglis | The Development of a Handset for Telephone Stations |
| ☐ ........ | R. E. Smith and L. A. Kelley | Carrier Application to a Telegraph Plant |
| ☐ ........ | G. S. Vernam | An Automatic Concentration Unit for Printing Telegraph Circuits |

**Papers presented prior to September 1931 and upon which articles in this issue are based**

| Number | Author | Title |
|---|---|---|
| ☐ 31-77 | B. M. Smith and C. Concordia | Core Loss Measurements at High Flux Densities |
| ☐ 31-117 | D. C. Jackson, Jr. | Application of the Cooperative Method of Instruction to Engineering Schools and Polytechnic Institutes |

*Members, Enrolled Students, and subscribers are entitled to one pamphlet copy of any paper in this list if requested within one year from above date. Thereafter a charge of 25 cents per copy will obtain.

*Address* Order Department A.I.E.E.
33 West 39th Street, New York, N. Y.

Name..............................................................

Street Address..................................................

City....................................State......................

# Officers and Committees for 1931-32

### President

C. E. SKINNER East Pittsburgh, Pa.
(*Term Expires July 31, 1932*)

### Junior Past-Presidents

HAROLD B. SMITH Princeton, Mass.
(*Term Expires July 31, 1932*)
W. S. LEE Charlotte, N.C.
(*Term Expires July 31, 1933*)

### Vice-Presidents

| Dist. No. | | |
|---|---|---|
| (1) | I. E. MOULTROP | Boston, Mass. |
| (3) | H. P. CHARLESWORTH | New York, N. Y. |
| (5) | T. N. LACY | Detroit, Mich. |
| (7) | G. C. SHAAD | Lawrence, Kans. |
| (9) | H. V. CARPENTER | Pullman, Wash. |
| | | (*Terms Expire July 31, 1932*) |
| (2) | W. B. KOUWENHOVEN | Baltimore, Md. |
| (4) | W. E. FREEMAN | Lexington, Ky. |
| (6) | P. H. PATTON | Omaha, Neb. |
| (8) | A. W. COPLEY | San Francisco, Cal. |
| (10) | L. B. CHUBBUCK | Hamilton, Ont., Can. |
| | | (*Terms Expire July 31, 1933*) |

### Directors

| | |
|---|---|
| J. ALLEN JOHNSON | Buffalo, N.Y. |
| A. M. MacCUTCHEON | Cleveland, O. |
| A. E. BETTIS | Kansas City, Mo. |
| | (*Terms Expire July 31, 1932*) |
| J. E. KEARNS | Chicago, Ill. |
| F. W. PEEK, Jr. | Pittsfield, Mass. |
| C. E. STEPHENS | New York, N.Y. |
| | (*Terms Expire July 31, 1933*) |
| A. B. COOPER | Toronto, Ont., Can. |
| A. E. KNOWLTON | New York, N.Y. |
| R. H. TAPSCOTT | New York, N.Y. |
| | (*Terms Expire July 31, 1934*) |
| L. W. CHUBB | East Pittsburgh, Pa. |
| B. D. HULL | Dallas, Texas |
| H. R. WOODROW | Brooklyn, N.Y. |
| | (*Terms Expire July 31, 1935*) |

### National Treasurer

W. I. SLICHTER New York, N.Y.
(*Term Expires July 31, 1932*)

### National Secretary

F. L. HUTCHINSON New York, N.Y.
(*Term Expires July 31, 1932*)

### General Counsel

Parker & Aaron
20 Exchange Place, New York, N.Y.

### Local Honorary Secretaries

T.J.Fleming, Calle B. Mitre 519, Buenos Aires, Argentina.
V.J.F.Brain, Dept. of Pub. Wks., Phillip St., Sydney, N.S.W., Australia.
F.M.Servos, Rio de Janeiro Tramways Lt. & Pr. Co., Rio de Janeiro, Brazil.
A.P.M.Fleming, Metropolitan Vickers Elec. Co., Trafford Park, Manchester, England.
A.S.Garfield, 173 Blvd. Haussmann, Paris (8e), France.
B.C.Battye, Punjab P.W.D., Hydroelectric Branch, Kapurthala House, Lahore, India.
Renzo Norsa, Via Caravaggio 1, Milano 25, Italy.
P.H.Powell, Canterbury College, Christchurch, New Zealand.
M.A.Chatelain, Polytechnical Institute, Apt. 27, Leningrad, Sosnowka 1-3, U.S.S.R.
A.F.Enstrom, Ingeniorsvetenskrapsakademien, Stockholm, 5, Sweden.
W.Elsdon-Dew, P.O. Box 4563, Johannesburg, Transvaal, Africa.

## GENERAL COMMITTEES

### Executive

C.E.Skinner, Chm., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
H.P.Charlesworth F.W.Peek, Jr.
J.Allen Johnson W.I.Slichter
W.S.Lee C.E.Stephens

### Board of Examiners

H.Goodwin, Jr., Chm., 801 Franklin Bldg., Philadelphia, Pa.
H.E.Farrer, Secy., 33 W. 39th St., New York, N.Y.
H.A.Currie R.H.Marriott
H.W.Drake L.W.W.Morrow
S.P.Grace A.L.Powell
H.A.Kidder W.R.Smith
F.V.Magalhaes R.H.Tapscott S.D.Sprong

### Finance

C.E.Stephens, Chm., Westingouse Elec. & Mfg. Co., 150 Broadway, New York, N.Y.
H.P.Charlesworth R.H.Tapscott

### Publication

E.B.Meyer, Chm., 80 Park Place, Newark, N.J.
F.A.Lewis, Secy., 33 W. 39th St., New York.
W.S.Gorsuch F.L.Hutchinson
W.H.Harrison H.R.Woodrow

### Technical Program

W.H.Harrison, Chm., Am. Tel. & Tel. Co., 195 Broadway, New York, N.Y.
C.S.Rich, Secy., 33 W. 39th St., New York, N.Y.
P.P.Alexander A.C.Cummins
P.L.Alger R.E.Doherty
Raymond Bailey C.W.Drake
J.R.Baker W.S.Gorsuch
R.A.Beekman W.B.Kouwenhoven
W.T.Blackwell Paul MacGahan
P.H.Brace E.L.Moreland
Vannevar Bush H.S.Osborne
H.P.Charlesworth D.E.Renshaw
P.H.Chase E.J.Rutan
L.W.Chubb D.W.Taylor
T.A.Worcester

### Sections

E.S.Lee, Chm., General Electric Co., Schenectady, N.Y.
W.B.Kouwenhoven I.M.Stein
G.H.Quermann W.H.Timbie
*Ex-officio:*
Chairmen of all Institute Local Sections.

### Membership

R.L.Kirk, Chm., Duquesne Lt. Co., Pgh., Pa.
E.P.Coles J.Allen Johnson
F.G.Graf C.H.Kline
James Harrison J.A.Koontz
Joseph Hellenthal T.G.LeClair
V.L.Hollister E.M.Wood I.M.Stein
*Ex-officio:*
Chairmen of Section membership committees.

### Constitution and By-Laws

W.S.Gorsuch, Chm., 600 W. 59th St., New York.
C.O.Bickelhaupt E.B.Meyer
H.A.Kidder W.I.Slichter

### Coordination of Institute Activities

H.P.Charlesworth, Chm., 463 West St., New York.
W.S.Gorsuch E.S.Lee
W.H.Harrison E.B.Meyer
F.L.Hutchinson C.E.Stephens

### Student Branches

W.H.Timbie, Chm., Massachusetts Institute of Technology, Cambridge, Mass.
W.E.Freeman C.F.Scott
F.C.McMillan W.J.Seeley
*Ex-officio:*
All Student Branch Counselors.

### Headquarters

R.H.Tapscott, Chm., New York Edison Co., 4 Irving Place, New York, N.Y.
F.L.Hutchinson C.E.Stephens

### Public Policy

Bancroft Gherardi, Chm., Am. Tel. & Tel. Co., 195 Broadway, New York, N.Y.
C.C.Chesney Farley Osgood
F.B.Jewett H.J.Ryan
W.S.Lee R.F.Schuchardt

### Standards

A.M.MacCutcheon, Chm., Reliance Elect. & Engg. Co., 1088 Ivanhoe Rd., Cleveland, O.
H.E.Farrer, Secy., 33 W. 39th St., New York
A.B.Cooper V.M.Montsinger
J.E.Goodale F.D.Newbury
C.R.Harte E.B.Paxton
J.F.Meyer W.I.Slichter
*Ex-officio:*
Chairmen of working committees.
Chairmen of A.I.E.E. delegations and representatives on other standardizing bodies.
President of U.S. National Committee of I.E.C.

### Edison Medal

*Appointed by the President for term of five years.*
H.P.Charlesworth P.M.Lincoln C.E.Stephens
(*Terms expire July 31, 1932*)
D.C.Jackson, Chm. C.F.Harding F.A.Scheffler
(*Terms expire July 31, 1933*)
L.W.W.Morrow W.S.Rugg R.F.Schuchardt
(*Terms expire July 31, 1934*)
C.I.Burkholder F.A.Gaby H.J.Ryan
(*Terms expire July 31, 1935*)
H.H.Barnes, Jr. E.B.Meyer P.H.Thomas
(*Terms expire July 31, 1936*)
*Appointed by the Board of Directors from its own membership for term of two years:*
A.E.Knowlton H.B.Smith R.H.Tapscott
*Terms expire July 31, 1932*)
J.E.Kearns W.S.Lee F.W.Peek, Jr.
(*Terms expire July 31, 1933*)
*Ex-officio:*
C.E.Skinner, President
W.I.Slichter, National Treasurer
F.L.Hutchinson, National Secretary
(*Terms expire July 31, 1932*)

### Lamme Medal

C.C.Chesney, Chm.
H.P.Charlesworth R.B.Williamson
(*Terms expire July 31, 1932*)
R.D.Mershon J.C.Smith P.H.Thomas
(*Terms expire July 31, 1933*)
A.M.Dudley P.M.Lincoln J.C.Parker
(*Terms expire July 31, 1934*)

### Principles of Professional Conduct

R.F.Schuchardt, Chm., 72 W.Adams St., Chicago.
A.H.Babcock W.E.Mitchell
G.Faccioli C.E.Stephens
F.B.Jewett J.B.Whitehead

### Award of Institute Prizes

W.H.Harrison, Chm., Am. Tel. & Tel. Co., 195 Broadway, New York, N.Y.
L.W.Chubb A.E.Knowlton E.B.Meyer

### Safety Codes

J.C.Forsyth, Chm., N.Y. Board of Fire Underwriters, 85 John St., New York, N.Y.
A.W.Berresford Wills Maclachlan
L.B.Chubbuck F.V.Magalhaes
J.F.Fairman J.D.Noyes
H.B.Gear F.A.Pattison
F.D.Knight Frank Thornton
M.G.Lloyd H.S.Warren

### Columbia University Scholarships

W.I.Slichter, Chm., Columbia Univ., New York
Francis Blossom H.C.Carpenter

### Legislation Affecting Engg. Profession

H.A.Kidder, Chm., 600 W. 59 St., New York.
James P.Alexander
T.F.Barton
B.M.Brigman
H.P.Charlesworth
L.F.Leurey
L.W.W.Morrow
J.C.Parker
J.R.Price
Herbert S.Sands
M.R.Scharff
H.H.Schoolfield
W.I.Slichter
J.B.Thomas

### Economic Status of the Engineer

C.O.Bickelhaupt, Chm., Am. Tel. & Tel. Co., 195 Broadway, New York, N.Y.
W.S.Lee
E.W.Rice, Jr.
W.S.Rugg
C.F.Scott

### Iwadare Foundation, Japan

F.B.Jewett, Chm., 195 Broadway, New York.
W.I.Slichter
Gerard Swope

### N.Y. Museum of Science and Industry

J.P.Jackson, Chm., N.Y. Edison Co., 4 Irving Place, New York, N.Y.
C.O.Bickelhaupt
R.H.Nexsen

### Popular Science Award

F.W.Peek, Jr., Chm., General Electric Co., Pittsfield, Mass.
W.H.Harrison
C.E.Stephens

## TECHNICAL COMMITTEES

### Automatic Stations

D.W.Taylor, Chm., United Engineers & Constructors, Inc., 80 Park Place, Newark, N.J.
F.F.Ambuhl
A.E.Anderson
L.D.Bale
C.F.Craig
John Fies
A.M.Garrett
Joseph Hellenthal
C.A.Mayo
I.E.Moultrop
M.E.Reagan
O.J.Rotty
Garland Stamper
L.J.Turley
F.Zogbaum

### Communication

H.S.Osborne, Chm.
E.J.O'Connell, Secy.
Am. Tel. & Tel. Co., 195 Broadway, New York.
H.M.Bascom
E.L.Bowles
W.H.Capen
A.A.Clokey
R.N.Conwell
C.F.Craig
B.R.Cummings
R.D.Evans
I.C.Forshee
D.H.Gage
B.D.Hull
T.Johnson, Jr.
G.M.Keenan
G.A.Kositzky
C.J.Larsen
John Mills
J.W.Milnor
C.W.Mitchell
F.A.Raymond
H.A.Shepard
E.R.Shute
A.L.Stadermann
C.H.Taylor
H.M.Turner
F.A.Wolff

### Education

R.E.Doherty, Chm., Dunham Laboratory, 10 Hillhouse Ave., New Haven, Conn.
R.W.Adams
M.W.Alexander
E.W.Allen
J.W.Barker
Edward Bennett
P.S.Biegler
H.V.Carpenter

## Geographical District Executive Committees

| District | (Chairman (Vice-President, A.I.E.E.) | Secretary (District Secretary) |
|---|---|---|
| No. 1—North Eastern | I. E. Moultrop, Edison Elec. Illum. Co., 39 Boylston St., Boston, Mass. | A. C. Stevens, General Electric Co., Schenectady, N. Y. |
| No. 2—Middle Eastern | W. B. Kouwenhoven, Johns Hopkins University, Baltimore, Md. | G. S. Diehl, Pennsylvania Water & Power Co., 1611 Lexington Building, Baltimore, Md. |
| No. 3—New York City | H. P. Charlesworth, 463 West St., New York, N. Y. | C. R. Jones, Westinghouse E. & M. Co., 150 Broadway, New York, N. Y. |
| No. 4—Southern | W. E. Freeman, University of Kentucky, Lexington, Ky. | E. A. Bureau, University of Kentucky, Lexington, Ky. |
| No. 5—Great Lakes | T. N. Lacy, Mich. Bell Tel. Co., 1365 Cass Ave., Detroit, Mich. | A. G. Dewars, No. States Pr. Co., 15 S. 15th St., Minneapolis, Minn. |
| No. 6—North Central | P. H. Patton, Northwestern Bell Tel. Co., Telephone Building, Omaha, Neb. | M. S. Coover, University of Colorado, Boulder, Colo. |
| No. 7—South West | G. C. Shaad, University of Kansas, Lawrence, Kans. | R. W. Warner, University of Kansas, Lawrence, Kans. |
| No. 8—Pacific | A. W. Copley, Westinghouse Elec. & Mfg. Co., 1 Montgomery St., San Francisco, Calif. | C. E. Baugh, 245 Market St., San Francisco, Calif. |
| No. 9—North West | H. V. Carpenter, State College of Wash., Pullman, Wash. | R. D. Sloan, State College of Washington, Pullman, Wash. |
| No. 10—Canada | L. B. Chubbuck, Canadian Westinghouse Co., Hamilton, Ont. | W. L. Amos, Hydro-Elec. Pr. Comm., 190 University Ave., Toronto, Ont. |

Note: Each district executive committee includes the chairmen and secretaries of all Sections within the district and the chairman of the district committee on student activities.

## Local Sections of the Institute

| Name | District | Chairman | Secretary | Secretary's Address |
|---|---|---|---|---|
| Akron | 2 | R. R. Krammes | R. A. Hudson | Goodyear Zeppelin Corp., Akron, Ohio |
| Atlanta | 4 | A. G. Stanford | J. H. Persons | General Electric Co., Atlanta, Ga. |
| Baltimore | 2 | K. A. Hawley | J. Wells | Western Electric Co., Baltimore, Md. |
| Birmingham | 4 |  | O. E. Charlton | Allied Engineers, Inc., Birmingham, Ala. |
| Boston | 1 | C. A. Corney | G. J. Crowdes | Simplex Wire & Cable Co., Cambridge, Mass. |
| Chicago | 5 | F. R. Innes | E. C. Williams | 20 North Wacker Drive, Chicago, Ill. |

# Local Sections of the Institute—Continued

| Name | District | Chairman | Secretary | Secretary's Address |
|---|---|---|---|---|
| Cincinnati | 2 | E. S. Fields | J. A. Noertker | Cincinnati Street Railway Co., Cincinnati, Ohio |
| Cleveland | 2 | G. A. Kositzky | F. E. Snell | Cleveland Railway Co., Cleveland, Ohio |
| Columbus | 2 | W. L. Everitt | Roy Mallory | Ohio Bell Tel. Co., Columbus, Ohio |
| Connecticut | 1 | R. G. Warner | W. B. Hall | Yale University, New Haven, Conn. |
| Dallas | 7 | Gibbs A. Dyer | S. M. Sharp | 1100 Allen Bldg., Dallas, Tex. |
| Denver | 6 | R. E. Nyswander | N. R. Love | 807 Tramway Bldg., Denver, Colo. |
| Detroit-Ann Arbor | 5 | J. J. Shoemaker | O. E. Hauser | Detroit Edison Co., Detroit, Mich. |
| Erie | 2 | P. R. Urich | C. V. Roberts | Erie Lighting Co., 21-23 West 10th St., Erie, Pa. |
| Florida | 4 | Joseph Weil | R. P. Smith | P. O. Box 2574, Jacksonville, Fla. |
| Fort Wayne | 5 | E. J. Schaefer | C. M. Summers | General Elec. Co., Fort Wayne, Ind. |
| Houston | 7 | E. M. Wise | J. S. Waters | Rice Institute, Houston, Texas |
| Indianapolis-Laf | 5 | E. L. Carter | E. G. Thoms | Indiana Bell Tel. Co., Indianapolis, Ind. |
| Iowa | 5 | H. B. Hoffhaus | Leon F. Wood | Telephone Bldg., 9th & High Sts., Des Moines, Iowa |
| Ithaca | 1 | W. E. Meserve | B. K. Northrop | Cornell Univ., Ithaca, N. Y. |
| Kansas City | 7 | George Fiske | R. M. Ryan | General Electric Co., Kansas City, Mo. |
| Lehigh Valley | 2 | Morland King | J. H. Diefenderfer | Penna. Pr. & Lt. Co., Hazleton, Pa. |
| Los Angeles | 8 | P. S. Biegler | F. E. Dellinger | Los Angeles Gas & Elec. Corp., Los Angeles, Calif. |
| Louisville | 4 | P. P. Ash | C. M. Ewing | Louisville Gas & Elec. Co., Louisville, Ky. |
| Lynn | 1 | J. A. Cook | G. R. Sturtevant | General Electric Co., West Lynn, Mass. |
| Madison | 5 | N. H. Blume | G. F. Tracy | University of Wisconsin, Madison, Wis. |
| Memphis | 4 | W. A. Gentry | F. L. Christenbury | Memphis Power & Light Co., Memphis, Tenn. |
| Mexico | 3 | E. F. Lopez | L. Castro, Jr | Dept. Elect. y Teleg., Ferrocarriles Nacionales de Mex., Mexico, D.F. |
| Milwaukee | 5 | C. H. Krueger | E. U. Lassen | Cutler Hammer, Inc., Milwaukee, Wis. |
| Minnesota | 5 | Oscar Gaarden | E. H. Hagensick | The Pyle-National Co., St. Paul, Minn. |
| Montana | 9 | J. A. Thaler | H. Dale Cline | 312 So. 6th Ave., Bozeman, Mont. |
| Nebraska | 6 | A. L. Turner | C. Talsma | 610 Electric Building, Omaha, Nebraska |
| New York | 3 | O. H. Caldwell | H. C. Dean | N. Y. & Queens Elec. Lt. & Pr. Co., Flushing, N. Y. |
| Niagara Frontier | 1 | R. W. Graham | G. W. Eighmy | General Electric Co., 1100 Electric Bldg., Buffalo, N. Y. |
| North Carolina | 4 | J. E. Lear | R. F. Stainback | Box 1029, Chapel Hill, N. C. |
| Oklahoma City | 7 | C. T. Almquist | C. E. Bathe | Oklahoma Gas & Elec. Co., Oklahoma City, Okla. |
| Philadelphia | 2 | C. N. Johnson | J. L. MacBurney | Elec. Storage Battery Co., Philadelphia, Pa. |
| Pittsburgh | 2 | F. A. Conner | T. Spooner | Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa. |
| Pittsfield | 1 | F. R. Finch | K. R. Van Tassel | General Electric Co., Pittsfield, Mass. |
| Portland, Ore. | 9 | R. J. Davidson | F. M. Lewis | Northwestern Electric Co., Public Serv. Bldg., Portland, Ore. |
| Providence | 1 | W. S. Maddocks | O. W. Briden | Blackstone Valley Gas & Elec. Co., Pawtucket, R. I. |
| Rochester | 1 | F. C. Young | E. K. Huntington | Rochester Gas & Elec. Corp., Rochester, N. Y. |
| St. Louis | 7 | C. H. Kraft | C. H. Lankford | Century Electric Co., 1806 Pine St., St. Louis, Mo. |
| San Antonio | 7 | J. E. Woods | D. E. Woods | P. O. Box 1105, San Antonio, Texas |
| San Francisco | 8 | E. A. Crellin | W. C. Smith | 872 Russ Bldg., San Francisco, Calif. |
| Saskatchewan | 10 | N. W. Dubois | A. B. Coward | Light & Power Dept., Regina, Sask., Can. |
| Schenectady | 1 | R. A. Beekman | E. P. Nelson | General Electric Co., Schenectady, N. Y. |
| Seattle | 9 | M. T. Crawford | C. B. Carpenter | 836 Dexter Horton Bldg., Seattle, Wash. |
| Sharon | 2 | R. M. Field | A. M. Wiggins | Westinghouse E. & M. Co., Sharon, Pa. |
| Southern Virginia | 4 | J. H. Berry | E. L. Lockwood | Virginia Public Service Co., Newport News, Va. |
| Spokane | 9 | F. L. Vincent | W. M. Allen | Home Tel. & Tel. Co., Spokane, Wash. |
| Springfield, Mass | 1 | B. V. K. French | L. C. Packer | Westinghouse Elec. & Mfg. Co., Springfield, Mass. |
| Syracuse | 1 | C. W. Henderson | W. E. Mueller | Denison & Thompson, Syracuse, N. Y. |
| Toledo | 2 | J. A. Dinwiddie | Max Neuber | 1257 Fernwood Ave., Toledo, Ohio |
| Toronto | 10 | T. W. Eadie | G. D. Floyd | Hydro Elec. Pr. Comm., 190 Univ. Ave., Toronto, Ont. |
| Urbana | 5 | E. H. Waldo | E. A. Reid | University of Illinois, Urbana, Ill. |
| Utah | 9 | Paul Ransom | A. L. Taylor | Univ. of Utah, Salt Lake City, Utah |
| Vancouver | 10 | G. R. Wright | C. Arnott | B. C. Elec. Railway Co., Ltd., Vancouver, B. C., Canada |
| Washington | 2 | G. L. Weller | C. M. Brown | Westinghouse Elec. & Mfg. Co., Washington, D. C. |
| Worcester | 1 | J. P. McCann | R. P. Bullen | General Electric Co., Worcester, Mass. |
| Total 60 | | | | |

# Student Branches of the Institute

# Engineering Literature

## New Books

### In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during November are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

KINEMATICS OF MACHINERY. By C. D. Albert and F. S. Rogers. N. Y., John Wiley & Sons, 1931. 527 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.50.——This textbook is based upon the course given to engineering students at Cornell University but contains advanced material, in addition to that included in most courses, upon velocity and acceleration vector diagrams, cams, and spur gears. The treatment is concise, yet thorough, and many problems are included.

PRINCIPLES OF DIRECT-CURRENT MACHINES. By A. S. Langsdorf. 4th ed., N. Y. & London, McGraw-Hill Book Co., 1931. 586 pp., illus., diagrs., charts, tables, 8 x 6 in., cloth, $4.50.——This well-known text aims to supply a reasonably complete treatment of the fundamental principles that underly the design and operation of all types of d-c. machinery. This edition has been extensively rewritten, and new material has been added to bring it abreast of modern practise.

RADIO FREQUENCY ELECTRICAL MEASUREMENTS. By Hugh A. Brown. N. Y. & London, McGraw-Hill Book Co., 1931. 386 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.——The fundamentals of the standard methods are presented together with some of the recent advances in this field. The theory and principles are explained, the necessary steps in the laboratory procedure or manipulation are described, and the precision attainable, the precautions, and the general merits of the methods are discussed. The book is intended for students of radio communication and electrical measurements and also is designed to serve as a manual for the radio engineer.

THEORIE DER THERMISCHEN MESSGERATE DER ELEKTROTECHNIK, Grundlagen zu ihrer Berechnung. By J. Fischer. Stuttgart, Ferdinand Enke Verlag, 1931. 147 pp., diagrs., charts, tables, 10 x 7 in., paper, 13 RM.——Presents in systematic form the theoretical principles underlying hot-wire instruments, thermocouples, bolometers, and similar instruments, and summarizes the results of research upon the question of heat transfer. This knowledge is then used to discuss the theory of the various types of instruments. The book supplies the designer with the fundamental data that he needs.

PRINCIPLES OF ELECTRICAL ENGINEERING. By G. C. Blalock. N. Y., McGraw-Hill Book Co., 1931. 498 pp., illus., diagrs., charts, tables, 9 x 6 in., cloth, $4.00.——A concise course in the fundamentals, with frequent references to practical applications. The text is intended primarily for students of civil, chemical, or mechanical engineering but may also be used by students of electrical engineering as an introduction to the subject.

RADIO RECEIVING TUBES. By J. A. Moyer and J. F. Wostrel. 2nd ed. N. Y., McGraw-Hill Book Co., 1931. 323 pp., illus., diagrs., charts, tables, 8 x 5 in., cloth, $2.50.——The essential principles underlying the operation of vacuum tubes are explained in simple, non-technical fashion in this book, which will meet the needs of the average student of radio communication. The construction, action, reactivation and testing of vacuum tubes are described, and their uses as detectors, amplifiers and oscillation generators explained. A chapter is devoted to specifications, and another to the applications of vacuum tubes to other industrial uses than radio transmission and reception.

SCIENCE IN ACTION. By E. R. Weidlein and W. A. Hamor. N. Y., McGraw-Hill Book Co., 1931. 310 pp., illus., tables, 9 x 6 in., cloth, $3.00.——This book gives a readable account of the methods by which scientific investigation has been applied to the problems of manufacturing, and of what has been accomplished by it. The history of industrial research is outlined, and some major achievements in promoting human welfare, in creating new industries, in preventing waste, and in improving social conditions are set forth. Suggestions for the organization of research work and the selection of workers are given.

A.S.T.M. TENTATIVE STANDARDS 1931. Philadelphia, Am. Soc. for Testing Mtl. 1008 p., 9x6 in., cloth, $8; paper, $7.——Tentative specifications, methods of test, and recommended practises which had been proposed to the association, but had not been formally adopted in September, 1931. 180 standards are given, 42 of which appear for the first time.

CONVERSION EQUIVALENTS IN INTERNATIONAL TRADE. By S. Naft. Philadelphia, Comm'l Museum, 1931. 357 p., 9x6 in., cloth, $5.——An unusually comprehensive collection of weights and measures. Factors and tables for converting the units of all countries are given in more than usual detail; tabulated alphabetically and geographically, as well as by systems. Attention is paid to compound conversions and to special measures used in engineering, commerce and various industries.

DIESEL REFERENCE GUIDE. By J. Rosbloom. Jersey City, N. J., Industrial Institute, Inc., 1931. 292 p., 10x8 in., cloth, $10.——Intended as a reference work for diesel engine owners, manufacturers and operators; brings together in convenient form such practical information as: theory and construction of the engines, their installation and management, accessories, fuels, repairing, descriptions of locomotive, airplane, and automobile engines. Diesel engine installations in America are listed.

ECONOMIC CONTROL OF QUALITY OF MANUFACTURED PRODUCT. By W. A. Shewhart. N. Y., D. Van Nostrand Co., 1931. 501 p., 9x6 in., cloth, $6.50.——An important work upon the use of statistical methods in the study of the problem of controlling the quality of manufactured articles. Using as an illustration the experience of the Bell Telephone Laboratories in developing the most efficient ways of applying these methods to the problems that arise in manufacturing, he explains clearly the mathematical and statistical principles that are involved, and shows how they are applied to actual problems.

### ENGINEERING SOCIETIES LIBRARY

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Selected Items From Current Literature

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 2,000 technical periodicals are given in the following columns. All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page, or make translations of foreign articles at cost.

### CABLES

**Rubber Insulated.** New Control Cables Have Improved Characteristics, H.M.Friend. *Power*, v 74, Nov 10, '31, p 666-9. Developments made in insulated wire and cable based on recent discoveries by rubber chemists and physicists and experimental research work of cable manufacturers in applying these discoveries; results of tests on rubber insulated cable.

**Telephone.** Placing of Aerial Cables by Suspension, R.Blain. *Telephone Engr.*, v 35, Oct '31, p 25-7. Importance of placing messenger at proper tension in aerial cable construction is explained; construction and use of tension indicator.

**Underground—Manholes.** Steel Forms for Concrete Manholes Show Economies, A.J.Batchelor. *Elec. World*, v 98, Oct 31, '31, p 777. $27.10 saving per job on labor alone is realized by Toledo Edison Co. through use of steel forms for building concrete underground system manholes; in the year since these forms were adopted company has used them eight times.

### CIRCUIT BREAKERS

**Oil.** The Impulse High-speed Circuit Breaker, W.K.Rankin. *Gen. Elec. Rev.*, v 34, Oct '31, p 553-8. Initially developed for 25-cycle railway use; serviceable also for 60-cycle distribution; design based on new theory of current interruption; arc-quenching oil-blast produced mechanically; description of operation of mechanism and electrical performance.

### CLOCKS

**Electric.** Electric Clocks, S.F.Philpott. *Elec. Rev.*, v 109, Oct 23, '31, p 626-7. Consideration of relative advantages of various types available.

### CRANES

**Electric.** New Type Crane and Hoist, G.A. Caldwell. *Elec. World*, v 98, Oct 17, '31, p 692-5. Motor-generator set used as exciter for main a-c. crane or hoist motor to give dynamic control in lowering operations; principles used and description of application; practise illustrated on Brooklyn installation; speed-torque curves.

### DUST PRECIPITATION

**Electric.** Selecting Equipment for Electrostatic Precipitation, R.H.Kaufmann. *Chem. and Met. Eng.*, v 38, Oct '31, p 570-2. Development of applications of Cottrell process; precipitation treater for recovery of sulphuric-acid mist; how high-voltage d-c. supply for treater operation can be obtained; removal of tar and residues from gases in precipitation treater.

### DYNAMOMETER

**Electric.** Electric Dynamometers for Production Testing, F.W.Highfield. *Machy.*, v 39, Oct 1, '31, p 12-7. Operating principles and appl. with particular regard to testing of internal combustion engines. Before Instn. Production Engrs.

### ELECTRIC DRIVE

Individual Drives Simplify Roll-Table Operation, W.B.Snyder. *Elec. World*, v 98, Oct. 10, '31, p 650-2. Conveyor tables with motor on each roll have had their greatest development and application in steel industry; but reduced maintenance, ease of control, and quiet operation should fit it into any industry where materials of suitable length are handled in processes of manufacture.

**Industrial Plants.** Electric Drive in Factories, W.P.Conly. *Elec. Rev.*, v 109, Oct 9, '31, p 527-8. Comparison with crude-oil engine; some data regarding consumption of electricity per hp. installed in different trades; results of analysis for various types of plants given in tables.

**Pumps.** Control of Synchronous Motor Pump Drives, R.C.Allen. *Maintenance Eng.*, v 89, Sept '31, p 462-5. Factors to be considered in appl. of synchronous motor to pump drive; control equipment; advantages of increased efficiency, and better power factor weighed against complexity of operation.

### ELECTRIC MACHINERY

**Testing.** Losses in D-C Machines from No-Load Tests, R.G.Isaacs. *Instn. Elec. Engrs.—Jl.*, v 69, Oct '31, p 1303-8. Determination of rotational losses of dynamos and motors that occur on load, by means of no-load test which allows for increase of iron losses due to load; theory of test and method of carrying it out; typical results show probable accuracy of method.

### ELECTRIC MEASURING

**Instruments.** Electroscope Capacity Balance, W.O.Bayliss. *Australasian Elec Times*, v 10, Sept 28, '31, p 368-70. Apparatus developed by E.B.Brown exhibited at Melbourne Univ. Eng. School enables determination to be carried out very much more rapidly than, and quite as accurately as, usual methods.

### ELECTROMAGNETS

Design and Construction of an Electromagnet for Investigation, E.J.Shaw. *Rev. Sci. Instruments*, v 2, Oct '31, p 611-7. Familiar du Bois type of magnet was not particularly suited for number of investigations of magnetic properties of atoms and molecules performed in laboratory of Univ. of Ill.; special type of electromagnet designed shows four outstanding features over type mentioned.

### ELEVATORS

**Control.** Pliotron Tubes Level Elevators in McGraw-Hill Building. *Power*, v 74, Nov 3, '31, p 632-5. In new 33-story McGraw-Hill Building are 9 passenger and 5 freight elevators equipped with Pliotron leveling devices; elementary connection diagram of Pliotron elevator control system.

**Door Operation.** How Hoistway Door Operation Affects Elevator Service, H.B.Cook. *Power*, v 74, Oct '31, p 608-9. Method for determining force necessary for opening and closing different types of elevator hoistway doors and what effect increasing time of operation has on door mechanism.

### ENGINEERS

**Employment.** How Many Engineers Are Now Unemployed? H.M.Friend. *Power*, v 74, Oct 27, '31, p 600-4. Analysis of survey based on Engg. Societies Empl. Service and various state and government agencies; registrations and placements per 1,000 members of 1927 to 1931.

### FEEDWATER

**Treatment.** Solubility of Calcium Salts in Boiler Water, F.G.Straub. *A.S.M.E.—Advance Paper* for mtg. Nov 30-Dec 4, '31, 6 p. Purpose of investigation to determine behavior at elevated temperatures of various chemical compounds found in boiler waters.

### FURNACES

**Arc.** Twenty Year Advance in Electric Arc Furnaces, W.E.Moore. *Heat Treating and Forging*, v 17, Oct '31, p 982-7. Paper before Electrochem. Soc. previously indexed from their preprint, no 60-11 for mtg. Sept. 2-5, 1931.

**Industrial.** Industrial Gas and Electric Furnaces, E.Gossow. *Eng. Progress*, v 12, Oct '31, p 217-22. Operating characteristics and classification of industrial furnaces; furnace atmosphere; gas furnace, fuel gases, burners; examples of large industrial installations.

**Melting.** The Manufacture of Acid Electric Steel and Cast Iron, H.H.Walther. *Iron and Steel Engr.*, v 8, Oct '31, p 415-22. Practical features involved in successful economical operation of electric furnaces of 3-ton per hr. capacity, direct arc, 3-phase; electric furnace costs covering 4-week period.

### GATES

**Hydraulic Ellipsoid.** Lightness and Low Costs Obtained by New Penstock Gate Design, A.J.Ackerman. *Eng. News-Rec.*, v 107, Oct 15, '31, p 600-4. Design and fabrication of ellipsoid, nearly all welded, emergency gate, 16 ft.in diam., for pressure tunnel at Calderwood dam in Tennessee; maximum head of 260 ft. was assumed; special tests of restrained plates.

### HYDROELECTRIC

**Power Irrigation.** Hydro Power Provides Revenue for Irrigation Works, H.A.Brown. *Power*, v 74, Nov 10, '31, p 663-5. By combining power development with irrigation dams possible to pay project's construction costs from power sales.

### INSULATING MATERIALS

**Specifications.** Methods of Test Relating to Electrical Insulating Materials. *A.S.T.M.—Report Committee* D-9, '31, 212 p. Compilation of standards and tentative standards, together with annual report of committee.

### LAMPS

**Arc.** Construction and Operation of Capillary Mercury Arcs, R.H.Crist. *Optical Soc. America—Jl.*, v 21, Oct '31, p 690-7. Nature of problem and experimental development; nature of deposit; character of emission; curves.

**Glow.** A Cold-Cathode 110-Volt Gaseous Illuminant. *Electronics*, v 3, Oct '31, p 140-1. Two forms of Spanner Germer-Doring gaseous lamp adapted for operation in standard lamp socket for 110 volts a-c. or d-c.

### LIGHTING

**Airplane.** Lights for Airplanes, R.W.Cost. *Elec. Jl.*, v 28, Oct '31, p 573-5. Equipment and its installation; notes on incandescent lamps; navigation; instrument board lights; cabin lights; landing lights; lighting circuits.

**Airport.** The Detroit City Airport Anticipates Night Flying, H.K.Flint. *Elec. Jl.*, v 28, Oct '31, p 566-7. More than 50 floodlights, each producing beam intensity of about 10,000,000 candle-power, furnish illumination for night movements of airplanes at Detroit City Airport.

**Fog.** Transmission of Light Through Fog, F.C.Breckenridge. *Aircraft Eng.*, v 3, Oct '31, p 261-4. Attempt to correlate results of fog-chamber investigations by C.L.Utterback, S.H. Anderson, and H.G.Houghton, and with natural fog by E.Farrer, E.P.T.Tyndall, F.Benford, L.P.Granath and E.O.Hulburt; particle sizes; formation of haze particles. Before Int. Illum. Congress.

**Houses.** Your Lights at Home, M.A.Sheppard. *Elec. Jl.*, v 28, Oct '31, p 553-6. Rich market lies before electrical industry; best attack is probably encouraging those in industry to have their own homes adequately lighted; lights must be integral part of home furnishings rather than afterthought.

**Street.** Modern Street Lighting Practise, L.A.S.Woods. *Elec. Jl.*, v 28, Oct '31, p 557-9. Modern city plans its street lighting from investigation of requirements for each locality; outstanding examples of such comprehensive street-lighting plans are cities of Milwaukee and St. Louis. Before Int. Commission of Illum.

**Street Cutouts.** Series Street Lamp Has Inbuilt Cutout. *Elec. Jl.*, v 28, Oct '31, p 570. Novel idea of using one of best conductors, copper, for insulator is basis of new inbuilt cutout for series lamps; copper particles are covered with insulating film, which breaks down at lamp failure, allowing copper to fuse and reestablish circuit.

### LOUD SPEAKERS

**Diaphragms.** Behaviour of Conical Diaphragms used in Acoustic Apparatus for Reproduction of Speech and Music, N.W.McLachlan and G.A.V.Sowter. *Lond., Edinburgh and Dublin Philosophical Mag. and Jl. Science*, v 12, Oct '31, p 771-815. Conical Diaphragms with free edge, with reinforced edge and with rubber surround; comparison of three preceding cases; modes of diaphragm corresponding to upper frequency resonances; influence of coil mass, etc.

**Horns.** Indoor Applications of Air-Column Horns, C.J.Brown. *Projection Eng.*, v 3, Oct '31, p 15-6. Type of horn to be used under given conditions is described and illustrated.

### MAGNETISM

Temperature Variation of Intrinsic Magnetization and Associated Properties of Ferromagnetics, E.C.Stoner. *Lond., Edinburgh and Dublin Philosophical Mag. and Jl. Science*, v 12, Oct. '31, p 737-63. Relation of intrinsic magnetization to other properties of ferromagnetics is briefly discussed, and evidence for regarding ferromagnetism at ordinary temperatures as due to interchange interaction of electron spins is summarized. Bibliography.

New Theory of Magnetic Storms—I—Initial Phase, S.Chapman and V.C.A.Ferraro. *Terrestrial Magnetism and Atmospheric Electricity*, v 36, June '31, p 77-97 and Sept p 171-86. Motion of infinite plane-slab stream, cylindrical stream and neutral ionized system of any form in uniform magnetic field; internal steady motion of neutral ionized stream in non-uniform magnetic field; phenomena accompanying advance of solar ionized stream into earth's field.

### MANHOLES

**Standardization.** Simplification and Standardization of Manhole Frames and Covers, L.B. Fish. *ASA Bul.*, Sept '31, p 26-8. Progress reports of sectional committee of ASA Telephone Group and A.S. of C.E.; types and sizes reduced; simplification of materials.

### MANOMETERS

**Vacuum Tube.** Measuring One Trillionth of an Atmosphere, E. K. Jaycox, *Bell Lab. Rec.*, v 10, Oct '31, p 34-8. In making studies of phenomena requiring high degree of vacuum, it is important that physicists have knowledge of degree of pressure within apparatus; ionization manometer for accomplishing this was invented by O.E.Buckley in 1916; ionization manometer for this purpose of new design has been recently developed by H.W.Weinhart and author.

### MICROPHONES

**Moving Coil.** A Moving Coil Microphone for High Quality Sound Reproduction, W.C.Jones and L.W.Giles. *Projection Eng.*, v 3, Oct '31, p 10-2. Microphone described is more efficient than conventional form of condenser microphone and its transmission characteristics are unaffected by changes in temperature, humidity and barometric pressure.

### MOTORS

**Commutator.** Alternating-current Commutator Motors. *Engineering*, v 132, Oct 30, '31, p 559-60. 90-hp., 220-volt, 3-phase machine, built by Holmes for abnormal range of 12.5 to 1, has speed range of from 375 to 30 r.p.m., with constant torque of 1,200 ft.-lb.

**Design.** Design of Electric Motors for Intermittent Service, C.Schiebeler. *Engineering*, v 132, Oct 30, '31, p 566-8. Study of conditions in motor when operating on short-interval intermittent service.

**Induction.** Induction Motors for Frequent Reversing, R.F.Emerson. *Power*, v 74, Nov 3, '31, p 637-8. Practical discussion of effects of motor-reversing operations; curves showing number of reversals possible with 50 deg. cent. rise when using general-purpose squirrel-cage motor and motor with high-resistance rotor.

**Railroad.** Field Shunting and Modern Motor Design, L.B.Hewitt. *Elec. Ry., Bus and Tram Jl.*, v 64, Mar 13, '31, p 141-3. If interest in this direction can be stimulated one may have hope that manufacturers will produce suitable motors designed for far greater range of field control than any at present on market; economies to be obtained together with savings in weight, cost of resistances, and control equipment would be more than adequate compensation.

**Single-Phase.** Capacitor Single-Phase Motors, L.T.Campey. *Maintenance Eng.*, v 89, Sept '31, p 427-31. Review of theory and design, and general statement of applications, discussing advantages and limitations; motor operation curves and control.

**Squirrel Cage.** Some Features of the Polyphase Squirrel-Cage Induction Motor, F.Miller. *Gen. Elec. Rev.*, v 34, Oct '31, p 548-52. Mechanical construction; stator windings; final drying and insulating; electrical relationships; characteristics of motor with respect to rotor design; characteristic curves as samples of rotor punching are given.

## NETWORKS

New System of Distribution. *Elec. News*, v 40, Nov 1, '31, p 35-7. Proposed type of general purpose system for moderately loaded areas that utilizes single conductor, shielded aerial cables, supported by messenger forming common neutral of 4,600/8,000Y volt circuit; details of system.

**Design.** A Proposed Type of General Purpose Distribution System for Moderately Loaded Areas, G.H.Underhill. *N.E.L.A.—Bul.*, v 18, Oct '31, p 669-77 and 693. Proposed system is advanced areas; it utilizing single conductor, shielded aerial cables, supported by messenger which forms common neutral of 4,600/8,000Y volt circuit. Paper won first award in James H. McGraw prize contest for 1931.

**Frequency Operation.** Changing a System Frequency—I, E.Smart. *Elec. Lt. and Pwr.*, v 9, Nov '31, p 26-8. Empire District Electric Co. of Joplin, Mo., completed 25-cycle to 60-cycle conversion project at cost of $2,000,000; project included replacement of original turbines and 25-cycle generators in Company's main hydroelectric plant on White River, with 60-cycle equipment having total capacity of 20,000 kw.; conversion of 66-kv. circuit and connections thereto to 60-cycle service.

## OSCILLOGRAPHS

**Cathode-Ray—Measurements.** Phase Measurements with the Cathode Ray Oscillograph, L.A.Wood. *Rev. Sci. Instruments*, v 2, Oct '31, p 644-8. Theoretical mathematical analysis, pertaining to suitability for oscillograph for this type of measurements.

## PHOTOELECTRIC CELLS

New Applications of Photo-Cells for Control of Handling Equipment, R.F.Yates. *Matls. Handling and Distribution*, v 6, Sept '31, p 45-6. Features of application of photo-cells for automatically controlling conveyoring equipment in filling of ore and grain bins.

Engineering Development of Photovoltaic Cells, C.G.Fink and D.K.Alpern. *Am. Electrochem. Soc.—Trans.*, v 58, '30, p 275-98. New photovoltaic cell, designed for industrial purposes, is described and some operating data and characteristic curves are presented, as introduction to general treatment of subject; cell contains lead anode and copper-oxide cathode.

**Applications.** Electronic Control of Machinery, R.F.Yates. *Iron Age*, v 128, Nov 5, '31, p 1170-2. Photoelectric tubes are designed for various specific operating conditions not admitting use of mechanical counters; thyratrons controlling comparatively large current without mechanical relays.

## POTENTIOMETER RECORDERS

New Brown Potentiometer Recorder, T.R. Harrison. *Rev. Sci. Instruments*, v 2, Oct '31, p 618-25. Brown potentiometer recorder is illustrated and described in some detail; is suited to use as self-balancing wheatstone bridge, for resistance thermometry, and for many other uses.

## POWER INDUSTRY

**Accounting.** Accounting Fundamentals Applied to Purchased and Generated Power, J.W. Romig. *Power*, v 74, Oct 27, '31, p 605-7. Separating fixed charges for economic comparisons; features of mixed-pressure unit; uses of variable and fixed costs.

**Rate Making.** How to Handle a Rate Case, C.B.Cooke,Jr. *N.E.L.A.—Bul.*, v 18, Oct '31, p 657-9. Cost-to-company is more practical and reliable index for permissible rates to large customers than value of service to them which is usually greater than can be obtained in rate.

## PUBLIC ADDRESS SYSTEMS

Design and Assembly of Outdoor Public-Address Systems, G.S.Mitchell. *Projection Eng.*, v 3, July '31, p 14-6. Instructive details of unit assembly and placement for outdoor sound transmission.

High Power for the Public-Address System, C.H.W.Nason. *Projection Eng.*, v 3, Oct '31, p 14. Availability of type 556 mercury-vapor rectifier simplifies construction of outdoor sound system; installation for theater, auditorium or outdoor use, wherever high quality channel of power involved is desired, is shown schematically.

An Audio-Radio Distribution and Control Circuit, R.P.Glover. *Electronics*, v 3, Oct '31, p 155. In some instances it would be desirable to retain feature of selection and control over radio programs at individual receiving points and at same time afford advantages of centralized distribution of voice and records; schematic diagram of such installation is shown.

## RADIO

**Antennas.** Development of Directive Transmitting Antennas by R.C.A. Communications, Inc., P.S.Carter, C.W.Hansell and N.E.Lindenblad. *I.R.E.—Proc.*, v 19, Oct '31, p 1773-1842. Various types of directive antennas are theoretically analyzed and their performances under practical conditions studied; effects of seasonal variations, heights above ground and polarization are considered; radiation properties of simple wires and radiation patterns of various combinations of wires are described in detail.

**Antennas—Short Wave.** Developments in Short-Wave Directive Antennas, E.Bruce. *Bell Syst. Tech. Jl.*, v 10, Oct '31, p 656-84. Previously indexed from *I.R.E.—Proc.*, Aug. 1931.

**Circuits.** Series Equivalent of a Resistance Paralleling a Tuned Circuit, C.H.W.Nason *Radio Eng.*, v 11, Oct '31, p 28. Simple mathematical analysis of determining effect of resistance and detector circuit.

**Engineers.** The Spokesman for the Radio Engineer, S.O.Hooper. *I.R.E.—Proc.*, v 19, Oct '31, p 1843-8. Radio today is compromise between engineers, department store managers, politicians, theater owners, and lawyers; had engineers proceeded properly in beginning they would have first reached accord among themselves as to what set-up should be; problem of getting Congress and executive branch to provide needed laws and regulations would have been very easy.

**Interference.** Radio Interference. *Elec. Mfg.*, v 8, July '31, p 31-2. Factors to consider when selecting motors; table shows part electric motors played in causing radio interference in 16 cities of less than 15,000 population.

**Interference.** High-Frequency Atmospheric Noise, R.K.Potter. *I.R.E.—Proc.*, v 19, Oct '31, p 1731-65. Method which has been employed in measurement of high frequency atmospheric noise is described; using this method measurements of noise over range from 5 to 20 megocycles made in different parts of U.S.A. and at different times of year, show distinct diurnal change in intensity similar to that for long-range high-frequency signal transmission.

**Inverters.** D-C. Inverter for Radio Receivers, W.R.G.Baker and J.I.Cornell. *Electronics*, v 3, Oct '31, p 152-4. Device for changing d-c. into a-c.; supplies a-c. from d-c. mains at required voltage and frequency and may be mounted in cabinet with receiver; development has been made possible through use of thyratron

**Receiving Apparatus, Short-Wave.** Factors in the Selection of the Proper Radio Power Transformer, J.A.Comstock. *Radio Eng.*, v 11, Oct '31, p 17-9. Transformer should meet tolerances set forth by radio engineer, and in most cases these are in neighborhood of plus and minus 3 per cent on filament windings and plus and minus 5 per cent on high voltage windings and be capable of withstanding dielectric tests specified by Underwriters' Laboratories, and application.

**Telegraph.** Application of Printing Telegraph to Long-Wave Radio Circuits, A.Bailey and T.A.McCann. *Bell Syst. Tech. Jl.*, v 10, Oct '31, p 601-15. Arrangements which have been used for start-stop printing telegraph operation over transatlantic long-wave radio channel.

**Waves, Long—Measurement.** Long-Wave Radio Receiving Measurements at the Bureau of Standards in 1930, L.W.Austin. *I.R.E.—Proc.*, v 19, Oct '31, p 1766-72. Tables of monthly average field intensities of various long-wave stations, and corresponding atmospheric disturbances measured in Washington in 1930.

**Waves, Ultra-Short.** The Attenuation of Ultra-Short Radio Waves Due to the Resistance of the Earth, R.L.Smith-Rose, and J.S.McPetrie *Phys. Soc.—Proc.*, v 43, Sept 1, '31, p 592-612. Investigation of attenuation of radio waves, of wavelengths between 5 and 10 meters, when transmitted directly along earth's surface; transmitters employed, one being fixed installation used with input power supply of order of 500 watts, other transportable set operated with input supply of about 50 watts obtained from batteries, are described.

## RAILROADS

**Controllers.** New Cam Type Controller. *AEG Progress*, v 7, Sept-Oct '31, p 190-3. Features and characteristics of new AEG type, *i. e.*, contacts, contact fingers, arc-extinguishing devices, contact pressure and action, contact battens, cam drum, notched wheel, reversing and braking drums; design of housing, connections and mode of operation; 60,000 km. service within interval of two main inspections without overhaul of contacts cited.

**Economics.** Economics of Electric Railway Operation, J.R.Ong. *Elec. Traction*, v 27, Oct '31, p 498-9, see also *Elec. Ry. Jl.*, Oct '31, p. 570-1. Faster schedules of paramount importance; new equipment increases riding; reducing operating expenses; savings in bus operation; savings in reducing costs of accident. Before A.E.R.A.

**Power Supply.** Power Generation and Distribution Have Undergone Many Changes, C.R. Harte. *Elec. Ry. Jl.*, v 75, Sept 15, '31, p 542-5. Historical review of power plant design and electric power distribution for street railroads; details of specific installations.

**Regenerative Control.** Tramway Regeneration, G.H.Fletcher. *Elec. Ry., Bus and Tram Jl.*, v 65, Sept 18, '31, p 132-45. Manchester Tramway System and Tramways Department of Glasgow decided made trial with Parisian system; in both cases series-parallel scheme was selected; results obtained from Manchester experiment; brief description of car and its equipment. Before Manchester Mun. Tramways and Transport Assn.

**Signals and Signaling.** Chicago, St. Paul, Minneapolis and Omaha Eliminates Nearly 20,000 Train Stops Annually. *Ry. Signaling*, v 24, Oct '31, p 337-41. Grade crossing with Chicago, St. Paul, Minneapolis and Omaha, gauntlet drawbridge, and junction switches controlled by table interlocking machine; mechanical gate protection solves light-traffic crossing problem.

**Signals and Signaling—Interlocking.** C.B. and Q. Installs Electric Interlocking, W.F. Zane. *Ry. Signaling*, v 24, Oct '31, p 331-4. Plant first of six large signaling units in rearrangements of Galesburg, Ill., terminal facilities; schematic diagram showing general layout; track-and-signal plan of controlled territory; outside equipment; cable distribution.

Power Interlocking Eliminates Delays. *Ry. Signaling*, v 24, Oct '31, p 342-4. Reconstruction program involves installation of two electro-pneumatic plants on Norfolk and Western at Portsmouth, Ohio; track layout; a-c. operation and control in both plants.

Chicago and Illinois Midland Installs Electric Interlocking. *Ry. Signaling*, v 24, Oct '31, p 335-6, and 341. Crossing with Wabash protected by modern plant; highway crossing protection special features; track-and-signal plan of plant at Springfield, Ill.; interlocking machine; signals and switch machines; special crossing signs.

Remote Control for Interlocking Saves $6000 Annually. *Ry. Signaling*, v 24, Oct '31, p 345-6. 30-lever plant, including highway-crossing protection now handled by all-relay control with 7-lever centralized-type machine in station 1.2 mi. away; control machine; layout plan of remotely controlled plant; control circuit; yard indicator.

**Signals and Signaling—Remote Control.** The Operation of Long-Distance Points by Hand-Generated Power—I. *Ry. Engr.*, v 52, Oct '31, p 370-4. Outline of systems whereby long-distance low voltage point mechanism operates without batteries; arrangement of lines and signals, circuits for long-distance point operation Great Southern Railways, Ireland; past and present arrangement of lines and signals at Collooney.

**Tracks.** Advances in Electric Railway Track Construction Standards. *Can. Ry. and Mar. World*, Oct '31, p 653-4. Diagrams illustrating design and constructional features.

**Train Control—Equipment.** How to Use a Train Control Output Meter. *Ry. Elec. Engr.*, v 22, Oct '31, p 268-9. Periodic checking of loop and track phase circuits provides means for determining condition of train control equipment and lessens possibility of failure.

## REACTORS

**Control.** Direct-Current Controlled Reactor, E.C.Wentz. *Elec. Jl.*, v 28, Oct '31, p 561-3. Long known as 3-legged reactor, apparatus is really analogous to 3-element amplifier tube and can be used as regenerative amplifier; it may also be used as relay, or as variable reactor; characteristic curves, practical uses and hook-ups.

## RECTIFIERS

Series-parallel Type Static Converters—II, C.A.Sabbah. *Gen. Elec. Rev.*, v 34, Oct '31, p 580-9. Polyphase series-parallel or series polycyclic static converter is discussed; definition and description; calculation of circuit; voltage relations; interphase transformer voltage; general graphical method and circle diagram or polar coordinates; numerical examples of calculation of 3-phase circuit by analytical method.

**Transformers.** Method for Eliminating Pulsations in the Terminal Voltage of Mercury Arc

Rectifiers, K.Ohsumi. *Inst. Elec. Engrs. Japan —Jl.*, v 51, July '31, p 380-5; see also English Abstract, on p 61-3. For extinguishing all alternating components from output voltage of rectifiers, author devised single-phase 3-winding transformer which is described in detail.

### REGULATORS

**Induction.** The Application of the Induction Voltage Regulator, W.E.M.Ayers. *Instn. Elec. Engrs.—Jl.*, v 69, Oct '31, p 1208-18 and (discussion) 1218. General application of induction regulators to feeder systems and distribution networks; problem of fully automatic control; application of regulator in system considered from its practical and economic aspects; financial aspect; twin polyphase induction regulators; special applications and connections.

### RELAYS

**Testing.** Theory and Application of Relay Systems—Relay Testing and Maintenance—I, R.H.Robinson and I.T.Monseth. *Elec. Jl.*, v 28, Oct '31, p 581-4. Investigation of new relays; initial tests; testing induction-type relays; directional tests.

### SUBSTATIONS

**Work Designs.** Tapping 110-Kv. Trunk Line to Serve Small Community. *Elec. World*, v 98, Oct 31, '31, p 776-7. Sevierville, 110/13.8-kv. substation of Tenn. Pub. Serv. Co., represents another effort on part of power companies to provide small community with good electrical service from high-voltage trunk line without unduly hazarding trunk-line service.

### SYMBOLS

**International Electrotechnical Commission.** International Symbols—III; Graphical Symbols for Weak-Current Systems. *I.E.C.—Pub.* no. 42, '31. Symbols for practical purposes representing object in very reduced and simple form and making it possible to draw any diagram in minimum time while giving it all desired clearness and convenient size. (In French and English.)

**Standardization.** The A.I. & S.E.E. Suggestions to the Electrical Manufacturers in Connection with Standardized Symbols for Control Apparatus. *Iron and Steel Engr.*, v 8, Oct '31, p 438-9 and (discussion) 439-45. Tab. of suggestions.

### TELEPHONE

**Exchanges—Airships.** Aerial P.B.X. on World's Largest Airship, A.Parlett, Jr. *Telephony*, v 101, Oct 31, '31, p 31-2. Description of telephone installation on U.S.S. Akron, world's largest airship recently built for U.S. Navy, comprised of specially constructed switchboard and 17 telephones.

**Receivers—Moving Coil.** Moving-Coil Telephone Receivers and Microphones, E.C. Wente and A.L.Thuras. *Bell Syst. Tech. Jl.*, v 10, Oct '31, p 565-76. Moving coil head receiver and microphone designed particularly for high quality transmission; instruments have substantially uniform response from 40-10,000 c.p.s.

**Relays.** Characteristics of Strowger Relays, K.W.Graybill. *Telephone Engr.*, v 35, Oct '31, p 30-1. Characteristics of various special types of relays in curves are given and explained.

**Systems—Interconnection.** Interconnection of Telephone Systems—Graded Multiples, R.I.Wilkinson. *Bell Syst. Tech. Jl.*, v 10, Oct '31, p 531-64. General problem of subscriber interconnection; economic and service factors in selection of trunking systems; characteristic manner in which telephone calls fall upon ordinary straight trunk groups; theoretical analysis of graded multiples from which are constructed curves for common probabilities of loss; comparison of theory and observation.

### TELEVISION

Technical Problems in Connection with Television, C.O.Browne. *Instn. Elec. Engrs.—Jl.*, v 69, Oct '31, p 1232-8. Present day television is confronted with two main problems, that of transmitting signals which correspond to picture elements necessarily embracing large frequency band; second, that of providing sufficient illumination on receiver screen to enable audience to view received image simultaneously.

**Apparatus.** A Television Projector for Screen Pictures. *Projection Eng.*, v 3, July '31, p 13. Projector type televisor, designed by DeForest engineers, which throws television pictures received on screen so that they may be seen by small theater audience; extreme flexibility for television flying spot, is obtained.

**Apparatus, Superheterodyne.** Television Reception with the Superheterodyne, R.W. Tanner. *Radio Eng.*, v 11, Oct '31, p 23-5. Engineering details of design of superheterodyne receiver suitable for television.

**Fidelity Charts.** Measurement of Fidelity in Television Systems, A.F.Murray. *Electronics*, v 3, Oct '31, p 137-8. Reproduction of charts devised in R.C.A. Victor Research Laboratory for measuring fidelity and for comparison of shades.

### THERMOCOUPLES

New Uses for the Thermocouple. *Projection Eng.*, v 3, Oct '31, p 13 and 15. New type of thermocouple potentiometer of General Electric Co. for accurate temperature measurements; principle overcomes need for standard cell, which requires frequent balancing to make certain that potentiometer current has not varied.

### TRANSFORMERS

Recent Progress in Large Transformers, R.M. Charley. *Instn. Elec. Engrs.—Jl.*, v 69, Oct '31, p 1189-1207. General description of progress made in recent years and examples illustrating present stage of art; notes on problem of transport; comparison of 3-phase units with banks of single-phase units; shell-type vs. core-type transformers; core construction; cooling; "Intertaire" transformers; Buchholz protective device; interturn insulation; non-resonanting transformers, etc.

**Connection.** Calculation of Line-to-Line Ratios and Phase Angles of a Combination of Three Single-Phase Voltage Transformers Star-Connected on a Three-Phase System, The Star Point being Earthed, A.O.Crawley. *Instn. Elec. Engrs.—Jl.*, v 69, Oct '31, p 1293-4. Development of algebraic expressions for calculation of ratio and phase-angle errors from measured values.

**Silica Gel Breathers.** A Silica Gel Transformer Breather. *Engineer*, v 152, Oct 16, '31, p 418-9. Particulars of breather for transformers, designed to replace those employing calcium chloride; breather can be made for all capacities and can also be applied to joint boxes and oil transport and storage tanks.

### TRANSMISSION LINES

**Calculation.** Symmetrical Components—IX, C.F.Wagner and R.D.Evans. *Elec. Jl.*, v 28, Oct '31, p 586-90. Discussion of phase sequence constants of transmission lines with ground wires; positive and negative sequence impedance; zero-sequence impedance; practical calculation of zero-sequence impedance; electrical characteristics of steel ground wires; copper-clad steel cables.

**Failures.** Interruptions to Lines Concentrated at Sunrise—Why? E.E.George and W.R. Brownlie. *Elec. World*, v 98, Oct 10, '31, p 658-61. Idea of relative importance of lightning and other causes may be had from record of 110 kv. and 154 kv. outages on Tenn. Elec. Pwr. Co.'s transmission system; 70 per cent of non-lightning outages fall in sunrise band; switching operations shifted away from sunrise period.

**Rural—Costs.** Rural Lines for $500 per Mile, M.T.Crawford. *Elec. World*, v 98, Oct 17, '31, p 690-1. Northwest Elec. Lt. and Pwr. Assn., surveyed practise of all member companies and prepared data on types of construction indicating present general practise; cost of special type of construction of Portland Gen. Elec. Co., adding 15 per cent overhead and reasonable amount of secondary circuit, transformers and meters will not much exceed $500 per mile.

### VACUUM TUBES

**Industrial Application.** Electron tube in Machine Design, R.F.Yates. *Machy.* (*N.Y.*), v 38, Oct '31, p 95-6. How vacuum tube, photoelectric cell, and grid-glow tube are being used by machine designers for grading, measuring and counting.

### WATER HEATING

New Possibilities in Off-Peak Water Heating, *Elec. West*, v 67, Oct 1, '31, p 179-81. After study of some months' duration involving analysis of experience with high-voltage water heaters on meter rate and low-wattage heaters on flat rate, and experiments with various types of heaters, tanks and insulation, Puget Sound Pr. & Lt. Co., Seattle, has established new water heating rate offering low priced energy on off-peak hours for storage-type water heaters.

### WELDING

**Arc.** Developments in Arc Welding as Applied to Oil Industry, J.C.Lincoln. *Oil Weekly*, v 63, Oct 16, '31, p 18-24. Application of shielded arc process to welding of pipe lines, oil tanks, vaporizer tubes and other fields and refinery equipment. Before Am. Petr. Inst.

Shielded Arc and the New Code, G.Raymond. *Welding Engr.*, v 16, Sept '31, p 42-4. Qualities of weld metal which are called for by revised A.S.M.E. boiler code; corrosion resistance of shielded arc weld demonstrated by deep etching test; tensile tests of shielded arc welds through which holes have been drilled; bend tests demonstrate ductility and toughness.

**Bronze.** Improved Product by the Use of Bronze Welding, H.F.Reinhard. *Am. Welding Soc.—Jl.*, v 10, Oct '31, p 5-8. Bronze welding as applied to light gage galvanized sheet steel and iron in fabrication of house lighting and cooking type acetylene generator; bronze welded seams 315 per cent stronger than soldered double-lock seams.

**Locomotive Boilers.** Welding Practise in Northern Pacific Boiler Shops. *Boiler Maker*, v 31, Oct '31, p 274-7. Details of welding equipment and practise.

**Locomotive Fireboxes.** Welding in the Locomotive Boiler, J.M.Vossler. *Welding*, v 2, Oct '31, p 679-81. Practise of Southern Pacific Lines, Houston, Tex.; joining sheets in locomotive firebox by electric arc process. (To be concluded.)

**Machines, Spot.** Heavy-Duty Spot-Welding Machine. *Engineering*, v 132, Oct 23, '31, p 539. Machine by British Insulated Cables, Ltd., is suitable for making welds up to ½ in. in diam. in two or more pieces of mild steel having total thickness up to ¾ in., and at speeds up to 600 welds per hr.; comprises 60-kw. single-phase, air-cooled transformer.

**Machinery Bases.** Reducing Weight and Production Costs, C.M.Taylor. *Welding Engr.*, v 16, Sept '31, p 58-60. How bending brake and electric arc work together to improve design of machine bases and cut cost of manufacture.

**Machine Tool Manufacture.** Machine Tool Frames Produced by Welding, J.R. Weaver. *Machy.* (*N.Y.*), v 38, Nov '31, p 171-3. Principles governing construction of machine tool frames and bases by arc welding illustrated by examples.

**Pipe.** Welding of Copper and Brass Pipe, H.V.Inskeep. *Am. Welding Soc.—Jl.*, v 10, Oct '31, p 21-4. Research work at Union Carbide and Carbon Research Laboratories to determine best types of joint.

**Pipe Joints.** Four Problems Encountered in Flash Welding Mild Steel, E.R.Torgler. *Am. Welding Soc.—Jl.*, v 10, Sept '31, p 29-33. Welding methods in manufacture of Dresser type couplings of 8 to 26-in. diam. with particular regard to flash welding of mild steel middle ring; determination of necessary flash and upset (burn and jam) for satisfactory middle ring flash weld; photomicrograph illustrates structure; secondary piping and segregated impurities as causes of defective flash welds; comparison between flash weld and roll weld.

**Pipe Lines.** Welded Pipe and Fittings in Heating Installations, F.J.Maeurer. *Am. Welding Soc.—Jl.*, v 10, Sept '31, p 5-13. Efficiency; economy; weight saving; fabrication of joints; fabrication of headers; welding fittings; spacing and tacking; expansion and contraction; adaptability and portability of oxyacetylene apparatus; welding piping in home; reduction of friction loss in welded fittings.

**Rails.** The Electric Welding of Battered Rail Ends. *Engineering*, v 132, Oct 2, '31, p 452. Canadian Pacific Railway authorities have been experimenting, during past 3 years, in hope of developing economical means of building up battered rail ends by electric welding.

Committee on Welded Rail Joints—Progress Report No. 7. New York, American Bureau Welding, A.E.R.E.A. and U.S. Bureau Standards. May '31, 62 p. Outline of following Bureau of Standards progress reports: Preheating and Postheating; Hardness Tests Along Thermit Welded Unit; Hardness Tests Along Thermit Welded Rail Joint; Metallographic Examination of Thermit Welded Rail Joint; Results of Shearing Tests of Small Preheated and Postheated Welded Specimens of Investigation No. 3 Revised; Repeated Impact Tests of Rail Joints of Investigation No. 2.

**Structural Steel.** Jig Assembly for Welding Fabrication Proves Its Efficiency. *Eng. News-Rec.*, v 107, Oct 29, '31, p 688-9. Fabrication of steel for new all-welded shop building at Barberton, Ohio, plant of Babcock & Wilcox Co.; results showed 10 per cent saving over estimate for riveted building.

Report of Structural Steel Welding Committee. *Am. Welding Soc.—Jl.*, v 10, Oct '31, p 25-42. Investigation extending over period of 5 years; determination of stresses that may be safely used in designing of welded steel structures fabricated under ordinary commercial fabricating shop conditions. (To be continued.)

### WELDS

**Testing.** Stethoscopic Examination of Welded Products, J.R.Dawson. *Power Plant Eng.*, v 35, Oct 15, '31, p 1016-17. Hammer tests can be effectively used on welds; testing equipment and procedure. Before Am. Welding Soc and A.S.T.M.

**X-Ray Analysis.** X-Ray Examination of Welded Pressure Vessel Seams, A.J.Moses. *Combustion*, v 3, Sept '31, p 17-20 and 35. With recent formulation of A.S.M.E. code for welded boiler drums, technique and methods of testing used in manufacture of welded drums have taken on added interest and importance; outline of X-ray method of testing; features of installation of X-ray equipment which is representative of latest development in this field.

### WHEATSTONE BRIDGE

A Voltage Selective Nonlinear Bridge, C.G. Suits. *Physics*, v 1, Sept '31, p 171-81. Important property of simple series resonance circuit employing resistance, capacitance and iron core reactor arranged to saturate is abrupt increase in current at certain critical voltage; this phenomenon is identified as quasi-resonant condition, and is compared to resonance in linear circuits; experimental study is made of nonlinear bridge circuit comprising two branches of above type.

**Capacity.** Two Precision Condenser Bridges, A.Campbell. *Phys. Soc.—Proc.*, v 43, Sept 1, '31, p 564-8. To facilitate direct reading of both capacitance and power-factor, the author has developed two bridge systems, based on that of Carey Foster.

# Industrial Notes

**Westinghouse and Italian Company to Exchange Patents.**—According to F.A. Merrick, president of the Westinghouse Electric & Manufacturing Company, an agreement has been concluded with Ercole Marelli & Company of Milan, a leading Italian electrical manufacturing concern, for an exchange of patents and experience. The Westinghouse companies will not participate financially nor take any part in the management of the Italian company.

**Square D Promotions.**—G. Lewis Hull, sales manager, switch and panel division of the Square D Company, announces the appointment of C. W. Bates, formerly Chicago branch manager, as assistant sales manager. G. S. Blomgren, of the Chicago office, succeeds Mr. Bates as Chicago branch manager. Mr. Bates' headquarters will be at the Detroit factory of the Square D Company.

**The Corning Glass Works, Corning, N. Y.,** has appointed the Bra Bon Electric Company, Inc., with offices in the Lewis Tower Building, Philadelphia, as agents for the sale of PYREX power insulators. The territory covered will include parts of New Jersey, Pennsylvania, Maryland, District of Columbia and the states of Delaware and Virginia.

**Herbert S. Glasby,** who has been associated with the Acme Wire Company, of New Haven, Conn., has opened a sales office at 123 South Broad Street, Philadelphia. In addition to handling the line of magnet wire, coils, varnished insulations and condensers made by the Acme Wire Company, he will represent the National Harris Wire Company, of Newark, N. J., manufacturers of high resistance alloy wires and ribbons; the MacAllen Company, of Boston, producers of mica sheet, tapes and molded articles, and the Waterbury Button Company, Waterbury, Conn., makers of bakelite, durez and other high dielectric molded products.

**A New Time Switch.**—The Sangamo Electric Company, Springfield, Ill., has announced for January deliveries a very moderately priced, electrically wound time switch. The main spring, kept wound by a constant speed a-c. motor, has ten hour reserve power to carry through any ordinary current interruption. A jeweled balance with non-magnetic, non-rusting, temperature compensating, special alloy hairspring, guarantees dependable timing. One of the unique features of this new switch is the type of mechanical contact which is being introduced in this country, after being used successfully abroad for many years. This new contact has a slow opening and a small gap. It is revolutionary, but has been thoroughly tested and is guaranteed by the makers. The standard switch has levers for three complete daily operations, allowing for either one, two, or three, on and off periods each day. Manual operation does not affect the sequence of subsequent operations. A Sunday and holiday cutout is also supplied. The entire timing and winding mechanism is enclosed in a dust-proof case. This unit, complete with contact mechanism and molded bakelite connection block, is mounted in a pressed steel case.

**An Improved Lamp Cord.**—The Simplex Wire & Cable Company, Boston, has introduced "Latox" rubber sheathed twin lamp cord, a new type of flexible, rubber insulated cord suitable for portable lamps, fans, clocks, toys and similar apparatus. It is a small, durable cord with a thin covering or sheath of tough, new type, rubber compound in place of the usual silk, rayon or cotton braids. The rubber sheath is furnished in black, green, or brown-mahogany and retains a satin-smooth, highly polished finish indefinitely. The advantages claimed for the new cord are that it will never fray, it does not gather dust or lint, is sanitary, will not absorb moisture, and wiping with a damp cloth restores its freshness when soiled.

# Trade Literature

**Instrument Transformers.**—Catalog GEA-601C, 42 pp. Describes General Electric standard lines of switchboard, portable and laboratory instruments. Dimensions and typical scales of certain lines are included. General Electric Company, Schenectady, N. Y.

**Illuminating Equipment.**—Bulletin, Serial No. 754, 28 pp., "Planned Lighting," described as a comprehensive manual for planning almost every form of illumination. Illustrated and includes detailed sketches and data on wattage capacities. Curtis Lighting, Inc., 1123 W. Jackson Blvd., Chicago.

**Motors.**—Bulletin 167, "Small Motors," 30 pp. The bulletin, in loose-leaf form, is divided into eight parts describing single-phase, polyphase and direct-current motors in fractional horsepower ratings. At present only five of the eight parts are available, but the missing three parts will be mailed at a later date to all who request a copy of No. 167 at this time. Wagner Electric Corporation, 6400 Plymouth Avenue, St. Louis.

**Illuminometer.**—Bulletin 4 pp. Describes a new instrument which reads illumination intensities with the same ease and facility as reading ammeters and voltmeters. Known as the Model 603 Illuminometer, it consists of an indicating instrument and a light target assembled in a portable case. The light target is on the end of a flexible cord so that it may be placed in any position. This light target, or searching unit has two photronic cell units which convert light energy directly into electrical energy without the use of batteries or other auxiliary voltage. They maintain constant output over long periods of time and there is no dark current. The output from the photronic cell units is considerable, allowing the use of a rugged portable instrument calibrated directly in foot-candles. There are three ranges on the instrument, namely, 10, 50 and 250 foot-candles. A range changing switch is provided for the selection of the desired scale. Other combinations of ranges are being added to the line and will be available shortly. The light target may be placed at a distance from the observer so that shadows and lights reflecting from light clothing will not cause errors in readings. Light may be read from all angles and the light target may be placed in relatively inaccessible places, in show cases, windows, etc. The absorption of light by painted walls, screens draperies, etc., can be measured directly by turning the light target so that it faces the surface. The time required to make a lighting survey is about one-tenth of that previously required. Weston Electrical Instrument Corp., 584 Frelinghuysen Ave., Newark, N. J.

**Bus Connectors.**—Catalog 31, 96 pp. Describes "Memco" bus connectors and ground fittings. In addition to conventional designs of clamped and soldered bus connectors, two original and unique designs in clamped connectors are presented. One is the "Pliaband" design, which is a bolted connector, so designed as to adapt itself to the minor irregularities and variations in the circumference of the bus. It is primarily a high capacity fitting for important connections. The "Wedge-Grip" connectors are, as the name implies, based on the use of high pressure contact as secured from the wedge principle. Each connector of this type accommodates from eight to twelve sizes of wire and cable. In addition, a complete line of fittings are listed for modern "flat type" substations. The engineering section of the catalog contains a number of original tables and charts which will be found very helpful as short cuts in substation design work. It also includes the principal NEMA standards as relating to outdoor substation practise. Memco Engineering & Manufacturing Co., Inc., 37 Ninth Street, Long Island City, N. Y.

# Present Practise in Insulated Power Cables

Essential characteristics and latest developments in power cables are reviewed briefly in this article. Consideration is given to the three principal insulation materials, to different types of cable, and to impregnating compounds. In addition to summarizing present power cable practise in this country, future trends are indicated.

By
DONALD M. SIMMONS
Fellow A.I.E.E.
General Cable Corp.,
New York, N. Y.

IN CONSIDERING power cables we naturally think of three types of insulation: rubber, varnished cambric, and paper. There are quite definite limits for each type, governed principally by their electrical and physical characteristics as influenced by economics. The comparative merits of the three types of insulation will be considered first, and then each will be discussed separately. The general characteristics of the three types are presented in Table I in an illustrative manner.

The standard specifications which previously have been generally accepted for rubber compound used on insulated wire prevent manufacturers from using certain well-known and desirable ingredients. These specifications in the past have demanded a chemical test to prove that the compound contains a stated percentage of rubber. Materials which have been largely responsible for the advance of the rubber industry in other lines and for the saving of millions of dollars yearly have been prohibited for use in cables, merely because certain very advantageous ingredients interfere with the chemical tests for percentage of rubber. In recent years it has been realized more and more clearly that great advances could be made if rubber insulation could be judged not by chemical analysis of ingredients but by tests which show its performance and give an indication of its length of life.

While probably no tests will prove definitely that a certain compound will have a life of ten years or thirty years, tests have been developed which so closely simulate service conditions that they are entirely adequate to prove that one insulation will have a much longer life than another. These tests, are: first, the Geer test in which test samples are suspended in an oven at 158 deg. fahr. and hot fresh air is allowed to circulate; and second, the oxygen-bomb test, usually considered superior to the Geer test, and based on the fact that deterioration in rubber compound usually is due to oxidation. The samples are placed in a bomb filled with oxygen under 300-lb. pressure at 158 deg. fahr. In both the Geer and bomb tests, samples are taken out and are tested for tensile strength and elongation, the resulting values being plotted against time. A third and valuable form of test is the ozone test, in which rubber-insulated conductors in various forms are placed near a grounded metal plate and a sufficiently high voltage applied to cause the breakdown of the air external to the rubber, thus exposing the insulation to the action of ozone.

Table I—Characteristics of Cable Insulation

| | Rubber | Varnished cambric | Paper |
|---|---|---|---|
| Moisture resistance | Very High | Fair | Hygroscopic |
| Max. allowable temperature | 60 deg. cent. | 75 deg. cent. | 85 deg. cent. |
| Can be bent to | 6 diam. | 8 diam. | 12 diam. |
| Affected by corona or ionization | Yes | Resists | Resists |
| Life | Fair | Long | Long |
| Power factor 60 deg. cent. | 5% | 6% | 1% |
| Installation and jointing | Very easy | Easy | Requires care |
| Can be used non-leaded | Yes | Yes (indoors) | No |
| Dielectric strength in volts/mil for 1 hr | 250 | 250 | 400 |
| Standard test voltages in volts/mil | 70 | 125 | 200 |
| Specific inductive capacity | 3.5 to 6 | 3.5 to 6 | 3 to 4 |

Typical curves obtained by the oxygen bomb test are shown in Fig. 1. It will be seen that the standard specification of the A.R.A gives a compound which deteriorates rapidly, while a performance compound containing 30 per cent rubber judged by the performance standard rather than by chemical tests is affected very little, and a special heat-resisting stock is hardly changed at all. The N.E.L.A. and the A.S.T.M. lately have adopted tentative standards for judging rubber compounds by performance tests rather than by purely chemical tests. These undoubtedly will make future progress more rapid and will result in a large economic saving to the electrical industry.

---

**Table II—Insulation Recommended for Station Cables**

| Nominal system voltage | | Preferred insulation for non-leaded cables | |
|---|---|---|---|
| From | To | First | Second |
| 0.... | 600 .. | Rubber........... | |
| 601.... | 4,000 .. | Rubber........... | Varnished cambric |
| 4,001.... | 13,200 .. | Varnished cambric. | Rubber |
| 13,201.... | 17,000*.. | Varnished cambric. | Paper (lead-covered) |

*At voltages higher than 17,000 volts, paper-insulated lead-covered cables should be used.

Varnished cambric has a higher dielectric loss than now obtainable with paper, and due to the method of manufacture, contains some air and moisture. The present trend is toward a reduction in the dielectric loss as well as a different application of the tapes so that wrinkles and voids will be largely eliminated. Many years ago it was found necessary in the manufacture of paper cable to apply the paper tapes so that they butted instead of overlapped. Only recently this has been used on varnished cambric. These two types of tape application are shown in Fig. 2, except for the cases of small sizes of conductor and thin walls, the freedom from wrinkles in the butted construction increases the dielectric strength, greatly improves the ionization characteristics, and is undoubtedly an important step in the direction of improvement of varnished cambric cables.

Varnished cambric when leaded is more costly than paper and rarely is used for underground transmission. For station work, however, it is sufficiently resistant to moisture to operate without a lead sheath and terminals, and thus varnished cambric braided cable often has considerable advantage in cost over other forms. Table II shows recommended types of insulation for station cables.

Impregnated-paper insulated cable is used universally for underground transmission of large blocks of power and for high voltage work. It is not only the least expensive type of cable available for this purpose, but also it has by far the highest dielectric strength, longest life, and greatest reliability. For voltages of 33 kv. and over, it is at present the only type which can be used successfully and economically.

Up to a few years ago, multi-conductor cables were mostly of the belted type, a cross-section of which is shown on the left in Fig. 3. These cables proved fairly satisfactory for voltages up to 26 kv.; however, when it was attempted to use this construction at 33 kv., the belted cable was found entirely inadequate unless very heavy walls of insulation were used. It was proved that the weakness was not the insulation proper but the filler spaces. The filler material is inherently weaker than the conductor insulation, and furthermore, the stresses in the outer layers of conductor insulation have a component of force parallel to the layers, by far the weakest direction. Another weakness was that during motion of the cables, separation took place between insulated conductors, creating voids in the filler spaces. All these effects resulted in charring and burning of the filler spaces and outer layers of conductor insulation, often resulting in failure of the cable.

The solution to all these difficulties is the type *H* cable, so named from its inventor, Martin Hochstadter. The three-conductor type *H* cable is shown in the middle in Fig. 3. This design with a metal foil enclosing the conductor insulation prevents all the troubles of the belted cable because the filler spaces are completely shielded from electrical stress. Furthermore, the type

*H* cable has a considerable advantage in current-carrying capacity. In the first place, being electrically equivalent to three single-conductor cables under a lead sheath, it can be operated at the higher temperatures permissible for single-conductor cables. Secondly, copper has about three thousand times the thermal conductivity of paper. Copper foil therefore is very effective in conducting heat out to the lead, resulting in a reduced temperature rise of the copper above lead. The gain due to higher permissible temperature is independent of installation conditions and increases with working voltage. The increased current-carrying capacity for underground and aerial cables is shown graphically in Fig. 4.

The remarkable performance of type *H* cable has led to its practically complete adoption for voltages 20 kv. and higher in this country and abroad; in fact, it is in very general use down to and including generator voltages on the order of 11 kv. Due to the elimination of filler stresses, it is now possible to make multi-conductor cables for any voltage except where questions of diameter impose a limitation.

Type *H* construction is used also on single-conductor high-voltage cables, metallized paper being applied to the surface of the insulation as shown on the right in Fig. 3. The function of the metallized paper is to shield from all electrical stress, any voids which may occur between insulation and lead, such voids being formed when the cable is bent or when the lead sheath is stretched by the expansion of the compound under load cycles.

## A-C. RESISTANCE OF THREE-CONDUCTOR CABLE

Due to the recent use of larger and larger sizes of conductor in three-conductor cables up to 750,000 cir. mils for instance or even 1,000,000 cir. mils, it has become increasingly important to know accurately the effective a-c. resistance and reactance of such cables. These cables have additional losses due to skin effect, proximity effect, losses in the metallic binder tape, and in the lead sheath. The problem of these extra losses is important from the loss standpoint and from the standpoint of paralleling cables; it is being studied cooperatively by the Insulated Power Cable Engineers Association, some utilities, and the Electrical Testing Laboratories.

Some theoretical calculations made of losses, and which are quite close to actual measured values are shown in Fig. 5. It will be noted that the increase of a-c. effective resistance is considerable for the larger sizes. At first it was thought that the extra losses were in the magnetic steel binder tape used in type *H* cable. While final results have not yet been obtained and while

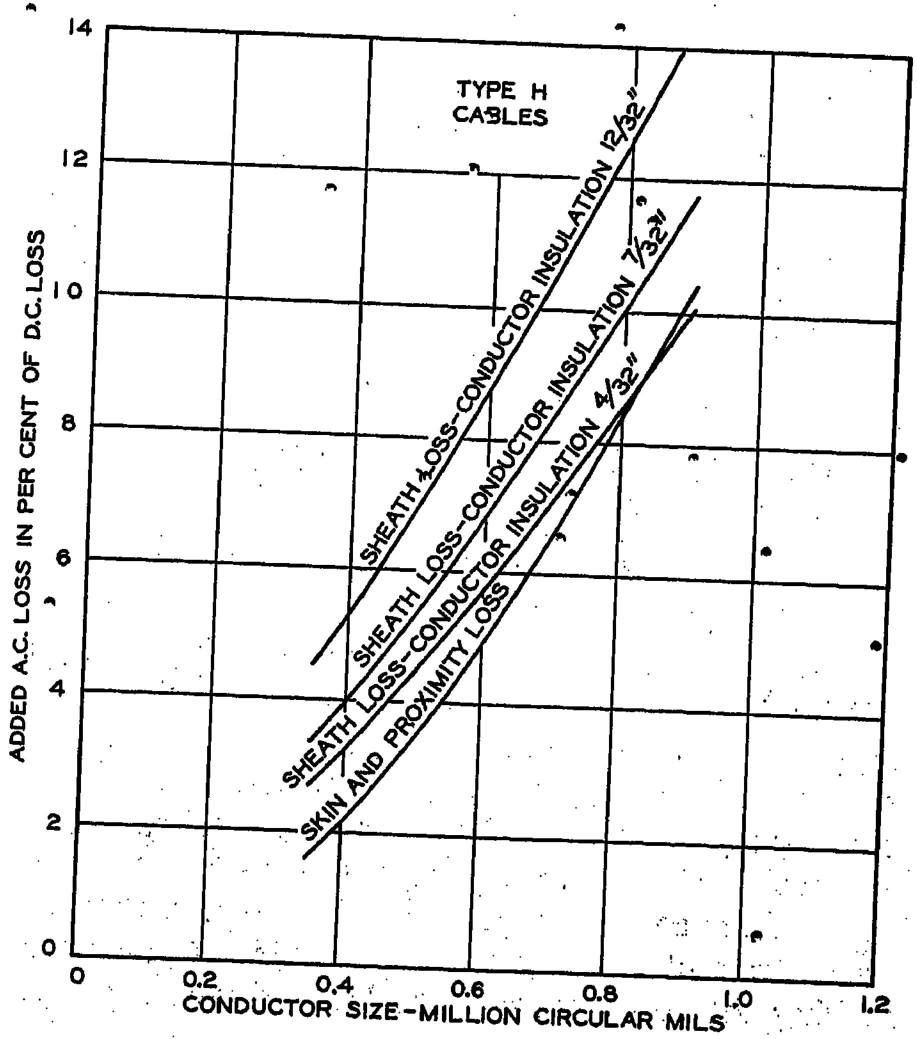

**Fig. 5. Added a-c. loss in three-conductor cables at 60 cycles and 20 deg. cent. Sector cable with 9/64-in. lead and non-magnetic binder tape**

Added a-c. loss = skin and proximity loss + sheath loss

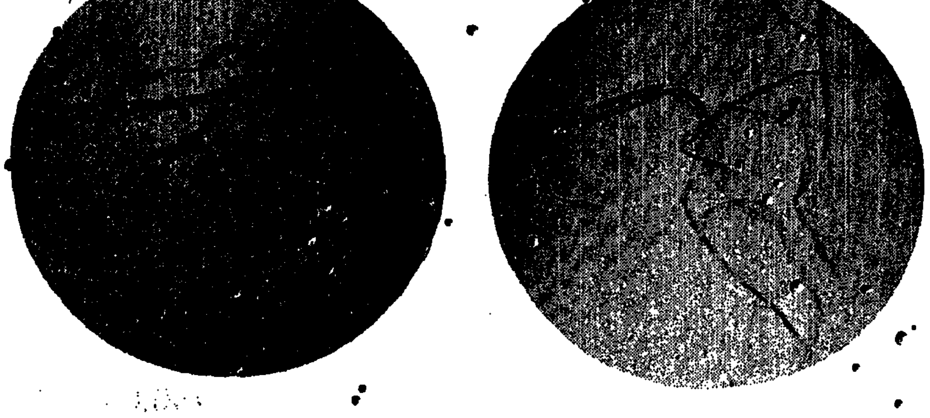

Fig. 6. Photomicrographs of fibers from ordinary wood pulp paper (left) and super-calendered wood pulp paper (right)

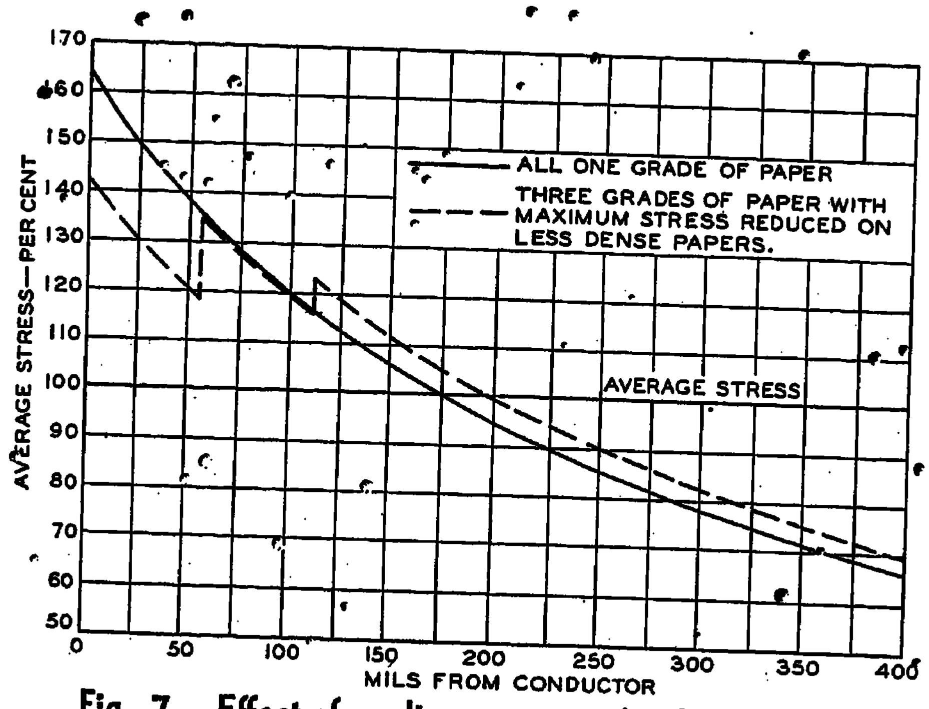

Fig. 7. Effect of grading on stress distribution with 4/0 round conductor and 406-mil paper

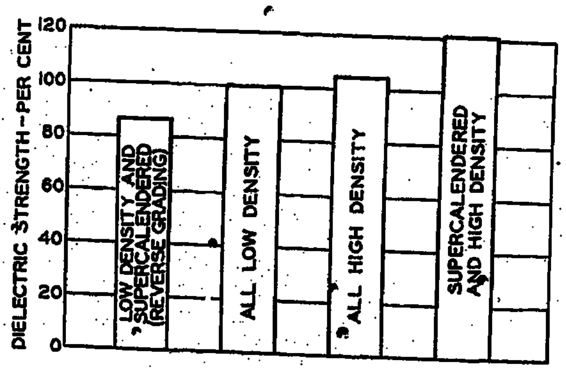

Fig. 8. Effect of grading on dielectric strength

there are differences from cable to cable, apparently at full load current there is very little difference in loss between a belted cable, a type *H* cable with a steel-binding tape, or a type *H* cable with a non-magnetic binding tape. Further, it appears that while there is a loss in the steel binder tape, its presence shields the lead sheath from some induction and thus reduces the losses by an amount about equal to the loss in the tape, thus making the total loss more or less independent of the type of construction.

Possibly the most important result of the study has been the emphasis that there is a considerable increase of reactance due to magnetic binder tape. The reactance of cables is so low that the increase is not of great importance in itself, but it is very important when studying the question of parallel operation of cables. The increased reactance ranges from an increase of 25 per cent in a three-conductor 350,000 cir. mil cable down to about 15 per cent for a three-conductor 1,000,000 cir. mil cable.

## MATERIALS

For many years most cable specifications required the use of manila rope paper, *i. e.*, paper made from fibers obtained from used manila rope. In recent years, however, wood pulp paper made by the sulphate process has been almost universally used in paper cable. It is usually made from Swedish pulp. This resulted in a great economy, and is responsible partially for the great increase in dielectric strength that has been evident in paper cables.

As the name implies super-calendered paper is paper which has been subjected to an additional calendering process which results in very dense paper having about 15 per cent higher dielectric strength and 30 per cent higher mechanical strength. Photomicrographs of ordinary and super-calendered fibers are shown in Fig. 6. The central channels apparent in the fibers of ordinary paper are not present in the super-calendered fibers, which are ribbon-like. The result is that for super-calendered paper there is no necessity for the difficult operation of eliminating the air and moisture in the channels of the fibers. Furthermore as can be seen from the pictures, the fibers are very much more closely packed together, with more fibers per unit volume, resulting in a greatly increased barrier action against all ions present, thus producing higher dielectric strength. Super-calendered paper also has a higher specific inductive capacity and with its higher dielectric strength, it is the ideal material to place next to the conductor where the stress is highest; it thus becomes possible to grade the insulation so that the maximum stress near the conductor is materially reduced. The improved stress distribution that may be secured is illustrated in Fig. 7.

The effect of using graded insulation, by which is meant the use of papers having different specific inductive capacities, is shown in Fig. 8. It will be seen that with super-calendered paper and high density paper there is an increase of 22 per cent over-all dielectric strength. The left-hand figure is of interest, showing that with reverse grading, *i. e.*, with super-calendered paper on the outside, the dielectric strength was reduced actually, as it is theoretically.

The breakdown strength of impregnated paper with its alternate layers separated by thin films of oil or compound is very much higher than the strength of either paper or compound alone; in fact, the electrical strength of impregnated paper is very much higher than that of any other materials available as cable insulation. In the early days, very viscous compounds composed of mixtures of rosin and rosin oil ordinarily were used.

These early materials, however, had high dielectric losses, and the next step was the use of mineral materials such as petrolatum, mixed with rosin. The insistent demand for still lower losses soon led to compounds of the nature of petrolatum thinned with transformer oil. Such compounds have low losses but some of them were not sufficiently stable chemically under the severe requirements of service. Mineral oils of the cylinder oil type which can be mixed with rosin or rosin oil and which have losses even lower than those obtained with the 100 per cent mineral compounds now are available.

There always has been more or less diversity of opinion as to relative merit of straight mineral oil or a mixture of mineral with rosin or rosin oil. The laboratories of the company with which the writer is associated have proved that high-grade rosin or rosin oil acts as an anti-oxidant when added to mineral oil in the proper proportion, mixed, and aged at the proper temperature. Rosin increases the stability of the resultant compound when subjected to dielectric stresses and its resistance to the so-called "wax formation" is greatly increased. It is of course necessary to select the proper grade of mineral as well as rosin oil so that the latter will remain in solution in the former. The photomicrographs in Fig. 9 show the appearance of proper and improper mixtures; the large undissolved crystals of rosin in the photomicrograph on the right are to be noted.

The effect of differences in impregnating compounds on the voltage-time characteristics of cable are shown in Fig. 10. Curve $X$ is for a compound containing no rosin or rosin oil; it was used several years ago but with great success. Curve $Y$ is made on cable insulated with a special mineral-oil rosin-oil compound. Note the slope of the curves as well as the fact that after two hours application of voltage they have about the same breakdown strength, whereas for long-time tests, there is a great gain for the one compound. Other things being equal, the superiority of compound $Y$ is quite obvious.

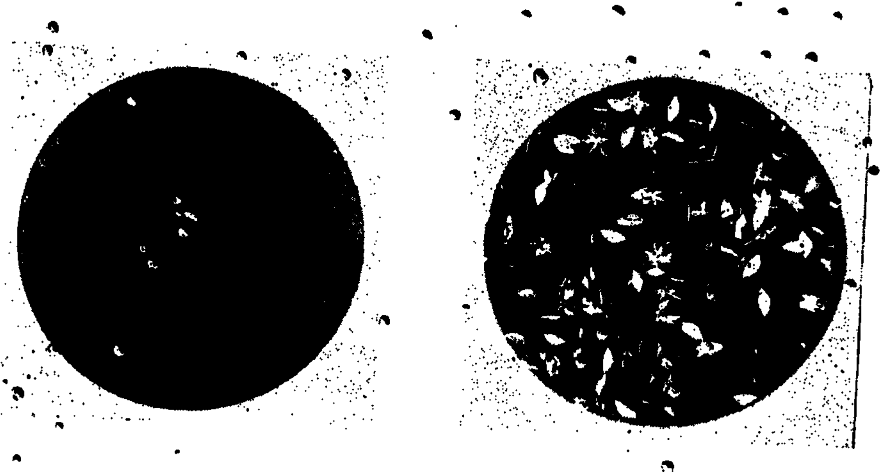

Fig. 9. Photomicrographs of different mixtures of impregnating compound

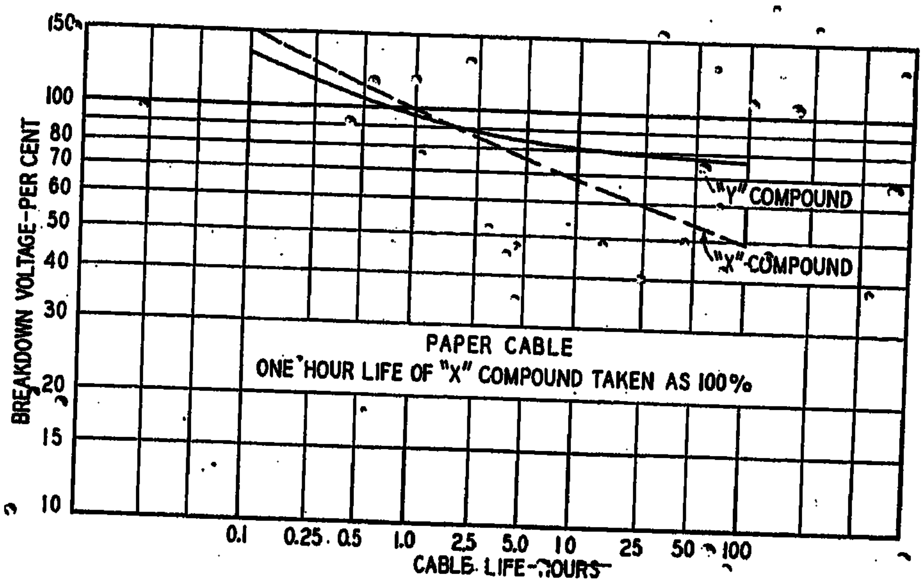

Fig. 10. Effect of different impregnating compounds on cable voltage-time characteristics

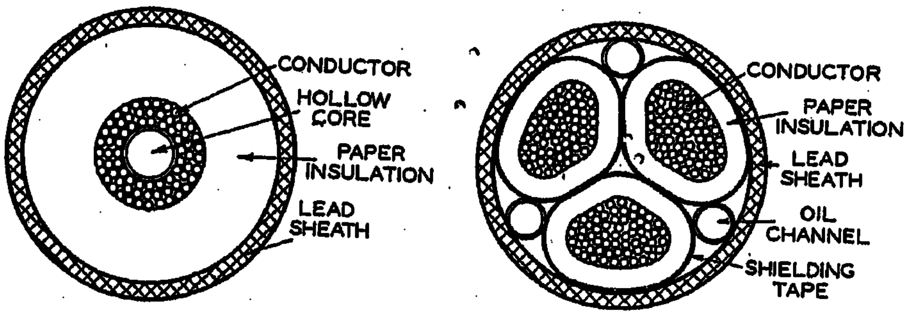

Fig. 11. Cross-section of single-conductor 132-kv. oil filled cable (left) and of three conductor 33-kv. type H oil-filled cable (right)

## OIL FILLED CABLE

The greatest and most spectacular development of cables for many years has been the advent of the oil filled cable. An ordinary cable is impregnated with what might be called an oil, but it is a fairly viscous oil which is not fluid at all operating temperatures, nor is the cable constructed to permit oil flow. Consequently, due to the large coefficient of expansion of the oil when the cable is heated, the compound will expand radially and stretch the lead. When the compound contracts, the lead will not contract and partial vacuums or voids are created in the insulation. This phenomenon is the main enemy of cable insulation.

In an oil filled cable, a thinner oil is used which is fluid at all operating temperatures; channels are provided for oil flow. When the cable is heated by load and the oil expands, the oil can flow lengthwise of the cable through the channel or channels of the cable into the joints and out into reservoirs. When the cable cools and the oil contracts, it is forced back into the cable by pressure on the reservoirs, and no voids are created. Cross-sections are shown in Fig. 11 of a single-conductor 132-kv. oil filled cable and a three-conductor 33-kv. oil filled cable. The subject of modern oil filled cable practise was covered in three papers recently presented before the Institute. Articles based upon these were published in ELECTRICAL ENGINEERING for November 1931, as follows: "Economics of High Voltage Cable," by D. W. Roper, p. 874-8; "Layout of Oil Filled Cable Systems" by G. B. Shanklin and F. H. Buller, p. 878-80; and "Accessories for Oil Filled Cable" by R. W. Atkinson and D. M. Simmons, p. 880-2.

The practical operating results obtained with oil

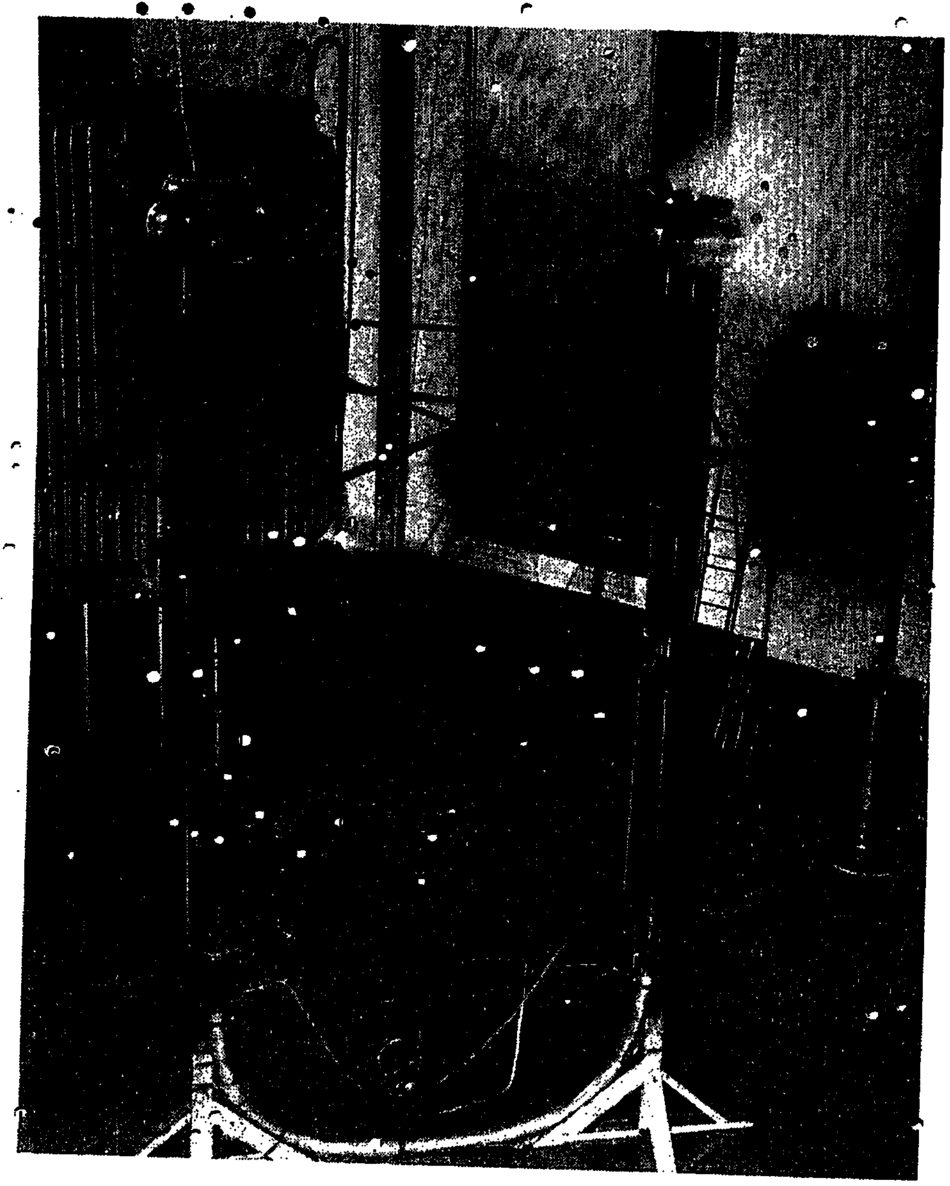

Fig. 12. Breakdown test on 220-kv. cable

filled cable as compared with the solid type have proved beyond doubt that the insulation thickness of cables for certain voltages can be reduced one-half while still maintaining a very high factor of safety, and with complete freedom from insulation failures; in fact, the present 132-kv. oil filled cables have slightly less insulation than have been used in this country for 66-kv. cable of the ordinary type. Furthermore, for the past year the Commonwealth Edison Co. of Chicago has had experimental lengths in operation at 132 kv. which have slightly less than 13/32 in. insulation thickness, or the same thickness as standard for 35-kv. cables of the ordinary type. These lengths have had load cycles heating the cable up to 70 deg. cent., and have performed even better than expected; in fact, the power factor and ionization which have been periodically measured have improved in service.

While at the present time there is no 220-kv. cable in service there is no question about the possibility of manufacturing and operating such cable when needed. The knowledge and experience gained on oil filled cable in service, on field tests and in the laboratory have demonstrated that without doubt, 220-kv. cable can be made to operate with as high a factor of safety as 132-kv. cable, without exceeding dimensions that are entirely practical. In so far as joints are concerned, the development of the condenser type joint with complete control of the distribution of stress makes it possible to design a joint with reasonable dimensions which will be as safe at 220 kv. as the present condenser joints are at 132 kv. The terminals will present no problem, and of course the external equipment such as reservoirs will be essentially the same as that in use at present.

A breakdown test made on a sample of 220-kv. cable is shown in Fig. 12. This cable was tested starting with 250-kv., 60 cycles between conductor and lead, the voltage being raised 25 kv. at one-minute intervals, up to 500 kv., and was held there for 10 minutes. The voltage then was increased by the same steps up to 675 kv., when an arc occurred to the building. A later test was carried to 725 kv., without failure of the cable or terminals. The series of condenser type terminals is of interest, each of three sections having been especially assembled to meet the extreme test conditions imposed by these high values of voltage. It is believed that this is the highest voltage ever applied to a cable.

## Carrying Capacity as Affected by Dielectric Loss

The curves in Fig. 13 are of interest and are self-explanatory. It will be seen that power factors which are obtained at the present time do not cause any serious loss in carrying capacity of cables in existing ranges of voltage. An examination of the curve for 330 kv., however, indicates that there will be some very difficult problems to solve in order to avoid undue reduction of carrying capacity due to dielectric loss when cables at this extreme voltage are required.

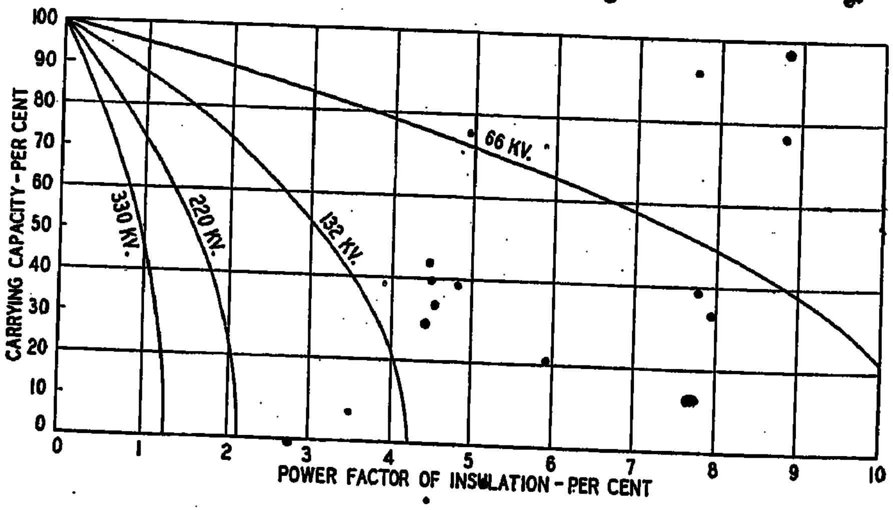

Fig. 13. Carrying capacity of oil filled cable as affected by dielectric loss. Capacity expressed in percentage of maximum possible

Curves are calculated on the basis of a 2,000,000-cir. mil single-conductor cable with one circuit per duct bank

## Future Trends

The road of a prophet is one of great difficulty and should be approached with caution. There are, however, some quite definite tendencies and trends apparent in the cable industry which has already entered a rather revolutionary stage. An illustration of the remarkable improvements that have been made by the cable manufacturers hand in hand with the utilities is the fact that in a short period of about six years from about 1921 to 1927, the maximum operating voltages of underground cables increased successively from 27 kv. to 33 kv., to 45 kv., to 66 kv., and up to 132 kv.

What made the last step possible and what makes still further progress possible is the advent of the oil filled cable idea. It should be emphasized that the oil filled cable has shown not only an ideal solution of all high voltage cable problems but it has demonstrated clearly the fundamental cause of early difficulties. It was well known that cable troubles from defective insulation, when they occurred, usually were due to deterioration caused by ionization and voids in the insulation. The writer does not believe, however, that there was any general appreciation of the fact that these voids were caused by the expansion and contraction phenomena of the cable compound with load cycles. The oil filled cable system is a complete cure to all these difficulties; however, now that the cause of the trouble has been thoroughly understood, cable engineers all over the world are searching for other solutions. If something could be placed in a cable which would expand and contract as the compound contracts and expands, void formation might be minimized. There is a multitude of new ideas on this subject, based on the fundamental idea that it is as illogical to make cables as they have been in the past as it would be to make a large bridge without an expansion joint.

Out of these many ideas involving large scale research, some practical results will doubtless evolve. In the opinion of the writer, the real oil filled cable will continue to be the ideal form. This is said primarily because not only does the oil filled cable completely take care of expansion and contraction phenomena of oils, but an oil filled cable has a degree of initial perfection that probably cannot be attained with any other form. Whether some of the special forms mentioned above will be economically justified in the middle-voltage range has yet to be proved.

Along with important developments in rubber and varnished cambric, undoubtedly the greatest future development will be in the increased economy with oil filled cables at present voltages, due to the reductions in insulation thickness and in cost of accessories which would make possible its use at lower voltages. At the same time we shall see oil filled cables at higher and higher voltages.

---

# Time Factor in Telephone Transmission

By
O. B. BLACKWELL
Fellow A.I.E.E.
American Tel. & Tel. Co., New York, N. Y.

**Although the time factor in telephone transmission has been discussed in several technical papers, there seems to have been none giving a general over-all picture of the subject. Such a picture is presented briefly in this article.**

RAPID EXTENSION of the distances over which commercial telephony is given and the introduction of long telephone cables have introduced time problems in telephone transmission which are of great difficulty and technical interest.

The more important of these problems are the following: (1) The slowing down of conversation by the time interval between the formation of a sound by the speaker and its reception by the listener; (2) distortion of speech by the differences in the speed of transmission of the different frequencies which form it; (3) echo effects which arise from the reflection of energy at points of irregularity, particularly at the ends of a circuit; (4) interference with voice operated devices which may be connected in a circuit to overcome echoes or to stabilize the circuit; and (5) fading in radio circuits which may result from the different times of transmission of the signals over separate paths between the transmitter and receiver. This last matter, however, is outside the discussion of the present paper which is confined to the conditions where not more than one path is involved in the transmission in either direction.

The speed of transmission in which we are interested in this paper is that at which signals pass along the line. This may be quite different from the speed at which the crests or troughs of the waves travel along the line when a single frequency potential is applied continuously at the sending end. In fact in some forms of artificial circuit the crests and troughs may travel toward the sending end.

---

Based upon "The Time Factor in Telephone Transmission" (No. 31-135) presented at the A.I.E.E. South West District meeting, Kansas City, Mo., Oct. 22-24, 1931.

## Table I—Speed of Transmission

| Type of circuit | Approx. speed miles/second |
|---|---|
| Cable circuits loaded with 88-mh. coils at 3,000-ft. spacing. | 10,000 |
| Cable circuits loaded with 44-mh. coils at 6,000-ft. spacing. | 20,000 |
| Cable pairs of non-loaded 16 B&S gage | 130,000 |
| Non-loaded open wire pairs | 180,000 |
| Radio | 186,000 |

Since the speed of signal transmission is generally different for different frequencies, we must consider at a time only a single narrow frequency range. We may suppose for convenience that electrical filters are applied to the circuit so that only frequencies within this narrow range can be effectively applied to it. If a voltage having a frequency, say, at the midpoint of this narrow range is applied to the circuit for a short interval and then removed, the speed at which the disturbance thus set up travels down the circuit is the speed in which this article is concerned. A spurt of energy of this type is evidently similar to that which takes place in a carrier telegraph system when a dot impulse is applied to the circuit.

On this basis the approximate speeds of a number of standard constructions which represent good engineering practise today are given in Table I. These figures are for bare circuits. In actual circuits the speeds are reduced 10 to 25 per cent by the apparatus necessarily inserted at the terminals and at intermediate points along the circuit.

Considering the first of the time problems listed above—that is, the slowing down of telephone conversation—it may be noted this does not interfere with one-way transmission. It does, however, slow down two-way conversation by the time required for the transmission of a question to the distant end and the time required for the return of the answer. Non-loaded open-wire, non-loaded cable, and radio are all sufficiently fast so that this effect does not interfere with their use for telephoning between any two places in the world. In fact this problem is not a pressing one for the largest distances within the United States even with loaded construction of the types now standard for long circuits. We must consider in the future, however, the joining together of long lengths of cable in this country and long lengths in Europe with possibly long lengths of intervening submarine cable. If two persons talked over a circuit of such great distances with the present types of loaded toll cables, each would feel that the other was somewhat sluggish in his replies.

Tests have been carried out to determine what magnitude of delays is permissible. Several methods of conveniently introducing delays have been employed in these tests. The method found the most useful is that illustrated by Fig. 1.

Two long brass pipes looped back and forth to conserve space are equipped with loudspeakers at their ends. One of these pipes is connected by means of its loudspeakers into the circuit for transmission in one direction, while the other is connected for transmission in the opposite direction. At the sending end of each pipe the loudspeaker converts the electrical energy into sound energy, and at the receiving end of the pipe the loudspeaker reconverts the sound energy back into electrical energy. Amplifiers and other control devices are used to give the desired transmission efficiency and to conserve the wave form. As great a time interval is required for 75 ft. of such transmission through air as for radio transmission half way around the world.

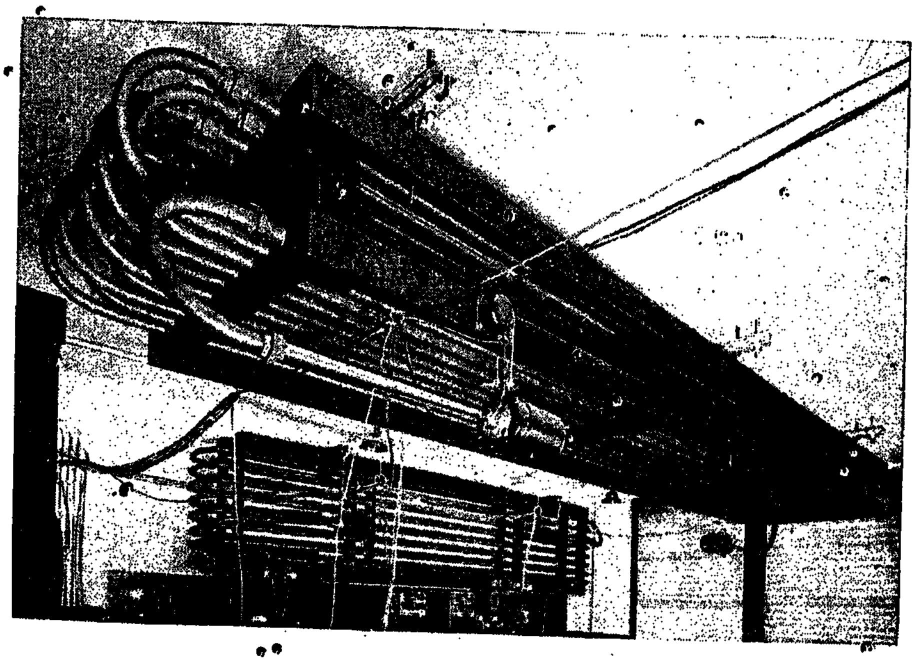

Fig. 1. Experimental acoustic delay circuit

Using devices of this nature, experimenters have found it possible to talk fairly conveniently over circuits representing time intervals as great as 0.7 sec. in each direction. Such great delays, however, would be considered undesirable for commercial use. Generally, delays of about one-third of this are considered the maximum which is satisfactory.

The second problem noted above is the distortion produced when the different frequencies making up speech are transmitted with different velocities. These effects may occur in one-way circuits as well as in two-way circuits and are not related to echo effects. The appearance of these transients to the listener depends on whether the excess delay is at low or high frequencies. It is rather difficult to describe the characteristic sound of a circuit with low-frequency delay. High-frequency delay, if extreme, sounds as though a high pitched reed, such as a harmonica reed, was being plucked whenever a sudden transition occurs in the voice sounds.

The appearance of such transients is shown conveniently by the aid of oscillographs of spurts of alternating current taken before and after being sent over circuits having various delay characteristics. If a frequency $f$ is suddenly applied to the sending end of a line, and if all frequencies are transmitted over the line with the same attenuation and at the same speed, the wave at the receiving end will duplicate exactly in form the wave at the sending end. Any departure of the line from these ideal characteristics causes transient effects at the receiving end as the incoming wave establishes itself, although ultimately the pure wave of frequency *f* is established.

An oscillogram is reproduced in Fig. 2 showing a spurt of 1,600-cycle current as applied to, and received from, a loaded cable circuit having fairly large delays in the upper part of the transmitted frequency range compared to the delay at lower frequencies. It will be observed that the current at the receiving end consists at first of a fairly low frequency which builds up in both frequency and magnitude to the steady state value. At the end of the spurt the same transient is experienced, but in this case the higher frequency currents which have been delayed more in the line are at the tail end of the train.

Transient effects of a particular type of a composited, loaded 19-gage cable circuit are shown in Fig. 3. The small variations in the zero line of the curves, due to cross-talk and other interferences, should be neglected. The upper line of the figure shows an applied 1,000-cycle current; the second line shows its form as it was received, disclosing transients; and the third line shows it at the reception point after it had been passed through a correcting network applied in series with the circuit. While the delay in the reception of the signal had been somewhat increased as indicated by the displacement of the signal further to the right, the transients at the beginning and ending of the signal are reduced very greatly.

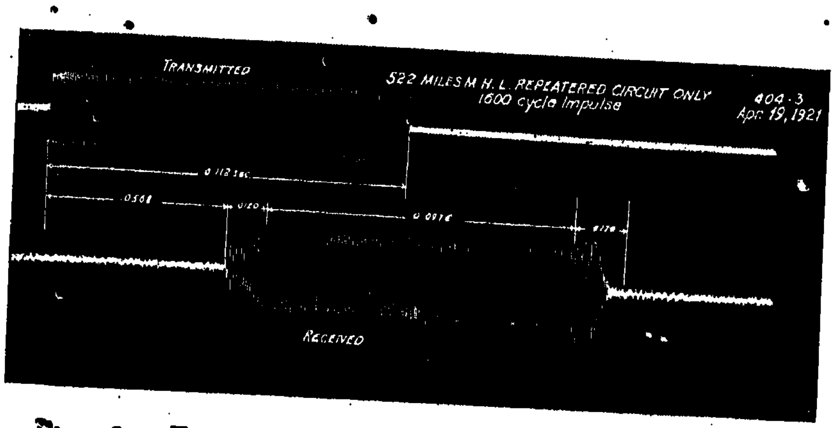

Fig. 2. Transients in medium heavily loaded circuit, showing delays in upper part of the range

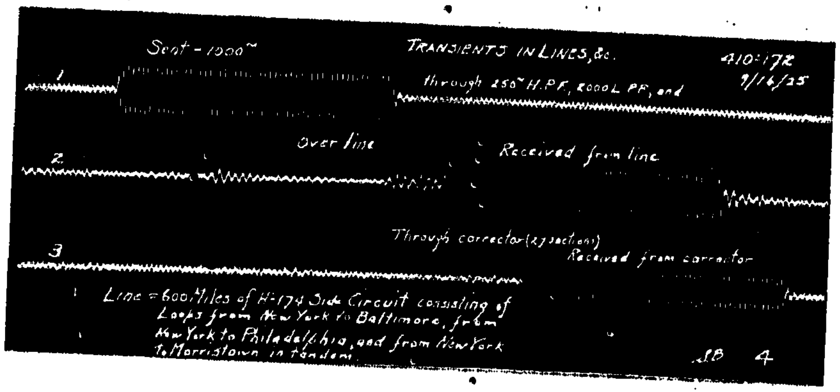

Fig. 3. Transients in medium heavily loaded cable circuit, showing effect of corrector

Excess delay at low frequencies may be present in a circuit due to the apparatus which is inserted in it.

The third problem listed includes the effects of echoes. Reflections of voice waves in all practical telephone circuits arise from impedance irregularities. It is only in telephone circuits of such length as to require a number of repeaters that echo effects become serious. The fact that the circuits are electrically long makes the time lag of the echoes appreciable. At the same time the telephone repeaters overcome the high attenuation and make the echoes louder.

Some of the reflected waves return to the receiver of the talker's telephone and if loud, may give him an uneasy feeling that the distant party wishes to interrupt. Other reflected waves enter the listener's telephone and if, severe, cause him to hear an echo following the directly received transmission.

The simplified diagram of Fig. 4 shows a four-wire circuit in which the effective echoes are limited necessarily to those caused by the two ends, since separate paths are used for east and west transmission. The lower part of the figure suggests the paths which the echo current may follow. The balancing arrangements used at the ends of such a circuit assist of course in keeping down the amount of echoes present.

A form of device used to overcome echoes is indicated in simplified form in Fig. 5. This figure will serve also to illustrate the fourth problem listed above; that is, interference with voice-actuated devices of this kind. The circuit shown is similar to that of Fig. 4 but with an echo suppressor so arranged that energy transmitted in one direction short-circuits and thus disables the path of the circuit going in the opposite direction. In this way echoes from the distant end cannot be transmitted back to the receiving end

If the delays in such a circuit are large and the adjustments not well made, it is possible for one subscriber talking fairly steadily to hold the suppressor operated so continuously that it is difficult for the other party to interrupt even if he so desires. Under similar conditions, if one subscriber starts to reply almost simultaneously with the termination of the other's speech, there may be some clipping at the beginning of his reply by the echo suppressor. More involved difficulties arise when there are two or more such devices at different points in a circuit.

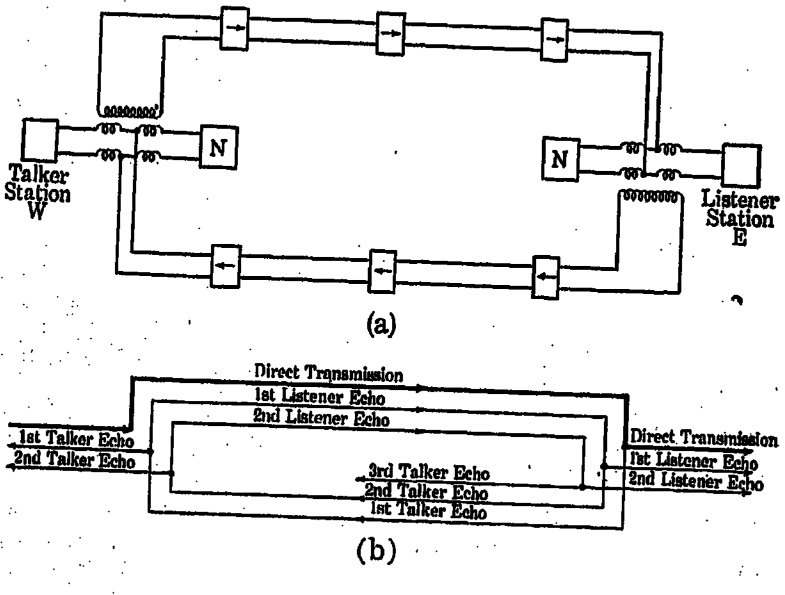

Fig. 4. Diagram of a four-wire circuit

Long radiotelephone circuits may vary so greatly in transmission effectiveness that if they were arranged to be operative in both directions at a time, it would be difficult to prevent their becoming unstable and setting up oscillations. Voice-actuated devices somewhat similar to echo suppressors but more elaborate are therefore employed on such circuits to stabilize them. With this arrangement the circuits leading to both radio transmitters are normally disabled. The speech waves starting from either end, therefore, must operate devices to put the transmitter at that end into working condition and to disable the receiving circuit at that end. Evidently arrangements of this kind need even greater care in design and adjustment to prevent clipping of speech and to avoid making interruption by the listener difficult.

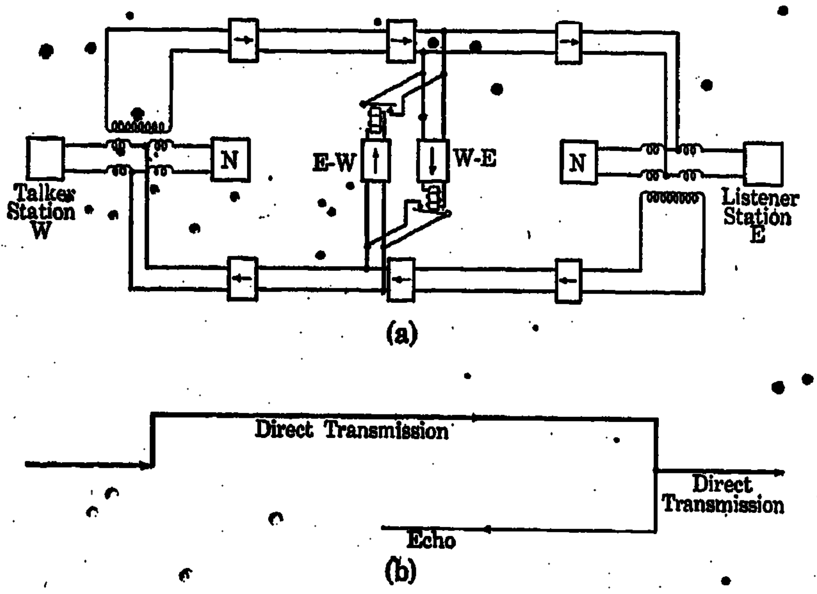

**Fig. 5. Four-wire circuit with echo suppressor**

An interesting application of time delay has been made in connection with radio systems so operated. In this the voice currents on reaching the disabling point are passed through an artificial line in which a desired amount of delay is incorporated. Just before entering this line a part of the energy is taken, rectified, and made to operate the switching mechanisms for restoring the circuit to operating conditions. This switching is completed by the time the voice currents have passed through the artificial delay circuit and are ready to proceed down the line. If it were not for this arrangement a small part of the speech currents might be lost during the interval while the switching mechanisms were operating.

## BIBLIOGRAPHY

In preparing the following classified bibliography, no attempt has been made to make it complete. It is believed, however, to contain most of the important publications on the subject.

# Electrical Precipitation

**Although Cottrell smoke precipitators have found application in a variety of industries, theoretical features of the process and fundamental laws underlying it have not been subjected to very close scrutiny. Experiments described here were made to determine the effect upon "precipitation efficiency" of many of the variables entering into the process.**

By

COTTRELL TREATERS have found many applications in various industries for the recovery or removal of smoke, dust, and fume particles from their containing gases; yet the fundamentals of the process have received but scant attention. In order to put this process on a more quantitative basis an experimental and theoretical study was made in this laboratory, in which were investigated the effects upon the *precipitation efficiency* or percentage removal, of various fundamental variables such as the operating voltage, secondary current, gas velocity, concentration of the dispersoid, size of discharge electrode, and other factors.

The underlying theory of the process has been covered in previous publications, but for the purposes of this article, the following is quoted from "Electrical Precipitation of Solids from Smelter Gases," by Ross B. Rathbun, A.I.E.E. Trans., V. 41, 1922, p. 816:

> "This (the precipitation) is accomplished through the ionization of the gas which carries the particles in suspension. It is assumed that the negative ion or electron is the ionizing agent and that the velocity of the electron stream is sufficient to ionize the gas molecules by collision in a relatively small zone near the discharge electrode where the potential gradient is steepest. This stream of electrons in making its way toward the opposite electrode is assumed to charge the minute dust particles in passing by contacting or attaching to the particles. The latter having acquired a negative charge, and being in a strong electrostatic field, are attracted by the positive pole and hurled against it with considerable force, where they give up their negative charge to this electrode and cling to it (the electrode) by adhesion."

Thus the process may be seen to consist simply of passing the fume-laden gas through a unidirectional electrostatic field in which a corona discharge is maintained. The dust particles first are charged by the electric field and then swept out of the space between electrodes.

The theoretical development of the present article was based upon the assumption that the chance of a particle being precipitated depends merely upon its chance of encountering an ion, and this led to the equation

$$\eta = 1 - e^{-\alpha t} \tag{1}$$

where $\eta$ is the percentage removal (expressed as a fraction) $t$ the treatment time, $\alpha$ a constant for a particular precipitator treating a given fume or dust, and $e$ the base of the hyperbolic system of logarithms. This equation enables an immediate deduction of the effect of the distance $L$ traversed by the gas in the precipitator and the gas velocity $V$, since the time $t$ is merely the quotient of these two. This leads to the equation

$$\eta = 1 - e^{-\frac{\alpha L}{V}} \tag{2}$$

From eq. 1 also the effect of increasing the effective cross-section of a treater or its length, or the equivalent process of connecting similar treater units in parallel or in series, can be deduced immediately. Since time $t$ is the only variable factor appearing in the right-hand member of eq. 1, for a given constant gas volume treated per minute in a given number of precipitators, how these are connected has no import as regards the resulting efficiency, for the length of path is increased in a series connection in the same ratio as the velocity

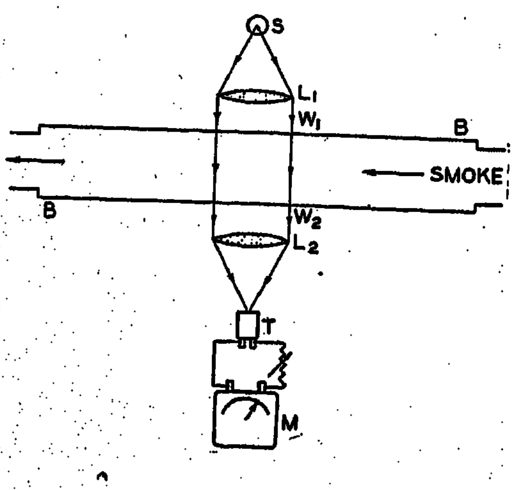

**Fig. 1. Special photometer for determining smoke concentration**

---

From "Some Fundamental Theory and Experiments on Electrical Precipitation" (No. 32-32) presented at the A.I.E.E. winter convention, New York, Jan. 25-29, 1932.

is decreased in a parallel connection. In other words, a given number of units can be connected all in series or all in parallel without any difference in the theoretical efficiency. The same holds for symmetrical series-parallel connections.

## SPECIAL APPARATUS DEVELOPED

One of the chief difficulties in experimenting with the action of the Cottrell treater has been the lack of a quantitative method of determining the instantaneous dust or smoke content of the gas entering or leaving the precipitator. In these experiments this difficulty was solved by means of an optical (photometer) method; specifically, by measuring the light absorbed by a definite column of the smoke-laden gas. For a dust of constant composition and physical characteristics it can be shown that the concentration is proportional to the logarithm of the ratio of the incident to the transmitted light. The factor of proportionality depends upon the nature of the dust or smoke to be measured.

Apparatus used for measuring the dust concentration is shown schematically in Fig. 1. Light coming from small lamp $s$ is rendered parallel by the lens $L_1$, then passes through the window $W_1$ into a long rectangular box $B$ carrying the smoke-laden gas; from a second window $W_2$ on the other side of the box the light emerges, reduced in intensity by a fraction depending upon the concentration of the smoke; then by means of a second lens $L_2$ the light is concentrated on a light-sensitive element which sends a current through the meter $M$ proportional to the intensity of light acting upon it. Two such metering devices were used, one on the inlet and the other on the outlet side of the experimental precipitator.

The experimental precipitator used is shown diagrammatically in Fig. 2. It consists essentially of a cylinder (pipe) with an insulated wire electrode stretched inside along its axis. The wire is held in place by heat-resisting glass insulators at either end, the necessary corona-forming potential being supplied by a lead brought into the cylinder through a bushing also of heat-resisting glass. The high voltage supply consisted of a pulsating direct current obtained from a half-wave vacuum-tube rectifier.

For the material to be precipitated oil smoke was used, this being generated by a specially designed "smokifier" which allowed the formation of a constant stream of smoke of constant characteristics. This device consisted merely of a copper U-tube immersed in a molten lead bath; smoke was formed by simply feeding a thin stream of oil into the hot tube; the resultant smoke was blown out by a stream of air. Strictly speaking, this device generates an oil "mist" rather than a true smoke, the oil itself not being carbonized but merely vaporized and recondensed in the precipitator.

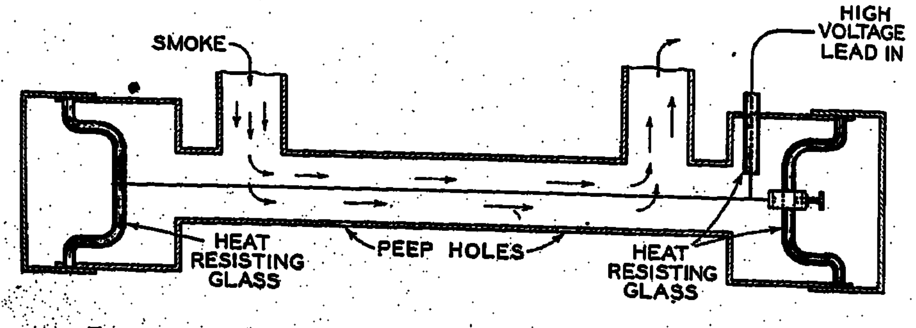

**Fig. 2. Cottrell electrical precipitator used in the experiments of this article**

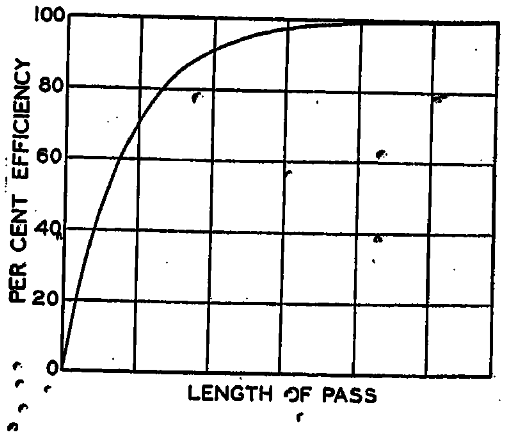
Experiments were carried out by passing the oil smoke first through one of the specially designed optical photometers where its initial concentration was observed; next the smoke was passed into the precipitator to which variations in the different factors involved in the investigation were applied. From the precipitator the gas was piped through a second optical photometer where its final concentration was observed.

## RESULTS

In general the experiments showed that the precipitation efficiency increases with the treatment time, voltage, current, and power, according to a curve which partakes of the nature of that for a condenser charge; or, in other words, they are exponential relationships. Curves representing these relationships thus rise steeply at first but at a continually decreasing rate; then bend over and eventually approach the value of 100 per cent efficiency asymptotically. This is depicted graphically in Fig. 3, which is a theoretical curve of the precipitation efficiency plotted as a function of the treater length. For a given gas volume treated per minute or constant gas velocity, the treater length is proportional to the treatment time. From this curve it may be seen that in general the cleaner a gas becomes the harder it is to make it still cleaner. After the first 90 per cent of the smoke particles has been removed, just as much additional apparatus is required to remove an additional 9 per cent of the original content than was necessary to remove the first 90 per cent, and so on. From the theoretical point of view this is due to the fact that the cleaner the gas becomes (that is, the smaller the concentration of the dispersoid) the smaller becomes the chance of a single particle of the dispersoid encountering an ion.

**Fig. 3. Theoretical precipitation efficiency of a Cottrell treater as a function of its length**

Curves for electrode voltage and current would have similar shapes



In addition to the general results just outlined, certain other peculiarities of importance were noted. Surprising as it may seem, the value of the operating voltage, in so far as it determines the electric field, apparently has but little effect upon the cleaning efficiency. The function of the field is only to sweep the particles, once they have become charged, to the collecting electrode; for this purpose over a wide range the exact value of the field and consequently of the applied voltage is of secondary importance. The same holds for the size of the discharge electrode; the latter merely determines the operating or corona-forming voltage.

Of fundamental importance, however, is the current flowing between electrodes and through the smoke-laden gases within the precipitator; and for different discharge electrodes and operating voltages it was found necessary only to duplicate the current to duplicate the precipitation efficiency. The current itself is affected by the concentration of the dispersoid entering the precipitator, being considerably depressed if the concentration is high, and *vice versa*. The resulting corona characteristic (current-voltage curve) of the precipitator under load thus depends upon the concentration of material entering the precipitator.

While the present theoretical and experimental study, upon which this article is based, is thought to be more extensive perhaps than most others that have been made before, it is considered to be still far from complete. It is hoped that the experiments described and the experimental methods developed will stimulate further research in this highly interesting field.

# Stability Experiences with Conowingo Hydro Plant

By

R. A. HENTZ
Fellow A.I.E.E.

J. W. JONES

Both of the
Philadelphia (Pa.)
Electric Company

**During the first year of operation, four cases of instability developed at Conowingo hydroelectric station of the Philadelphia Electric Company when faults occurred on the transmission lines. Subsequent investigations showed that some of the generators would advance 180 deg. ahead of the system in less than 0.3 sec. when full load was dropped suddenly. Installation of higher speed relays and circuit breakers together with changes in the operating set-up, have corrected the situation.**

STABILITY of electric power systems is becoming of more general interest and concern since the advent of large hydroelectric stations located at considerable distances from their loads, and with the general interconnection of large capacity power systems. Many papers and articles dealing with methods of calculating stability have appeared; but comparatively little information has been published showing the experience on actual systems. Such experience is of value as an indication of what may occur on other systems of similar character and also in determining the basis for design of new projects.

A typical example of a generating station susceptible to instability under certain conditions of severe line faults is the 252,000-kw. Conowingo hydroelectric station which is situated 58 miles from the main system of the Philadelphia Electric Company and ties in with that system and the 220-kv. Pennsylvania-New Jersey interconnection by means of two 220-kv. lines. During the four years the plant has been in service, studies of the stability of this system have been made, and considerable operating experience has been obtained including several cases of instability. As a result several changes have been made to improve system performance. Automatic oscillographs to record system performance during faults are installed permanently, and a great many records have been obtained. No operating tests to determine stability have been made, though several short circuit tests were conducted on the 220-kv. system to determine high speed relay and oil circuit breaker characteristics, these being intimately associated with stability.

### EXTENT OF SYSTEM INVOLVED

The system involved (see Fig. 1) consists of the Conowingo hydroelectric station with seven 36,000-kw.

---

Based upon "Stability of Conowingo Hydroelectric Station of Philadelphia Electric Company System" (No. 32-25) presented at the A.I.E.E. winter convention, New York, Jan. 25-29, 1932.

generators connected by two 58-mile 220-kv. lines to Plymouth Meeting substation, a junction for two lines of the Pennsylvania-New Jersey 220-kv. interconnection, and for connection with the main part of the Philadelphia Electric system through step-down transformers. Three 10-mile 66-kv. aerial lines connect from Plymouth Meeting to Westmoreland substation, from which point lines radiate to the main part of the Philadelphia Electric system where most of the Conowingo output is used.

Pennsylvania-New Jersey interconnection as indicated consists of 220-kv. ties between the Philadelphia Electric Company system at Plymouth Meeting, the Pennsylvania Power and Light Company system at Siegfried, and the Public Service Electric and Gas Company system at Roseland. The interconnected systems are all of large capacity, having respective peak loads in 1930 of: Philadelphia Electric Company, 699,000 kw.; Public Service Electric and Gas Company, 540,500 kw.; and the Pennsylvania Power and Light Company, about 350,000 kw.

## PRELIMINARY STABILITY STUDY

Extensive stability calculations and studies were made before the 220-kv. system was built to check stability in case of line faults. The faults were assumed to involve only one phase since information then available indicated this to be the general experience on 220-kv. systems. These studies were based on the ultimate system development which involves extension as shown by the dashed lines in Fig. 1. Since the system is rather complicated, one of the studies was made with a mechanical model.[2] (For numbered references see bibliography.)

Results of the stability studies showed that in general synchronism could be maintained for practically all expected fault conditions, although considerable swinging was indicated for some conditions. On account of this swinging condition together with uncertainty regarding some of the factors assumed in the study, such as clearing time and fault resistance, it was considered advisable to incorporate in the design several special features for increasing stability.

Measures provided with the initial design, for increasing stability and reliability, may be divided into two general classes: (1) preventive and (2) remedial. The first class aimed to prevent faults by means of heavy insulation and protection against lightning with double ground wires for each line, shielding for substation structures, and installation of lightning arresters at the substation.[3,4] The second or remedial class included steps to clear faults quickly should they occur, and measures to stiffen the system in case of transient disturbances. In this connection a special relay system designed to clear all faults with minimum delay was installed. Oil circuit breakers used were designed to interrupt fault current in less than 0.5 second; at the time of their installation these were the fastest available

for such high voltage service. The generators were built with as low transient reactance as possible consistent with reasonable cost and efficiency. To obtain low reactance in these machines was rather difficult because of their slow speed (80.8 r.p.m.) but it was possible to reduce the transient reactance to about 29 per cent and still have a fairly well-balanced design. Transformer reactance was kept as low as was possible with safety, and this resulted in a value of about 9 per cent. The Plymouth Meeting transformers were so arranged that the synchronous condensers connected to their tertiary windings would be closely coupled to the 220-kv. system in order to secure maximum benefit from them in maintaining stability.

One 30,000-kva. condenser is provided for each of the three transformers at Plymouth Meeting, and these condensers have rather special excitation as described in a previous publication.[5] In case of a system disturbance the exciter voltage is increased automatically at a rate of over 6,000 volts per second, and the load on each condenser increases from a normal value of 10,000 kva. to about 58,000 kva. in 0.5 sec. Two additional condensers with automatic high speed excitation are installed at Westmoreland substation and the 60-cycle motors of many frequency converters on other parts of the Philadelphia Electric system are used as condensers, all of these being provided with automatic voltage regulators. Conowingo generators have special high speed excitation, designed to prevent a drop of more than 2 per cent in their induced voltage when full-load lagging reactive kva. is applied suddenly while carrying full rated load at unity power factor.

### INSTABILITY EXPERIENCED WITH INITIAL OPERATION

During the first year (1928) three faults, all caused by lightning flashovers, occurred on the Plymouth Meeting-Conowingo lines; each fault involved two phases instead of only one as expected and assumed as the basis for design. Conowingo became unstable for each of these faults and also on one other occasion when a severe disturbance occurred due to an oil fire and explosion along the Chester-Schuylkill lines of the 66-kv. system. (See Table I.)

This experience during the first year, when every fault on the Plymouth Meeting-Conowingo line caused instability, naturally was very alarming and extensive study was given to determine the cause of the trouble, and to ascertain what could be done to correct the condition. The study was handicapped at first by a lack of definite records of the time and sequence of events. Some doubt existed regarding the performance of relays, switching time, and operation of the governors. In addition, all four cases of instability occurred before the installation of synchronous condensers was complete and before the high speed excitation system was working satisfactorily.

While practically no interruption of service to customers resulted from these disturbances, it was realized that something must be done immediately to increase the reliability of Conowingo station, therefore a number of temporary measures were adopted pending the outcome of further study and experience.

It was evident that most trouble was likely to occur during lightning storms; also that service to the customer could be maintained by providing sufficient steam reserve. Arrangements were made therefore with station attendants and line patrolmen to watch for electric storms, and to report their appearance to the system load dispatcher; the load on Conowingo then could be reduced and the steam reserve built up. A practise also was adopted of operating the 220-kv. system split so that Conowingo would operate in two separate sections during storms if four or more generators were running. While this meant the certain loss of half the station with a fault on either line, it greatly reduced the chance of losing the entire station. Use of this storm set-up was discontinued in 1931 when changes had been made in some of the equipment so that it no longer was required.

## SPECIAL TESTS

While relief was obtained by the temporary measures just outlined, a series of tests was made to check practically all uncertain factors affecting the performance of the system. The most comprehensive of the tests was a series of single-phase and two-phase faults made at various locations on the Plymouth Meeting-Conowingo lines, records being obtained on all parts of the system by observers and special recording equipment. These tests were made with most of the synchronous equipment and lines in service, but without load because of the danger of disturbing customers. A total of 29 oscillograph elements were used in the test, connections to these being shifted to measure various quantities for the different faults. High speed moving pictures were taken of all faults and of the governors on several generators.

Principal conclusions from this series of tests were as follows:

1. Relay operations were correct and all faults were cleared with more than sufficient margin to prevent the disconnection of any equipment other than the line faulted.
2. Over-all clearing time for faults including switching and relay operation was somewhat longer than expected, averaging a little over 0.5 sec. for the first switch and 1.0 sec. for the second switch.
3. No serious swinging of one Conowingo generator against another was observed.
4. No hunting of governors occurred.
5. Faults were apparently of low impedance and did not "blow" from one conductor to another.
6. The high speed excitation system was not performing as well as expected.
7. Calculated short-circuit currents were in reasonably close agreement with actual test values.

Another test which was made consisted of opening switches on the Conowingo generators while the machines were carrying load. This was done to ascertain the speed characteristics and governor response of these units as well as furnish a service check of the overspeed and overvoltage protection. This test showed that the speed increased so rapidly when full load was dropped that some of the units advanced 180 deg. ahead of the system in less than 0.3 sec. This naturally explains how the plant can get out of synchronism so quickly when the electrical output is reduced seriously by the voltage reduction caused by a severe system fault.

Special tests were made also on the synchronous condensers under load conditions to check the operation of the high speed excitation system and to determine the best adjustments; after some changes had been made, performance was brought up to expectations. The test on the Plymouth Meeting condenser is described in a previous publication.[5] Still another test was the measurement of zero sequence reactance of the Conowingo lines. This consituted one of the uncertain factors assumed in the calculations; the test showed that the measured value was in close agreement with that used in the calculations.

Supplementing the information obtained in the special tests, complete records and reports of each system disturbance are obtained by the following means:

### 1. Automatic Oscillographs

As soon as obtainable, automatic oscillographs were installed permanently at Conowingo and at Plymouth Meeting, a six-element instrument at the former station and a seven-element unit at the latter; most of the time a second six-element oscillograph has been in use at Plymouth Meeting. A four-element Hall recorder is installed at Westmoreland. To obtain records of field experience and special information additional oscillographs

and recorders have been installed temporarily from time to time. These oscillographs record residual current in all lines, power in each of the Plymouth Meeting-Conowingo lines, positive sequence voltage, and selected line currents and voltages. They are started automatically with station residual current, but arrangements are being made to start them also with line current, since three-phase faults recently experienced have had insufficient residual current for this purpose.

### 2. Reports from Station Operators

Most of the relays are equipped with operation indicators and the more important relays are connected to a drop signal system so that it is possible to see which relays operate for each disturbance. Thus usually it is possible to determine the phases which are faulted, and the general fault location. Operators are instructed to note the time of each disturbance and to make a record of all relay operations. They report also indications of maximum reading ammeters in the neutral ground connection of the high voltage transformer windings. Graphic recording meters furnish a continuous record of power, voltage, and frequency. Of course station records are kept which show the system set-up and machines in operation at all times.

### 3. Line Reports

Thorough inspection is made of the line immediately after each fault to determine the damage, location, and number of phases involved.

All available information is collected for each important disturbance and these records are analyzed to determine the cause, number of phases involved, location of fault, fault current, switching sequence, time of clearing, power swings, and other important factors. Records of all severe disturbances have been referred to the major equipment manufacturers to secure their recommendations regarding means of improvement.

In view of the experience with two-phase faults during the first year, further stability calculations were made, based upon this type of fault. These calculations showed that with solid 220-kv. bus operation and heavy load on the plant, a two-phase fault occurring near the end of the line could be expected to cause instability if cleared in approximately 0.5 sec.; however, if the fault was cleared in about 0.15 sec., the system probably would remain in synchronism. A similar study was made for two-phase faults on the Plymouth Meeting-Westmoreland lines; this showed that high speed switching was needed also on these lines.

Equipment manufacturers thought it possible to increase greatly the speed of clearing faults by means of new designs in circuit breakers and relays; and with the need for higher speed operation apparent, they immediately undertook the development of suitable equipment. Some experimental models of new relays and oil circuit breakers accordingly were tested at Plymouth Meeting by means of short circuits on the 220-kv. system. These tests were successful in showing that interrupting time of the order of 0.14 sec. was possible.[6,7]

## EQUIPMENT CHANGES TO INCREASE STABILITY

As a result of the various studies and tests described together with normal development of the system, the following permanent improvements were decided upon:

1. New high speed circuit breakers were provided at Plymouth Meeting and Westmoreland for normal operation on all 220- and 66-kv. aerial lines.
2. The 220-kv. line circuit breakers at Conowingo were rebuilt so that high speed operation was obtained.
3. Relay system was revised and new high speed relays installed on all lines to reduce operating time to about one cycle.
4. A third step-down transformer was installed at Plymouth Meeting.
5. A third 66-kv. line was added between Plymouth Meeting and Westmoreland.
6. The 66-kv. system was split into three separate sections at Plymouth Meeting and Westmoreland.
7. Insulation of the 220-kv. lines was increased from 14 to 16 units for suspension insulators, and from 16 to 18 units for strain insulators.

## OPERATING EXPERIENCES SUMMARIZED

General experience with Conowingo since 1928 has been quite satisfactory. Many disturbances have occurred due to faults on practically all parts of the system, but since the first year of operation when four cases of instability occurred, various steps have been taken to improve operation. As a result there has been only one additional case wherein Conowingo became unstable. The disturbances have been classified according to the location of the fault on the system and are discussed under six general headings.

*Plymouth Meeting-Conowingo line faults.* Principal

data for each fault experienced on the Plymouth Meeting-Conowingo lines are shown in Table I. Some of the information is only approximate but for the sake of completeness it has been included wherever possible.

Fifteen faults including nine single-phase, five two-phase, and one three-phase have been recorded on the Conowingo lines. Instability resulted from the three-phase fault and from three of the two-phase faults which occurred in 1928 before the high speed circuit breakers were in service.

In 1929 no faults occurred while the station was carrying any great amount of load; so there was no real test of stability during the year. At the beginning of 1930, however, there was a rather unusual experience of an electric storm in winter. This caused a lightning flashover of one phase on one Conowingo line while the station was operating with solid 220-kv. bus and loaded to maximum capacity. Very heavy swinging occurred but stability was maintained. An oscillograph record of this disturbance as obtained at Conowingo may be seen in Fig. 3. Clearing time for this fault at Plymouth Meeting is shown by the length of the first step in the residual current record and the clearing time at Conowingo by the total length of the residual current record. Allowance must be made for the starting time of the oscillograph, which in this case was about eight cycles. The record of voltage on the faulted line is interrupted some time before the fault was cleared, due to the operation of an auxiliary switch on the breaker mechanism. The record of current in one phase of the unfaulted line (No. 2 vibrator) shows the surging after the fault was cleared.

The new equipment for high speed clearing of faults was in service in 1931 and showed its value for the first fault of the year which was a flashover of two phases while Conowingo was almost fully loaded. The fault was cleared from Plymouth Meeting in about eight cycles or 0.133 sec. and from Conowingo in 11 cycles as shown by the oscillograph record from Conowingo (see Fig. 4). Time lost between the beginning of the fault and the first visible record is approximately 3 cycles. Rather heavy surging occurred after the fault, but stability was maintained.

The worst disturbance and the only one which has caused instability since the first year's operation was the three-phase lightning flashover of 1931. The plant was carrying 165,000 kw. and the fault was not cleared for almost a full second because there was practically no ground current, and the only high speed relays in service were ground relays. Since this experience, high speed balanced protection has been added to take care of such conditions. Due to the relatively small ground current, the automatic oscillographs did not start until the circuit breaker had interrupted the fault. No definite record was obtained of the clearing time. The record which was obtained (Fig. 5) is of interest, however, since it shows the power swings of the station out of synchronism with the system. The unfaulted line finally tripped as shown by cessation of power swings. The crest of the power swing was used to check stability calculations by comparison with the crest of the power angle diagram calculated for this condition. These check to within a few per cent, which seems to indicate that the assumptions used in the stability calculations are reasonably satisfactory.

*Faults on the 220-kv. Pennsylvania-New Jersey interconnection.* Faults experienced on the 220-kv. interconnection lines running from Plymouth Meeting to Siegfried and Roseland are listed in Table II. So far as known all eight faults were single-phase; while most of these were of relatively long duration, none seriously affected stability. It should be noted, however, that the load on these lines is usually rather small, seldom exceeding 50,000 kw. The Roseland line was not placed into service until near the end of 1930, so that on this line comparatively little experience is available. It was equipped initially with high speed circuit breakers, but the first fault was slow in clearing because it was so near the Roseland end of the line that it was outside the zone of operation of the high speed relays. The next fault which was probably much closer to Plymouth Meeting was cleared in 8 cycles. The last disturbance on the Siegfried line was rather unusual, being caused by failure of the circuit breaker at Plymouth Meeting when the line was being opened. Some material jammed the oil valve connecting one of the switch tanks to the oil system, so that before the breaker was opened most of the oil had drained out without being noticed. Naturally flashover to ground occurred inside the tank. This was equivalent to a 220-kv. bus fault at Plymouth Meeting and was cleared as expected by trip-out of all 220-kv. feeds into that station. This involved considerable time delay, but the system was not seriously disturbed probably because at the time Conowingo was carrying but very little load.

*220-Kv. transformer faults.* Several failures have occurred in the 220-kv. transformers at Plymouth Meeting and Conowingo as shown in Table III. Most of these failures have occurred in the windings, each failure involving only one phase. Synchronism has been maintained through all of these faults, although they were not cleared very quickly and in some cases the station was carrying full load.

*Plymouth Meeting-Westmoreland line faults.* Faults experienced on the Plymouth Meeting-Westmoreland 66-kv. lines are shown by Table IV. Since these lines carry most of the Conowingo output and have considerably higher percentage of reactance than the Plymouth Meeting-Conowingo lines, the matter of line faults is rather serious. Fortunately very few faults occurred there during the first three years when only two lines were in use. The first fault caused both lines to trip apparently due to the relay settings being too low. The next fault occurred when there was but little load on Conowingo, and synchronism was maintained. The remaining faults all occurred in 1931 after the third line had been added and after the new high speed switches and relays were in service. Most of these faults were unusually severe involving two and three phases, and in one case two lines; but they were cleared quickly and stability was maintained in every case.

*Faults on interconnected system.* Faults occur frequently on the Pennsylvania Power and Light Company system, particularly on the Wallenpaupack-Siegfried line.[8,9] However, none of these faults has caused instability at Conowingo even though a three-phase short circuit occurred at Siegfried while Conowingo was carrying full load. This fault lasted for about 52 cycles, reducing the positive sequence voltage at Plymouth Meeting to 76 kv. or about 60 per cent of normal. The maximum swinging of Conowingo power after the disturbance was from about 174 to 334 megawatts. This disturbance was far more severe than generally experienced with faults on the Pennsylvania Power and Light system which usually cause no power surges at Conowingo.

*Faults on Philadelphia Electric main system.* Faults on the Philadelphia Electric 66-kv. system excluding the Plymouth Meeting-Westmoreland lines usually cause but little disturbance at Conowingo. A large part of the 66-kv. system consists of single-conductor underground cable so that most of the faults involve only one phase. These faults sometimes last for more than one second, but there is seldom any trouble except burning of the cable and an occasional tripping of some synchronous motors and converters. A system of pilot wire protection is being installed to reduce the clearing time for cable faults.

One case involving a two- or three-phase fault on the Schuylkill-Chester 66-kv. aerial line in 1928 caused loss of synchronism in some of the machines at Conowingo as described previously. Other cases of two- or three-phase faults have developed on the 66-kv. system since the first year, but none of these has caused instability.

## CONCLUSIONS

Based upon experiences with Conowingo hydroelectric station and with other parts of the Philadelphia Electric Company system described in this article, the following conclusions may be stated:

1. Faults on parts of the system other than the main lines from Conowingo have but little effect upon stability of that station.
2. Single-phase faults on the main lines from Conowingo have no serious effect on stability, but two- or three-phase faults under heavy load conditions are liable to cause instability unless cleared very quickly; faults of this type are likely to occur on the high voltage system.
3. Installation of high speed relays and circuit breakers on the high voltage system has insured the rapid clearing of faults; this practically eliminates the danger of instability except possibly for three-phase faults.
4. System stability may be calculated with sufficient accuracy for all practical purposes, and such studies are essential in system design.

5. Much credit is due the manufacturers for the development of practical methods of studying stability, and for the production of equipment for improving operating stability.

6. Short-circuit tests on the system and special tests on equipment such as that used to obtain high speed excitation fully justify the expense incurred.

7. Permanently installed automatic oscillographs are desirable for: (a) investigating and analyzing conditions when instability occurs; (b) checking calculations of stability limits; and (c) checking relay operations.

# Automatic Combustion Control

**Equipment for the automatic control of combustion in modern steam plants is installed as much to achieve operating speed and simplicity as it is to effect operating economy. Fundamentals of typical systems are outlined here.**

By
**C. H. SANDERSON**
Fellow A.I.E.E.

**E. B. RICKETTS**

Edison Company

THE SUCCESSFUL application of automatic devices to power plant combustion control has been very largely a development of the past ten years. During this period confidence in automatic operation was greatly strengthened by its success in other fields, particularly in that of electric substations and hydroelectric generating stations. Moreover, because of the ever increasing urge for higher efficiencies and lower fuel and labor costs, its development and application has had whole-hearted approval and assistance of engineers and operators.

Earliest attempts at automatic control employed damper regulators actuated by steam pressure. Then, with the development of automatic stokers and forced draft, regulators were applied to blower engines and to the maintenance of balanced or nearly balanced furnace draft. This early apparatus was very crude in its mechanical features, and had the bad habit of being either all "on" or all "off," thus producing a steam pressure chart having frequent and wide fluctuations. The next step in the development was a departure from these unreliable automatic devices in the application of permanent instruments to indicate draft and rate of coal feed, together with better facilities for hand control. Where hand control of the entire plant was centralized, improvement was realized in the uniform loading of the various boilers and in the much closer regulation of steam pressure.

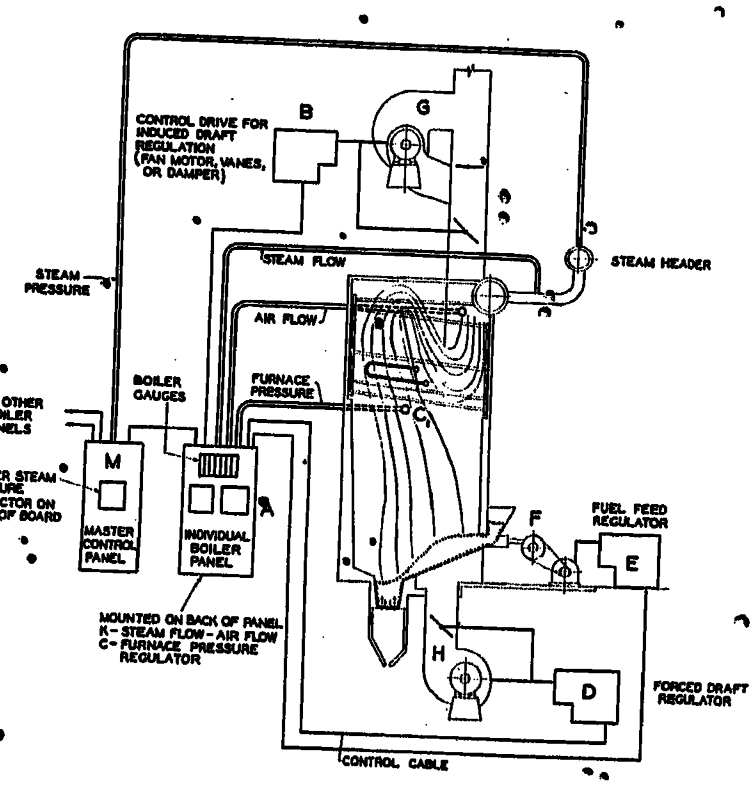
Development of a modern boiler plant necessitates the consideration of large units where, in many cases, the auxiliary equipment may be located a hundred feet or more from the control point. Also, large stokers may be used requiring varying air pressure in their different sections, or gas, oil, or pulverized fuel may be selected and for which efficient operation requires closely coordinated regulation of fuel and air. The necessary complement of gages and meters for a single boiler has been very greatly increased while economic necessity has reduced the number of men. The unit cost of labor and fuel has trebled in the last thirty years and consequently comparatively small savings in these items may justify the expenditure of material sums for new equipment to produce such results.

Another point is the fact that, because of the usually small amount of steam storage, fluctuations in station load almost immediately are reflected in steam demand. If maximum efficiency is to be maintained consistently these fluctuations in demand must be met by corresponding changes in fuel and air supply. When a multiplicity of boilers supply the same steam system, any change in station load normally should be properly

---

From "Automatic Combustion Control," (No. 31-92), presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1931.

divided among all boilers. If the operating force is sufficient in numbers, highly skilled, and supplied with adequate instruments, results can be obtained with a well planned manual control which compare favorably with the best automatic control. However, the automatic control is ever alert to perform its functions. Its chief advantage lies in its ability to act simultaneously throughout the plant, thus permitting a reduction in the required number of skilled operators.



Bailey combustion control system

Large, modern boiler installations commonly are equipped with push-button type of remote control which represents probably the most easily and quickly manipulated type of manually operated equipment. The cost of such a system represents a large portion of the cost of a complete automatic control system, and it may be incorporated as a part thereof.

## ADAPTING THE CONTROL TO THE INSTALLATION

While control systems can be adapted to most any type of boiler auxiliary equipment, the smoothness of operation often is complicated by the inherent characteristics of the apparatus controlled. The ideal combination of control and auxiliary equipment is one which, by delivering to the furnace a proportionately changed amount of fuel and air, gives immediate response to a change in demand. Some types of equipment inherently are capable of approaching this ideal more closely than others and an understanding of such characteristics will be helpful in an understanding of what may be accomplished with automatic control.

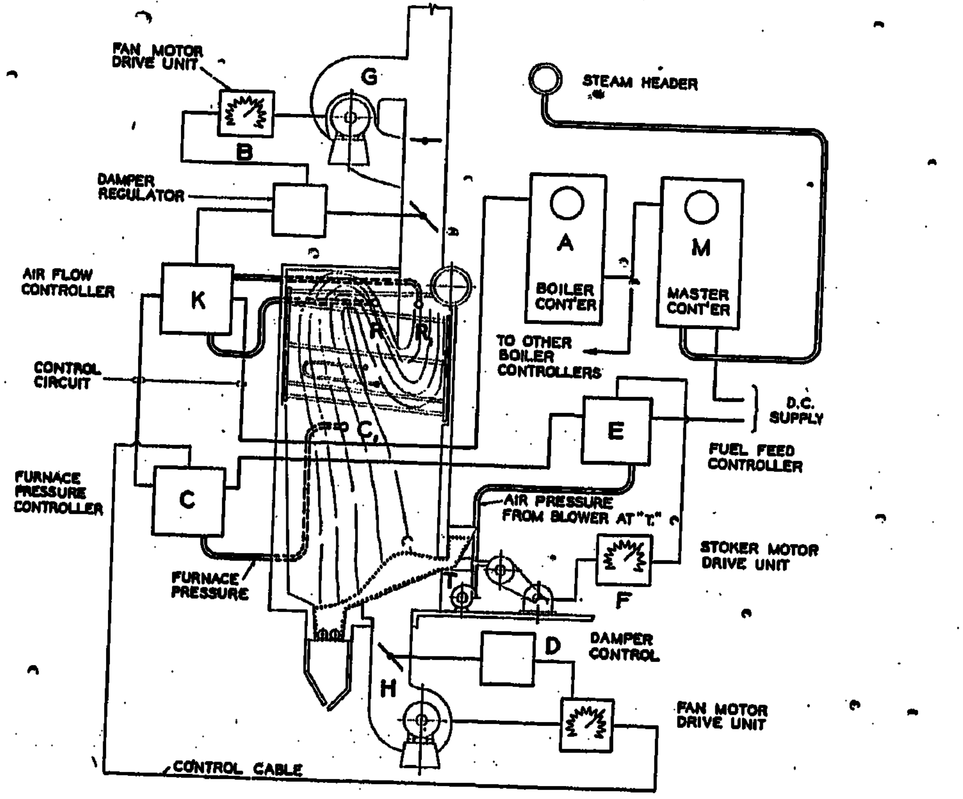
*Air Supply.* Air supply control usually is actuated by draft at the boiler outlet. Some types of draft-producing equipment can be controlled for smooth changes in small increments; others operate with large increments. Among the types of draft equipment producing smooth changes are:

1. Chimney draft—damper control.
2. Steam driven fans—driver control.
3. D-c. motor driven fans—driver control.
4. Wound rotor a-c. motor driven fans—driver control.
5. Single speed a-c. motor driven fans—damper control.

Among the types of draft equipment producing abrupt changes of relatively large magnitude are:

1. Multi-speed induction motor driven fans—driver control.
2. Multi-speed induction motor driven fans—driver and damper control.
3. Multi-speed induction motor driven fans—driver and vane control.

Large, modern boiler installations employing long stokers commonly require a supply of air at several different points at different pressures. This condition makes necessary the provision of several windbox pressure controllers which may be adjusted either for a constant ratio or for varying ratios for the different sections of the stoker as conditions may demand. Similarly, pulverized fuel installations may require individual regulation of the primary, secondary, and tertiary air pressures.



Leeds and Northrup combustion control system

In most systems of control involving the supply of air under pressure for combustion it is necessary to provide an auxiliary control to prevent the occurrence of a furnace pressure above atmosphere. This control is actuated by furnace draft and usually functions as an emergency or readjustment mechanism on the forced draft fan.

Many different types of automatic control are available for application to the different systems used for producing draft or air supply. For example: in natural draft installations the automatic control is usually applied to the stack damper; for variable speed motors and steam turbines the speed of the driver only is automatically controlled; in some pulverized fuel systems employing a unit system, it is necessary to introduce a time lag in the air supply equipment to allow for the interval between the increase or decrease in the coal supply to the mill and the time when this change in supply reaches the furnace.

Enco combustion control system

*Air Measurement.* In a few cases it is possible to measure the air supply by means of an orifice or some other metering device installed in the air supply line. However, and usually because appreciable quantities of air enter through openings in the furnace setting, it is necessary to base the air control on the flow of the gases of combustion rather than upon the air supply. The medium most often used for this control is the pressure drop through a bank of boiler tubes. When the tubes are reasonably clean this method of air control is sufficiently accurate for all practical purposes. When the tube bank becomes partially covered with slag, manual readjustment of the air supply controller is necessary unless an additional control connection is made with some form of $CO_2$ meter to provide automatic readjustment.

*Fuel Supply.* Types of fuel supply equipment have a very marked influence on the quickness of response to a change in load and on the effect of large abrupt changes in draft on combustion conditions. The following types of supply equipment afford immediate response:

1. Gas.
2. Oil.
3. Pulverized coal—bin and feeder system.
4. Stokers carrying a heavy fuel bed.

The following types have a slow response (from one to fifteen minutes):

1. Pulverized coal—unit system.
2. Stokers carrying a light fuel bed.

All types of fuel supply are adversely affected by large, abrupt changes in air supply; the disturbance in all cases being more marked with water-cooled furnaces than with refractory furnaces. The effect on some of the more widely used systems is as follows:

| Conditions | Effect |
|---|---|
| 1. Stokers with deep fuel bed | Smoke and temporary loss in efficiency |
| 2. Stokers with light fuel bed | Blowing bare spots on grates, loss in efficiency and capacity over a considerable period |
| 3. Pulverized coal—bin and feeder system | Possible loss of ignition |
| 4. Oil and gas | Possible loss of ignition |
| 5. Pulverized coal—unit system | Probable loss of ignition |

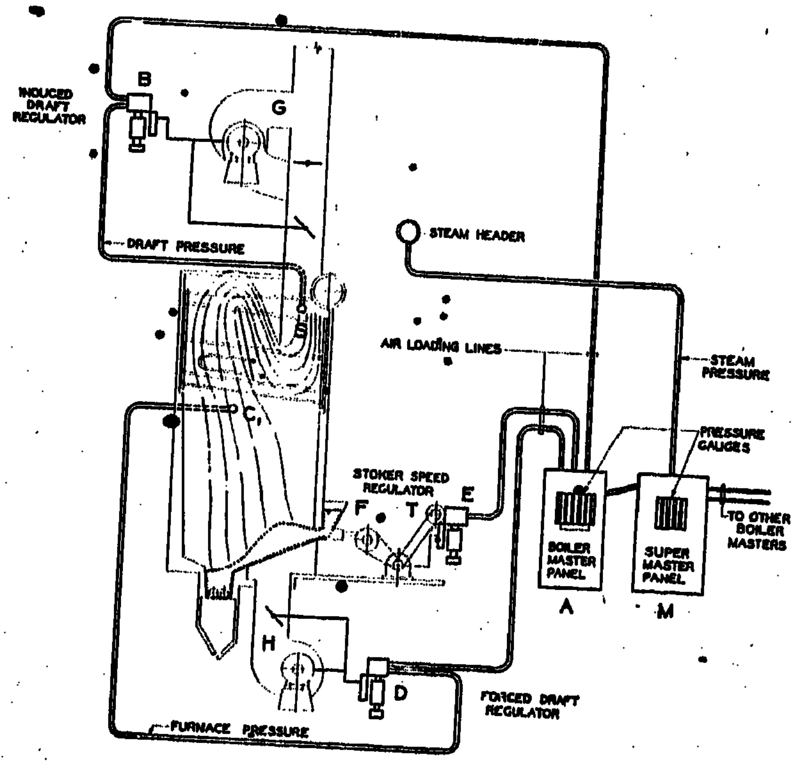
*Fuel Measurement.* Where coal is the fuel, the measurement of supply commonly is derived from the revolutions of the fuel feeding mechanism, each revolution of which is assumed to inject a given quantity of combustible material into the furnace. Unfortunately, however, coal is one of those natural products subject to wide variation in physical and chemical characteristics which variations are reflected in the fuel value per unit of volume. Consequently, correct ratio of fuel and air can be maintained only by occasional manual readjustment of the coal feeding mechanism or by an automatic air adjustment mechanism actuated by a $CO_2$ meter or a steam-flow air-flow meter.

*Sequence Interlocking of Control.* In nearly all large modern boiler installations it is necessary to provide sequence interlocking between certain of the control points. For example: it is usually necessary that a shut-down of the induced draft fan simultaneously interrupts the coal feed and air supply, and that the coal feeding mechanism will not overtravel beyond the ability of the induced draft fan to take away the products of combustion. In many installations firing pulverized fuel there is a low limit of coal and air feed below which combustion becomes unstable and the fire may blow out.

Wherever automatic combustion control is applied, each boiler unit is provided with a simple and ready means for changing from automatic to hand control as may be necessary under such emergency conditions as the whole or partial interruption of the supply of coal, air, or feed water to an individual boiler.

*Control-Power Supply.* To insure continuity in the operation of the control system, the supply of the medium through which the control impulses are carried to the various regulators must be safeguarded positively by the provision of two or more independent sources of supply and a ready means of changing from one source to another. Pneumatic and hydraulic systems originally were employed, but with the advent of electrically operated remote control, electricity has been adopted by many manufacturers as the medium for automatic control. These electrical control drives are designed to use either alternating or direct current at any voltage from 110 to 250.

*Systems.* Probably no two power plants ever built were exactly alike. Comparison of any one with another as regards the detailed requirements of an automatic combustion control system reveals a surprising lack of standardization. Naturally the same is true of the control systems employed, and therefore only a generalized performance specification together with diagrams of several typical systems will be given here.



Smoot combustion control system

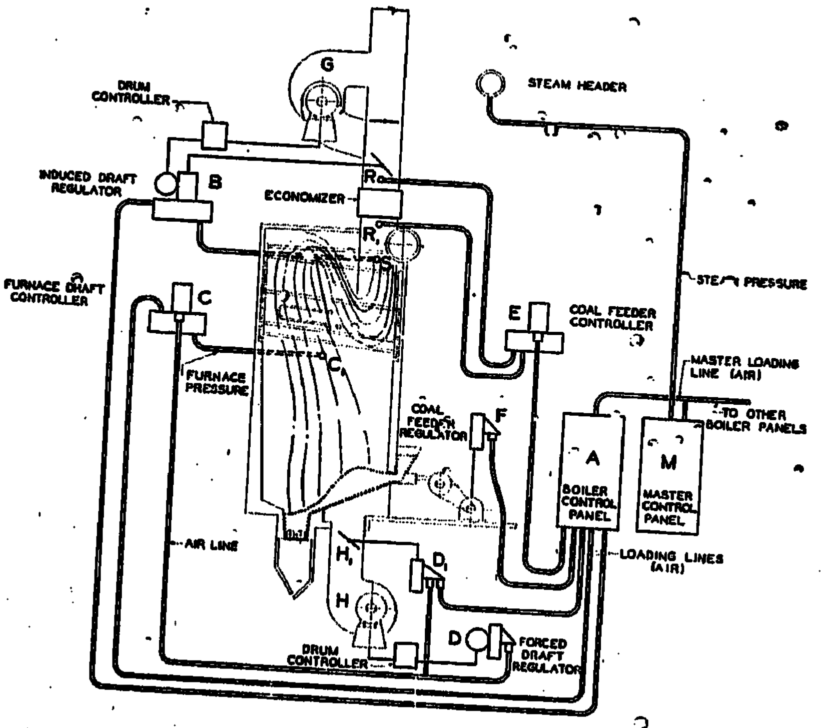
In all systems impulses actuated by variations in steam pressure are transmitted simultaneously to the various individual boiler control panels from which radiate the controls of fuel and draft. The control performance in general is as follows:

1. An increase in plant load causes an increased demand for steam and therefore a drop in steam pressure.

2. Changes in steam pressure are converted into impulses which actuate a regulating device controlling in proportion to the load the rate of fuel and air supply to the boiler. Forces or impulses which are not linear are adjusted in the regulator.

3. Since the regulator can control only mechanical forces which under normal conditions will supply the correct amount of fuel and air, variations from the assumed normal conditions must be compensated for by changing the relation between these mechanical forces which supply either fuel or air so that the correct amount of each is supplied to the boiler. A furnace pressure regulator and a $CO_2$ recorder will detect and make adjustments for variations from normal conditions. These variations are caused by slagging, damp coal, or an irregular supply of coal.

4. Controls can be set so that certain boilers maintain a constant output while other boilers take the variations, and can be provided with maximum and minimum stops to limit the range of output.



Hagan combustion control system

5. Control of any or all functions can be accomplished separately or in groups and either directly or indirectly as required by individual conditions.

6. Some of the available systems are provided with audible and selective visual signals to indicate equipment failure.

## CONCLUSIONS

The question as to what financial return may be expected from an investment in automatic combustion control often is asked. The answer is infinitely more involved than the question. Savings in operating expense as high as 4 per cent have been reported. Rarely, however, has it been found practicable to make comparative efficiency tests on the same installation, operating with and without automatic control, to determine definitely the annual saving in operating expense.

As a rule, automatic control seldom is installed solely on the basis of a direct saving in operating expense. In fact its installation often is based mainly upon resultant operating advantages otherwise difficult or even impossible of accomplishment. Among the more important of these advantages are:

The uniform loading of all boiler units.

Instant response to changes in load.

The supply of fuel and air in correct proportions at all times.

A ready means of providing for safety of operation through sequence interlocking of auxiliary equipment.

# Proposed Definitions of Power System Terms

DEFINITIONS of terms used in stability and interconnection studies have been developed by a special committee functioning since 1930. This subject committee was organized at that time under the auspices of the subcommittee on interconnection and stability factors of the committee on power transmission and distribution, to develop some definitions of terms used in stability studies. Later in the same year, a joint interconnection committee, with F.C. Hanker, as chairman, was formed with representatives from the committees on power generation, protective devices, and power transmission and distribution; and the work of the subject committee was continued under the direction of this subcommittee. Likewise, the scope of the definitions was increased to include terms used in interconnection as well as stability studies. The report of this work is submitted in five general divisions:

1. Interconnection terms
2. Stability terms
3. Active power and reactive voltampere conventions
4. Synchronous machine quantities
5. Response of excitation systems

In the preparation of this report, the subject committee reviewed the technical literature, particularly publications of the Institute, and consulted representative members of the committees of the Institute in order to obtain terms and their definitions which would be in accord with common usage and preferred practise in so far as possible. Attempt has been made to select terms which are descriptive of the subject. The general field covered by these definitions is indicated in the paragraphs following. It is hoped that all interested parties will become acquainted with these definitions and will express themselves freely on controversial points.

## INTERCONNECTION TERMS

In the symposium on interconnections presented at the A.I.E.E. summer convention in Asheville, N. C., June 1931, several interconnection terms were used for the various power quantities which may flow between interconnected power systems. It seems desirable at this time to propose definitions of these terms before too many loose expressions come into general use. In the report, therefore, definitions of terms are presented which are descriptive and cover practically the field in its entirety. The various types of active power and reactive voltamperes are defined.

## STABILITY TERMS

A number of papers with varying phraseology and a resulting confusion of terms have been presented before the Institute on the problem of stability of power systems. The subject committee has endeavored to reconcile the opinions of the several authors into a set of terms and definitions which will satisfy the requirements of power systems and the automatic devices used to control them. After consultation with several of these authors, definitions are recommended for the various stability terms.

## ACTIVE POWER AND REACTIVE POWER VOLTAMPERE CONVENTIONS

The convention of plotting active power and reactive voltampere quantities is somewhat arbitrary and does not depend upon a strict mathematical basis. The plotting of active power usually is taken as positive in the direction of power flow from a generator, but the plotting of reactive voltamperes has not been so obvious. To date, the international committee of the International Electrotechnical Commission, as well as the present subject committee have been unable to reach an agreement upon the convention to adopt. Meanwhile the subject committee presents an arbitrary choice to foster discussion with the understanding that this choice will not prejudice further action. The proposal consists of using the complex quantity $P - jQ$ to represent the active power and lagging reactive voltamperes such as supplied by an overexcited synchronous generator. There has been considerable discussion as to whether or not $P + jQ$ should be used because $R + jX$ represents an inductive reactance.

## SYNCHRONOUS MACHINE QUANTITIES

Synchronous machine quantities are used in calculations for short-circuit currents, relay settings, stability studies, and the like. Both saturated and unsaturated values of these quantities are used in practise depending upon whether currents of very high value or of normal value are involved. The reactances as well as the time constants of synchronous machines are influenced by saturation. Since, in general, saturation effects have not as yet been sufficiently investigated to determine these constants for varying degrees of saturation, definitions are presented applying to any degree of saturation, and methods of determination by test applying to as great a degree of saturation as possible. Where alternative methods of test for reactances are given, care should be exercised in choosing the method for a particular application since they are not equally applicable for all degrees of saturation. A résumé is given of the methods of

---

Excerpts from "Proposed Definitions of Terms Used in Power System Studies" (No. 32M2), being the report of the subject committee on definitions, H. K. Sels, *chairman*, R. G. Lorraine, J. R. North, and C. F. Wagner, Jr., presented at the A.I.E.E. winter convention, New York, Jan. 25-29, 1932.

test for reactances, together with the degree of saturation which readily can be obtained. Attention is called to the added cost that may be necessary in making tests to obtain more accurate synchronous machine quantities for use in calculations of system operating conditions.

### RESPONSE OF EXCITATION SYSTEMS

The development of high speed excitation systems to improve the stability of power systems has created the necessity of expressing the characteristics of the exciter when used to overexcite the main machines. In the report, definitions are proposed which meet these requirements.

While many of the definitions proposed by the subject committee may be considered arbitrary, they have been considered in the best interests of the profession. General adoption of these terms and definitions will lead to a better common understanding with less possibility of confusion and controversy in legal and technical questions.

# Engineering Supersedes Tradition

**The engineer, having learned that action is best based upon the fullest and most accurate determination of facts possible, is said to be the type now needed by the world. This is the seventh article in The Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"**

By
C. F. HIRSHFELD
Associate A.I.E.E.

Detroit (Mich.)
Edison Company

MEN whose procedures have been based mostly on precedent and tradition have for many generations had the affairs of the world in their hands. We now discover that the views and methods developed by these men are inadequate in that they do not measure up to present requirements. While this condition was being reached a new group has developed which within recent years has altered greatly many of the things having to do with human life. I refer naturally to the engineers. I use the term engineer in a much broader sense than is frequently given it. To me a real engineer is a scientifically trained business man, but the scientific training is of a variety which leads him to *apply* the results obtained by scientists rather than to expand the fields of science.

This new specimen, the engineer, represents a new type of thought. He has learned that action is best based upon the fullest and most accurate determination of facts possible at the time and under the given conditions. He endeavors to hold himself clear of the influence of preconceived ideas, traditions, precedents, rules-of-thumb.

I am not able to prove that the engineer has been appointed by God to lead the world out of the situation into which it has slowly but surely brought itself. However, in studying the history of the human race, I have noticed that individuals and groups possessing particular aptitudes and/or trainings seem to appear at just about the time the world needs what they are equipped to furnish. If this be a fact, one might be justified in assuming that the recent rapid and widespread appearance and development of the engineer indicates that he is the type now needed to carry on human development or social development or culture or whatever else you choose to call it.

I am convinced of one thing: At the present minute the world is as much in need of individuals trained and willing to discover facts and to lead where such facts indicate, as it is of anything else. I am convinced also that, by training and habit of mind, the engineer is better able to undertake such a job than is any one other single group. By this I do not mean that I believe the engineer is capable of determining unaided all of the complex variety of facts that must be uncovered if we are to alter existing conditions greatly; I assume that he will have to call to his aid others skilled in special fields; but I believe he is best fitted to assemble and direct skilled fact-finding personnel and to intepret and apply the results of its work.

I am convinced also of another thing: No such radical change in the method of handling human affairs can occur overnight. Even those changes which appear to us as revolutionary in character, upon study, prove to be evolutionary. If we have now arrived at that place in our development at which we recognize the desirability of resting action on a factual basis, we are not going to jump from here to there in the twinkling of an eye. On the contrary, we are going to go our plodding way, experimenting, arguing, discussing, and more or less applying and accomplishing, until years or generations hence our successors will be controlling the affairs of humanity by this more rational method.

---

# A Self Stabilizing D-C. Welding Generator

By
K. L. HANSEN
Associate A.I.E.E.

K. L. Hansen Engg. Co., Milwaukee, Wis.

**This new machine needs no external reactor, but employs a special field winding to compensate for resistance fluctuations in the welding circuit; it is completely self-contained and is self-excited. Provision is made for obtaining fine adjustments of current by simply shifting the brushes.**

RAPID EXPANSION of arc welding in recent years has served in an ever increasing degree to focus attention upon the design and operating characteristics of arc welding generating equipments. Up until a few years ago the d-c. arc welding circuit invariably constituted a welding *system* rather than a welding *generator*. This applies even to the variable-voltage individual-operator sets as well as to the constant-potential multiple-operator equipments. Generally speaking, the so-called arc welding generator does not possess all of the characteristics required for arc welding and to compensate for this, external auxiliary devices of one kind or another are resorted to. The generator described in this article is designed to have inherently all of the characteristics required for arc welding without the assistance of any external auxiliary apparatus whatever, and therefore is in every respect an *arc welding generator*.

## RESISTANCE CHARACTERISTICS OF ARC WELDING CIRCUIT

It is well known that the negative resistance characteristic of the arc makes it inherently unstable when operating from a constant potential circuit. To overcome this instability, the circuit must have a drooping volt-ampere characteristic; that is, the voltage must decrease with increasing current. Therefore individual-operator welding generators are designed to have a drooping volt-ampere curve. It is well known also, however, that when welding with a mild steel electrode, either bare or lightly flux-coated, the arc voltage drops to zero at more or less regular intervals whenever a drop of molten metal goes across the arc.

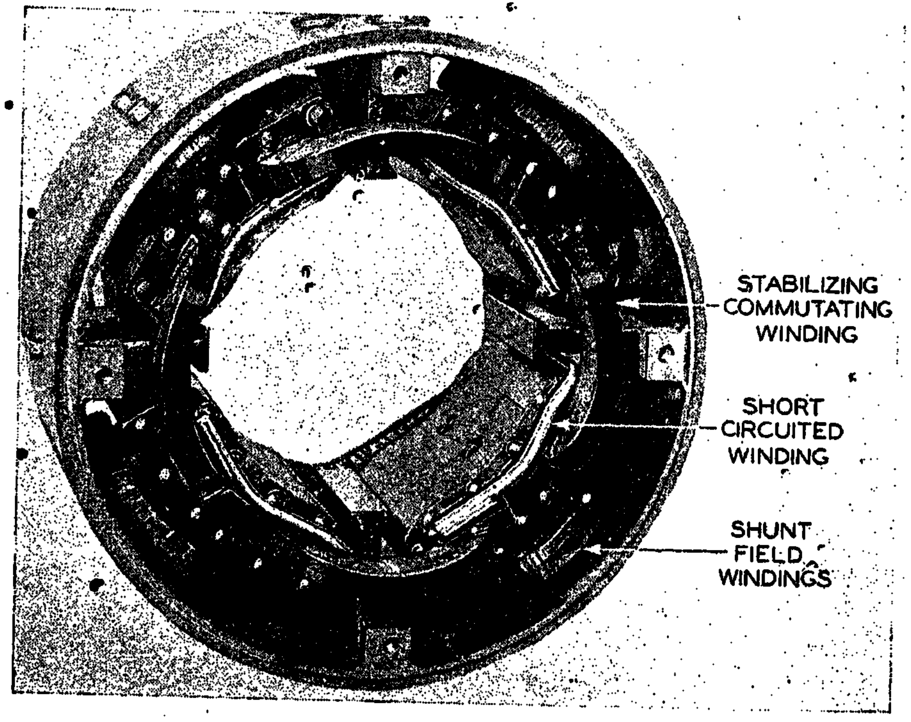

Fig. 1. Complete stator of self-stabilized arc welding generator with all field windings in place

The time during which the arc remains short-circuited is quite short, being of the order of from 0.01 to 0.02 sec. Average time intervals between drops are approximately from four to five times the length of time on short circuit. The resistance of the metallic arc, therefore, varies rapidly between zero and a value which will make the potential drop across the arc at normal welding current equal to the normal arc voltage.

Variations in arc resistance resulting from metal transfer across the arc are much wider and much more rapid than those caused by the arc's inherent negative resistance characteristic. Because of the predominating character of these resistance fluctuations, the circuit to which an arc welding generator is delivering energy consists, from the standpoint of generating equipment, of a resistance which is periodically being short-circuited at a rate of from ten to twenty times per second.

## TREND IN DESIGN

Importance of minimizing the momentary current fluctuations, or transients as they frequently are called, is discerned clearly in the most recent modifications in the design of arc welding generating equipments. Publications which have appeared lately on the subject indicate that considerable effort has been directed toward that end. For example, in some makes of apparatus the well known reactor which has been used extensively to smooth out the current fluctuations has been modified to utilize impulses from it to speed up the flux changes in the generator field. One such modifica-

---

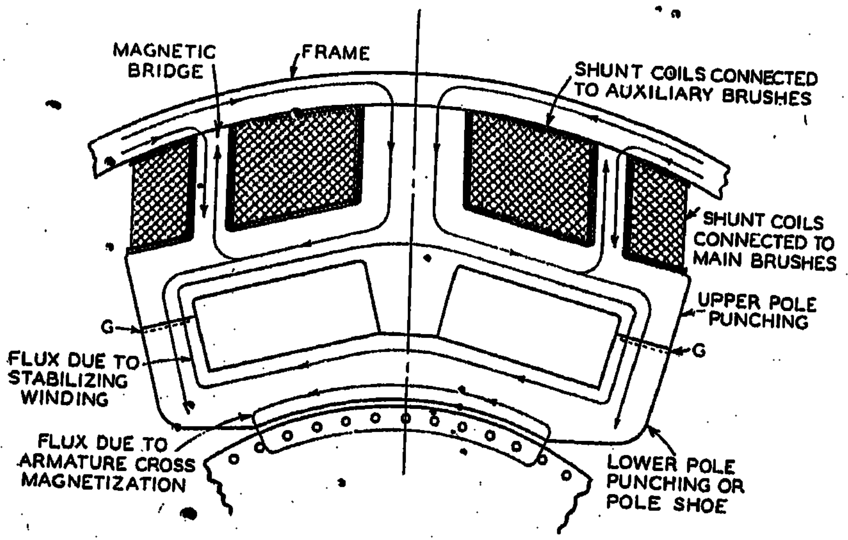
Based upon "Recent Developments in Design of Arc Welding Generators" (No. 32-43) presented at the A.I.E.E. winter convention, New York, Jan. 25-29, 1932.

tion known as the "flexactor" has been described by Blankenbuehler (A.I.E.E. TRANS., V. 50, June 1931, p. 656-61) and another, the "transformer reactor," by Bergman (A.I.E.E. TRANS., V. 50, June 1931, p. 678-80). Apparently these modifications of the reactor have resulted in marked improvement in operation.

The desirability of eliminating the external stabilizer is recognized quite generally; however, to accomplish this requires that some means for stabilizing the arc be provided within the generator itself. On the basis of these and other known facts, then, it probably will be conceded that an ideal welding generator is one in which:

1. The external reactor has been eliminated, provided this has been accomplished without introducing undue complications.
2. Current impulses in the main circuit are reflected into the generator field to quicken magnetic flux changes and thereby make the machine more responsive to changes in the external resistance.
3. The exciter has been eliminated without resorting to a two-pole armature and four-pole field structure.
4. All regulating rheostats and switches have been eliminated without limiting the range or adjustment of welding currents.
5. Desirable arc characteristics are obtained over the whole range.

A generator which in the author's opinion fulfils these requirements now will be described briefly.



MAGNETIC BRIDGE

G
G
FLUX DUE TO STABILIZING WINDING
FLUX DUE TO ARMATURE CROSS MAGNETIZATION
LOWER POLE PUNCHING OR POLE SHOE

Fig. 2. Cross-section of generator main pole with the two shunt windings in place

Attainment of the first two objects enumerated has been made possible by a novel design of the commutating winding, shunt windings, and main poles; and by adding a special winding consisting of one turn short-circuited upon itself. The armature is similar to a standard d-c. armature, except that it is wound with a relatively large number of turns and has a correspondingly large number of commutator bars. In arc welding generators this is desirable for several reasons as will be shown in the following discussion.

With a large number of turns on the armature, it is recognized generally that a comparatively great change in the terminal voltage requires only a small change in the field flux; this makes the machine responsive to external resistance variations. With a high number of commutator bars, the volts per bar is low, which becomes a marked advantage in connection with the scheme of excitation to be described later.

In Fig. 1 is shown the field ring of the generator with all poles and field windings in place. It may be noticed that instead of being wound in the usual way on the commutating poles, the commutating coils have been extended to, and completely imbedded within, the main pole flanges. The commutating winding thus extended and surrounded by laminations functions as both a stabilizing and a commutating winding. The desired stabilizing effect thus is obtained without adding any windings to those ordinarily employed in commutating pole machines.

Method of assembling the pole flanges around the stabilizing winding can be observed readily from Fig. 1, assisted perhaps by reference to Fig. 2. As may be noticed, the pole is made up of two parts, the upper part being bolted to the generator frame. The stabilizing coil, which has been wound and formed to the proper curvature on a press, then is laid into slots in the upper part of the poles. Finally, the pole shoe is put in place and bolted to the upper part. This part of the pole serves as a common magnetic path for the stabilizing flux and the flux due to armature cross-magnetization.

From Fig. 2 can be noted also that the generator has two shunt coils separated by a magnetic bridge. The function of this arrangement and of the short-circuited winding is described in the discussion of an equivalent diagram of the electric and magnetic circuits. It may be pointed out here, however, that the axial length of the back of the pole—that is, the part bolted to the frame—is considerably shorter than the axial length of that part of the pole constituting the magnetic circuit of the stabilizing winding.

## EXCITATION AND CURRENT CONTROL

The well known reentrant volt-ampere curve of the shunt generator is not at all suitable for arc welding, since it is essential that the permanent short-circuit current be equal to or greater than the welding current.

D
MMF OF STABILIZING WINDING

Fig. 3. M.m.f. diagram for two poles of generator. Note relative positions of main and auxiliary brushes

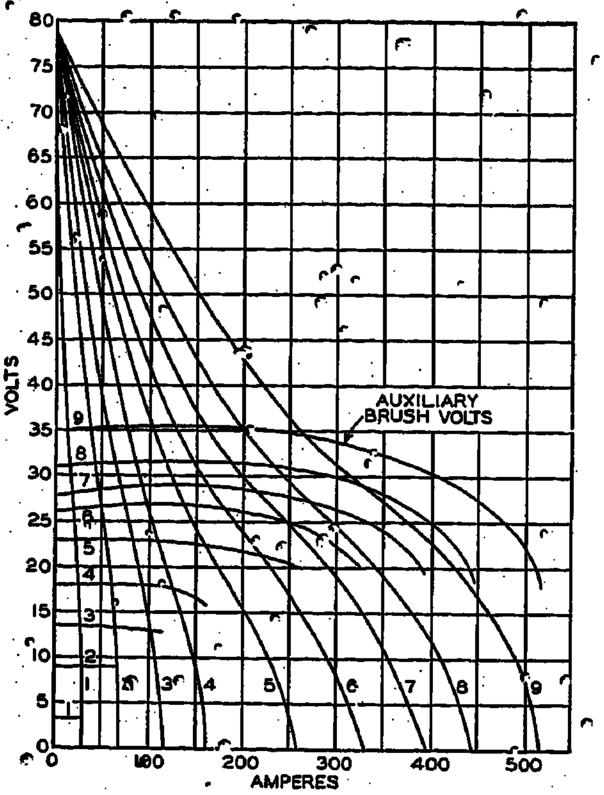

**Fig. 4. Volt-ampere characteristics and auxiliary brush voltage for different brush positions**

Main and auxiliary brushes are shifted together without altering their relative positions

For that reason some source of excitation must be available even on short circuit when the voltage across the main brushes is zero. Reference to Fig. 3 will show how this is accomplished.

In addition to the main brushes, the machine is equipped with two sets of auxiliary brushes spaced from 50 to 60 elec. deg. ahead of the main brushes. These excitation brushes have an unusually high contact resistance and can handle without commutation difficulties a much higher voltage per bar than ever is reached in these generators (which, as already pointed out, is unusually low). Line *A* represents the no-load field form, part of the negative portion of which is taken in by the auxiliary brushes. The voltage across the auxiliary brushes on open circuit therefore is proportional to the rectangle *BCDE*. The question that arises now is, "what will be the situation under some load conditions, for example, on short circuit?" First assume that magnetic saturation is negligible on short circuit so that fluxes are proportional to m.m.f's. Voltage in the shunt coil excited from the main brushes falls to zero on short circuit and the m.m.f. of this field is reduced to line *F*. In addition, a direct demagnetizing force from the armature reduces the m.m.f. on the field still further to line *H*. The remaining m.m.f's. are those due to the armature cross-magnetization and the stabilizing winding.

Distribution of flux in the air gap under the main poles is not affected directly by the m.m.f. of the stabilizing winding, but is affected indirectly by this m.m.f. when the pole shoe becomes saturated. Neglecting that for the moment, the flux distribution is the resultant of the net m.m.f. of the field and the m.m.f. of armature cross-magnetization. This is shown in Fig. 3 as a dotted line; the area included between this line and the base line, and lying above the base line, represents positive flux; similarly, the area below the base line represents negative flux. Thus upon short circuit, considerable positive flux still exists between the auxiliary brushes, whereas the net positive flux between the main brushes has been reduced greatly.

When the main and auxiliary brushes are shifted forward simultaneously, two phenomena become pronounced: The armature demagnetization is increased, and the voltage on the auxiliary brushes is decreased, both of which tend to reduce the current. Thus a wide variation in current can be obtained with a relatively small shift of the brushes. Actually the brushes are shifted by means of a micrometer screw arrangement, making possible minute gradations of welding current.

A set of volt-ampere curves of a 300-ampere welder is shown in Fig. 4. For the larger current values the voltage on the auxiliary brushes remains practically constant up to about normal current for that setting, and then drops off somewhat at short circuit. However, even at short circuit the auxiliary brush voltage is high enough to maintain a sufficiently large value of short-circuit current. For lower current values, the auxiliary brush voltage tends to remain substantially constant even at short circuit.

When the pole shoe, which as mentioned previously, carries the flux of both the stabilizing winding and the armature cross-magnetization, becomes saturated, the air-gap distribution and consequently the compounding of the auxiliary brushes are affected thereby. Saturation of the pole shoe can be modified, however, by introducing air gaps in the path of the stabilizing flux, as for example at points *G* in Fig. 2.

## MOMENTARY CURRENT FLUCTUATION AND ARC RECOVERY

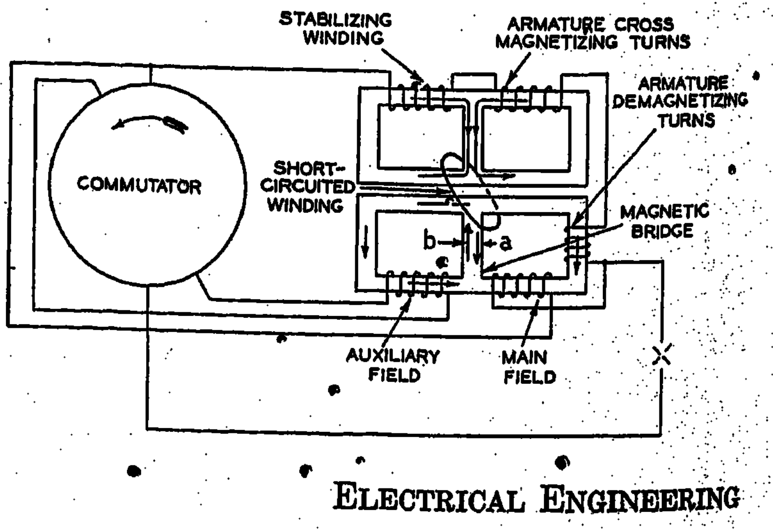
**Fig. 6. "Equivalent" diagram of generator and welding circuit (right)**



conditions, an *equivalent* circuit diagram of the generator is shown in Fig. 6. It should be understood that this is not an actual diagram of the circuit (compare with Fig. 5) the separation of the armature cross-magnetizing and demagnetizing turns, for example, being for convenience only.

The stabilizing winding and armature cross-magnetizing turns are shown opposing each other with a common magnetic circuit, the pole shoe, between them. The armature demagnetizing turns are shown opposed to the two shunt fields and it should be observed that the flux within these turns is responsible for the voltage at the main brushes. The magnetic circuit, encircled by the auxiliary field winding, is the main pole body, and the magnetic bridge is interposed between the auxiliary field and main field windings. In the absence of saturation no mutual induction exists between the stabilizing and the two shunt windings, so they have been shown as having separate magnetic circuits.

The two shunt coils are excited in the same direction; however, unless the main pole body is saturated, but little flux passes through the magnetic bridge on open circuit and this in the direction indicated by arrow *a*. On short circuit the m.m.f of the main field winding disappears and an opposing m.m.f. of armature demagnetization appears. Now a large amount of flux passes across the bridge, but in the direction of arrow *b*; that is, instead of reducing the flux in the main pole body (which flux interlinks with the auxiliary field winding) almost all of it is diverted through the bridge. The result is that the energy stored in the auxiliary field changes but very little as the terminal voltage varies. Advantages of eliminating the necessity for changing the energy stored in this field when the external resistance varies, are obvious.

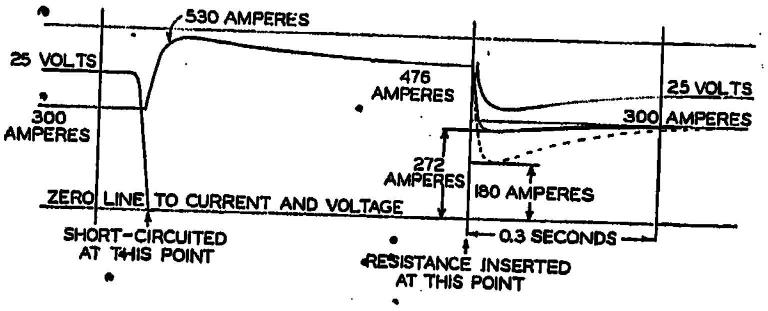


**Fig. 7. Replotted oscillogram of test made according to U.S. Navy specifications on 300-ampere welding generator**

Dotted line represents current drop and recovery time permitted by Navy specifications

To make still faster the response of the machine to variations in the external resistance, the short-circuited winding is made to form a link between the stabilizing and the field windings. When the current in the stabilizing winding increases rapidly, a current will flow in the short-circuited winding which assists in reducing the field flux. When the current in the stabilizing winding is decreasing rapidly, the transient current in the short-circuited winding assists in building up the main flux. With this method of utilizing impulses from the arc circuit to speed up flux changes in the field, no high potentials are generated in any circuit at any time to subject the insulation to undue strain.

### Some Tests on the New Machine

The A.I.E.E. test of a welding generator for momentary current fluctuation and arc recovery is as follows: Adjust generator on resistance load to obtain normal current at 25 volts; short-circuit one-half the resistance and allow current to settle; then suddenly open the short circuit and reinsert the resistance in the circuit. The current momentarily drops below normal and the *time of recovery* is the time required for the current to return to within 5 per cent of its original value.

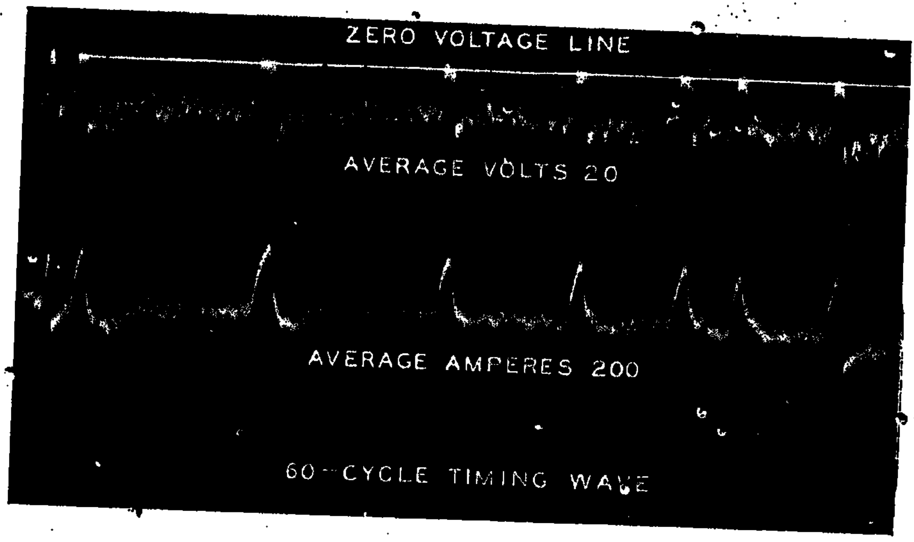

**Fig. 8. Oscillogram record made during an actual welding operation with the new generator**

This test is of little value because the resistance variation is not wide enough to cause any noticeable depression of current below normal upon reinserting the resistance circuit; that is, not if the machine is worthy of being termed an *arc welding generator*. United States Navy specifications, however, call for the same test for arc recovery with the exception that all of the resistance must be short-circuited and then reinserted. This test means something.

A replotted oscillograph record of a test made according to the latter specifications at normal load on a 300-ampere welder of the type just described is shown in Fig. 7. The dotted line indicates the drop in current and the time of recovery permitted by the Navy specifications. It may be noticed that whereas the Navy permits the current to drop to 180 amperes, for this machine it actually drops to only 272 amperes. In Fig. 8 is shown an oscillograph record made when welding with a bare, mild steel electrode, and with an average welding current of 200 amperes and an average of 20 volts across the arc.

# A Corona Tube Voltage Regulator

A corona tube may be used to regulate the output of a full-wave rectifier and therefore to control the excitation of a generator to give constant voltage. Performance curves for a five-kva generator whose voltage is controlled by such a regulator indicate advantages over other types.

By
**H. W. DODGE** Non-member — New Jersey Bell Tel. Co., Newark, N. J.
**C. H. WILLIS** Member A.I.E.E. — Princeton University, Princeton, N. J.

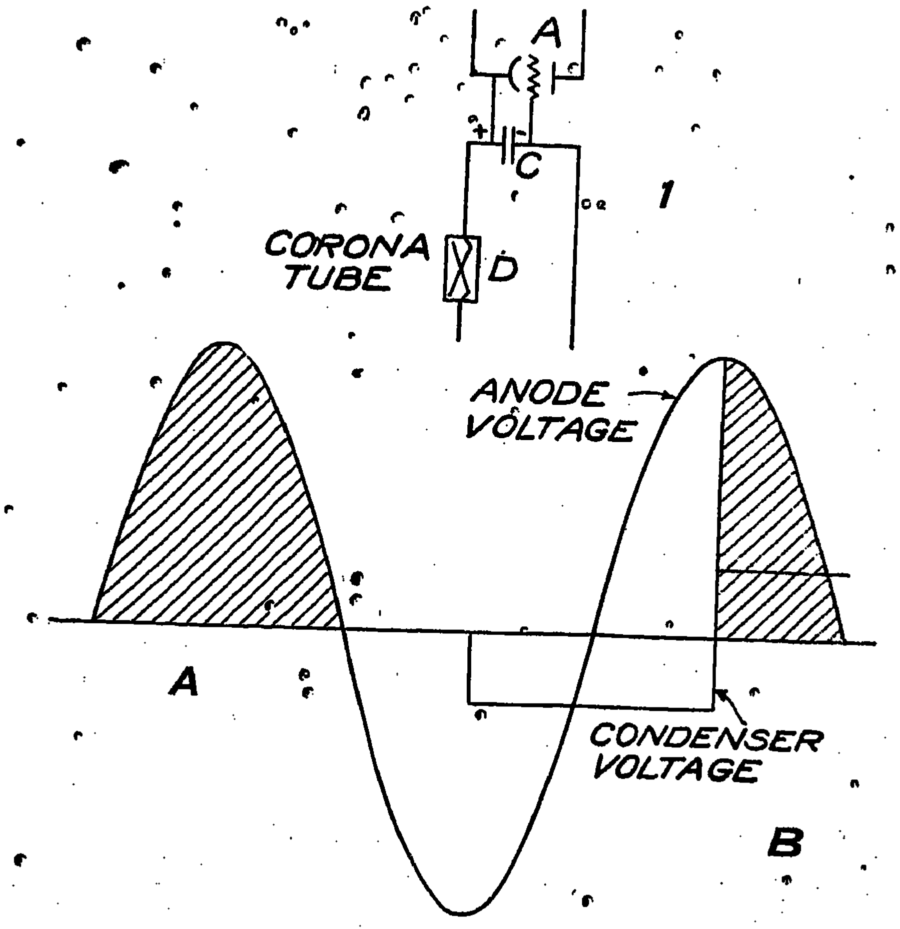

Fig. 1. Voltage wave and simplified circuit of corona tube and rectifying tube

A VOLTAGE REGULATOR consists essentially of a constant element; an element which varies with the voltage and which is balanced against the constant element; and an arrangement for using this balance to control the excitation of the machine whose voltage is to be regulated.

In the familiar vibrating contact regulator the modulus of elasticity of a spring is the constant element. Acting against the spring is the pull of a solenoid which is dependent upon the voltage. The forces due to the solenoid and the spring act on a plunger which operates a contact by which resistance is put into or taken out of the generator field circuit, thereby regulating the generator voltage.

The most serious disadvantages of the vibrating contact regulator are:

1. Wear and sticking of the contacts.
2. Periodic fluctuations of the voltage with opening and closing of the contacts.
3. Slow response to fluctuations of the voltage, due chiefly to the time lag of the field circuits of the exciter and the generator.

Recently a number of new types of regulators has been devised. Almost any phenomenon which varies with voltage may be made the basis of a voltage regulator, such as the saturation of an iron core reactor, the resistance of a conductor heated by the voltage, or the internal resistance of a thermionic tube whose filament is heated by the voltage. The regulator described below employs the critical voltage of a corona tube as the basic phenomenon.

The corona discharge tube employed consists of two symmetrical electrodes sealed into a glass tube containing an inert gas at a suitable pressure. Due to the fact that the tube contains a definite quantity of gas constrained to a fixed volume, the mean free path of an ion and therefore the corona voltage are practically independent of the temperature. Since ionization builds up very quickly at a voltage above the critical value, the breakdown voltage is also independent of the frequency, for frequencies within the commercial range. With the electrodes surrounded by an inert gas such as argon there is negligible disintegration of the electrodes during discharge; the breakdown voltage of the tube is constant and the life very long.

These characteristics of the corona discharge tube make its critical voltage suitable for the constant element in a regulator. The fact that it regulates to a constant peak voltage rather than a constant effective voltage is not a serious disadvantage, for the variation of wave form with load is not appreciable and there will therefore be a constant form factor.

In order to control the excitation of a generator we may use the charge passing through the corona tube above the corona voltage to bias the grid of a rectifying tube and thereby regulate the amount of rectified current which will be supplied to the generator field. Any type of rectifying tube may be used. However the high efficiency and large amplification factor of a gaseous tube, such as the thyratron, make this type of tube very desirable.

In order to explain the principle of operation, the simplified circuit shown in Fig. 1 will be considered first, and the voltage applied to the anode and cathode of the rectifying tube will be assumed to be in phase with the

---

From "A Corona Tube Voltage Regulator" (No. 31-112) presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1931.

voltage in the corona tube circuit. The thyratron tube *A* has a negative grid characteristic, and it therefore normally conducts current into the field of the generator during the half wave when the anode voltage is positive, as indicated by the shaded positive half cycle. During the half wave when the anode voltage is negative the condenser *C* will be charged as indicated by the polarity marks, provided the circuit is connected with the proper polarity and provided the voltage rises above the critical value for the corona tube. During the first part of the next positive half wave the thyratron cannot conduct current because the grid is negative. However the grid bias will be reversed by the corona tube at the peak of the voltage wave, and the thyratron will conduct current during the latter half of the positive voltage wave as shown by the cross-hatched area. In this way the average value of the rectified current will be reduced to one-half the full half wave or maximum value when the voltage is above the breakdown value for the corona tube.

If a voltage is impressed on the corona tube which lags in phase behind the rectifier voltage, the average current may be reduced to less than 50 per cent of its maximum value because the grid bias will then be reversed after the peak of the voltage wave. When the corona tube is supplied from a voltage 60 degrees behind the rectifier voltage as in a three-phase machine, the corona tube will reduce the average current to 7 per cent of the maximum value.

The circuit as described above will vary the excitation by definite steps and will give fluctuations in the excitation just as are produced by opening and closing the contacts of a vibrating regulator. However if a leak is placed across the grid biasing condenser of a value such that the time constant *CR* of this condenser and leak is about equal to the period of one-half wave, then the grid condenser voltage may be reduced by leakage to a value where the thyratron will start. The time it will take to reduce the grid voltage to the starting value will depend on the initial charge of the grid condenser, and this is determined by the excess of the voltage above the critical voltage of the corona tube. Therefore the time of starting for the thyratron rectifier in any half wave will be delayed by an amount which is determined by the excess of the voltage above the breakdown voltage of the corona tube. This is indicated in Fig. 2. A small rise in total voltage above the critical value will serve to reduce the rectified current to about 7 per cent of its maximum value. However this change is continuous.

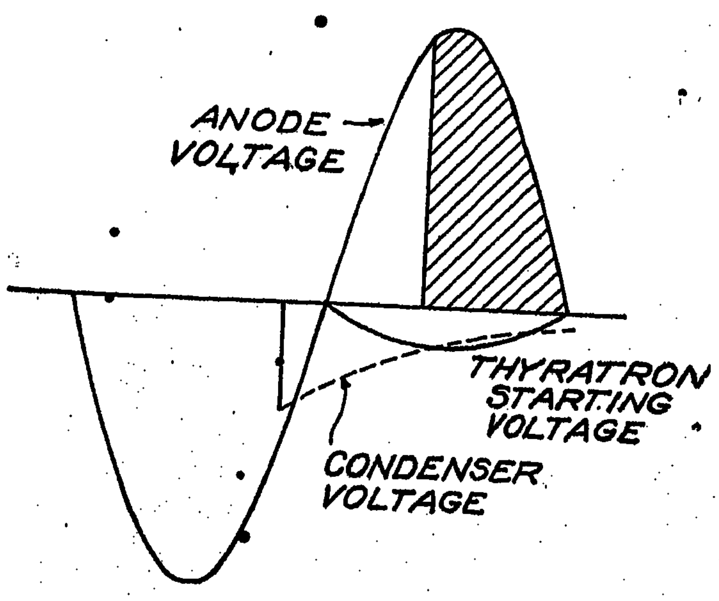

**Fig. 2. Voltage waves with leak across grid biasing condenser**

The circuit used for controlling a full-wave rectifier by means of a corona tube is shown in Fig. 3. It was found quite difficult to make corona tubes so symmetrical that they would break down at the same voltage on the positive and negative half waves. However by adding the condenser $C_4$ shown in Fig. 3 it is possible to eliminate any unidirectional components of current and cause the corona tube to have the same positive and negative critical values.

In the regulator used for the results given below, the thyratrons were too small to rectify the entire field current and their output was used for the field of an exciter.

In this case a further difficulty arose in the time

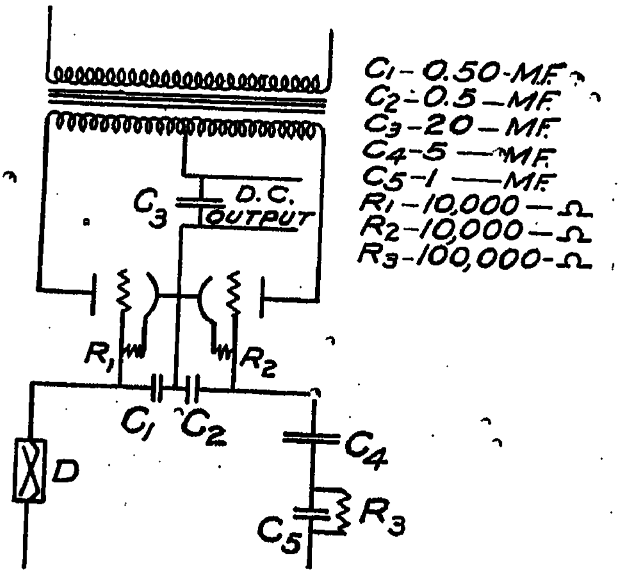

**Fig. 3. Corona tube voltage regulator circuit for full-wave rectification**

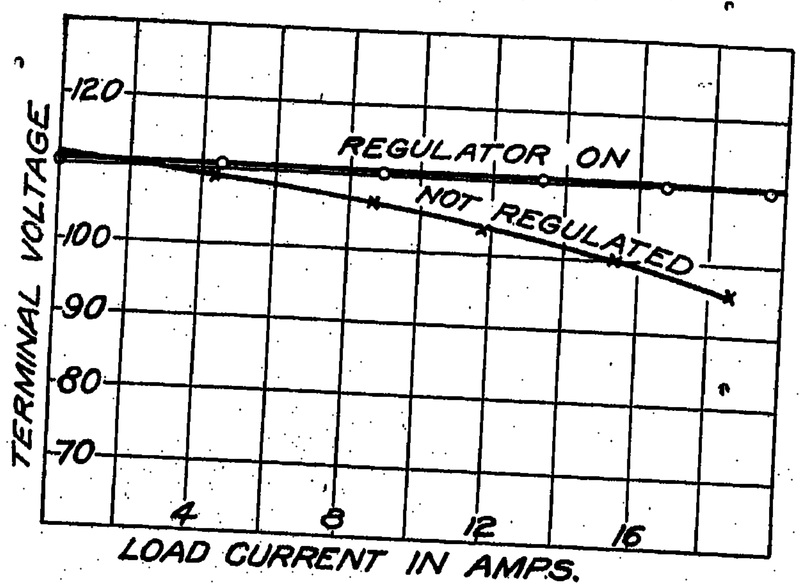

**Fig. 4. Voltage regulation with variation in generator load**

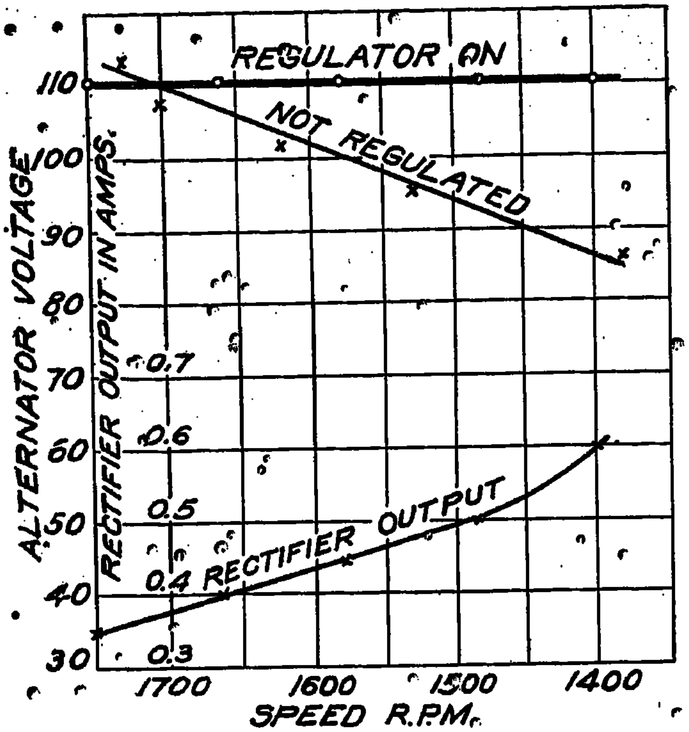

Fig. 5. Voltage regulation and rectifier output with variation in exciter speed

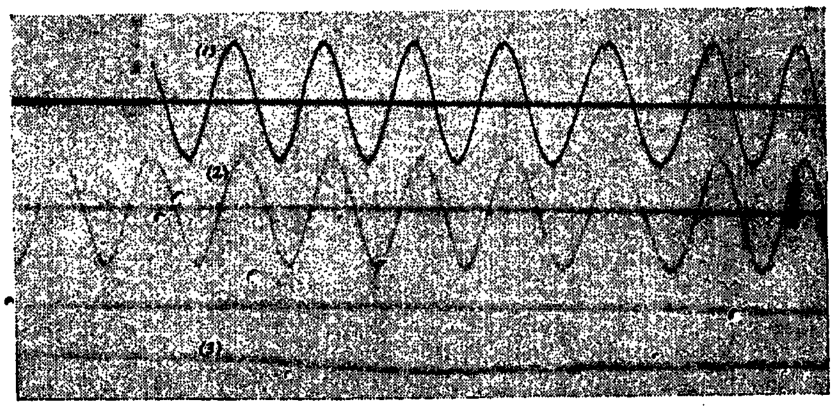

Fig. 6. Oscillograms of (1) load current, (2), alternator voltage, and (3) regulator output when suddenly applying full load to generator

lag of the exciter and alternator fields in responding to a change in the rectifier output. This caused oscillations of the generator voltage of about the period of the time constant of the field circuit. It was found possible, to suppress these oscillations by introducing into the corona tube circuit a transient of about the same period as the oscillations. This transient is introduced by a condenser with a leak as shown at $C_5$ and $R_3$ of Fig. 4, such that $C_5R_3$, the time constant, is about equal to $L/R$, the time constant of the slowest field circuit.

The constants of the regulator circuit as used are shown in Fig. 3. The critical voltage of a corona tube with given dimensions and gas pressure may be predicted from the data giving the corona voltage of the gas to be used. The tube as used contained argon at a pressure of two centimeters of mercury. The electrodes were parallel wires 0.25 mm. in diameter and separated 1 cm. The critical voltage of this tube was approximately 350 volts peak value.

The results shown in the curves of Figs. 4 and 5 were taken on a five-kva. three-phase motor-driven alternator excited from a 110-volt motor-driven exciter. In the curves of Fig. 4 the effects of load variation are shown while Fig. 5 shows the regulation when the speed of the driving motor is varied. The oscillograms in Fig. 6 shows the transient conditions when full load was suddenly thrown on the generator.

This type of regulator would employ the same methods of compounding and line drop compensation now in use. It is believed that the simplicity, compactness, high sensitivity, and quick response of this corona tube regulator offer advantages over the other types.

# Photoelectric Recorder Has High Sensitivity

**A new recorder has been developed which employs for the measuring and recording operations separate elements coupled together by a combined optical and photoelectric system. Tests show that the new instrument is as accurate, sensitive, and responsive as a good indicating instrument.**

By
**C. W. La PIERRE**
Associate A.I.E.E.

General Elec. Co.
Schenectady, N.Y.

AS SOON AS an instrument is developed which is capable of *indicating* the value of any quantity, attempts usually follow to make its function partly automatic by having it *record* its readings. Ordinary direct-acting recorders are the heavier and higher-torque counterparts of corresponding indicating instruments; although such recorders have some highly desirable characteristics, such as rapid response and the furnishing of a continuous record, their sensitivity cannot be made to approach that of indicating instruments. In other cases it is desirable to utilize the instrument for controlling the indicated quantity. These additional requirements involve the performance of mechanical work but in many cases the necessary additional energy is not available from either the instrument or the mea-

---

Based upon "The Photoelectric Recorder" (No. 32-15) presented at the A.I.E.E. winter convention, New York, Jan. 25-29, 1932.

sured circuit. Thus in the past the application of indicating instruments to recording and control operations has not been possible beyond certain limits.

The photoelectric recorder described in this article combines all of the advantages of direct-acting recorders with those of the most sensitive indicating instruments. This is accomplished by providing a separately excited recording element to do the actual work of making the record. A sensitive indicating instrument controls the position of the recording element so that the record obtained represents the readings of this basic instrument. The loss in the sensitive basic instrument is the only power required from the measured circuit.

A combined optical and photoelectric system is utilized to link together the basic and recording elements of this new instrument. The basic element itself rotates a galvanometer mirror through an angle corresponding to its reading, and can be made even more sensitive than the usual indicating instruments of the pointer type. Furthermore, the recording element may possess as much torque as required and be made as heavy and sturdy as desired without affecting the basic element or measured circuit in any way. As a result, the photoelectric recorder possesses all of the desirable characteristics of direct-acting recorders, and at the same time is capable of a sensitivity and a rapidity of response equal to that of the highest sensitivity indicating instruments.

An interior view of this new recorder is shown in Fig. 1. The instrument is completely self-contained and requires only an auxiliary power source of 115 volts, 60 cycles; it is available for either portable or switchboard use. Internal parts of the recorder may be grouped into five units: (1) the basic indicating instrument or galvanometer; (2) the optical system; (3) the recording element; (4) the chart carriage; and (5) the power unit.

The basic instrument is the only *measuring* device within the recorder. It may be similar to almost any ordinary indicating instrument or galvanometer element, but the particular basic instrument used determines the sensitivity and rapidity of response of the resulting recorder.

A schematic diagram of the optical system may be seen in Fig. 2. In general this arrangement comprises a group of reflectors so arranged that an angular displacement between the recording and basic elements will cause a shift in light distribution between the photoelectric tubes, which in turn reacts on the recording element to reduce the displacement to zero. Thus the optical system acts to maintain the recording and basic elements in the same angular position at all times. How this is accomplished may be determined by inspection of Fig. 2. The important reflectors are: the basic element mirror *A*, the curved reflector *B*, recording element mirror *C*, and finally, the dividing reflector *D*.

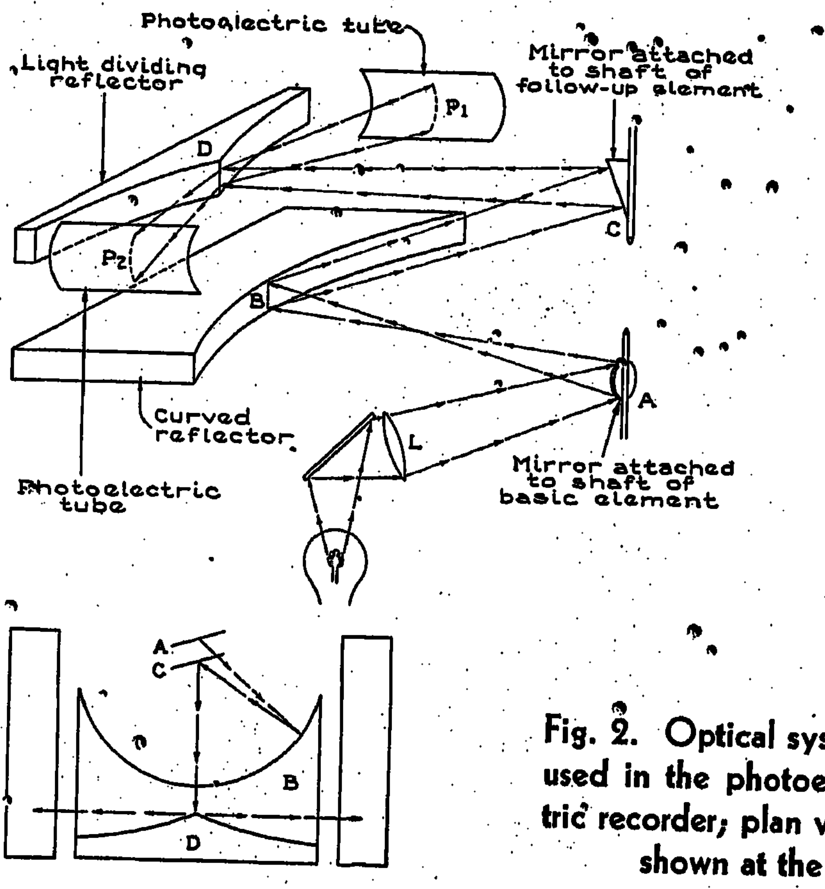

**Fig. 2. Optical system used in the photoelectric recorder; plan view shown at the left**

The recording and basic elements usually are mounted on the same axis, or very nearly so, although this is not necessary for successful operation of the instrument. The lamp and condensing lens converge a beam of light upon the basic element mirror *A* from which it is reflected to the curved mirror *B*. The point where the light strikes mirror *B* will depend upon the angular position or "reading" of the basic element, but regardless of where it strikes *B* it is reflected to mirror *C* attached to the shaft of the recording element. From *C* the beam is reflected to *D* at an angle depending upon the angle of reflection from *B* and also upon the position of the recording element. When *C* and *A* are parallel, however, the light will split evenly upon the dividing edge *D*; this

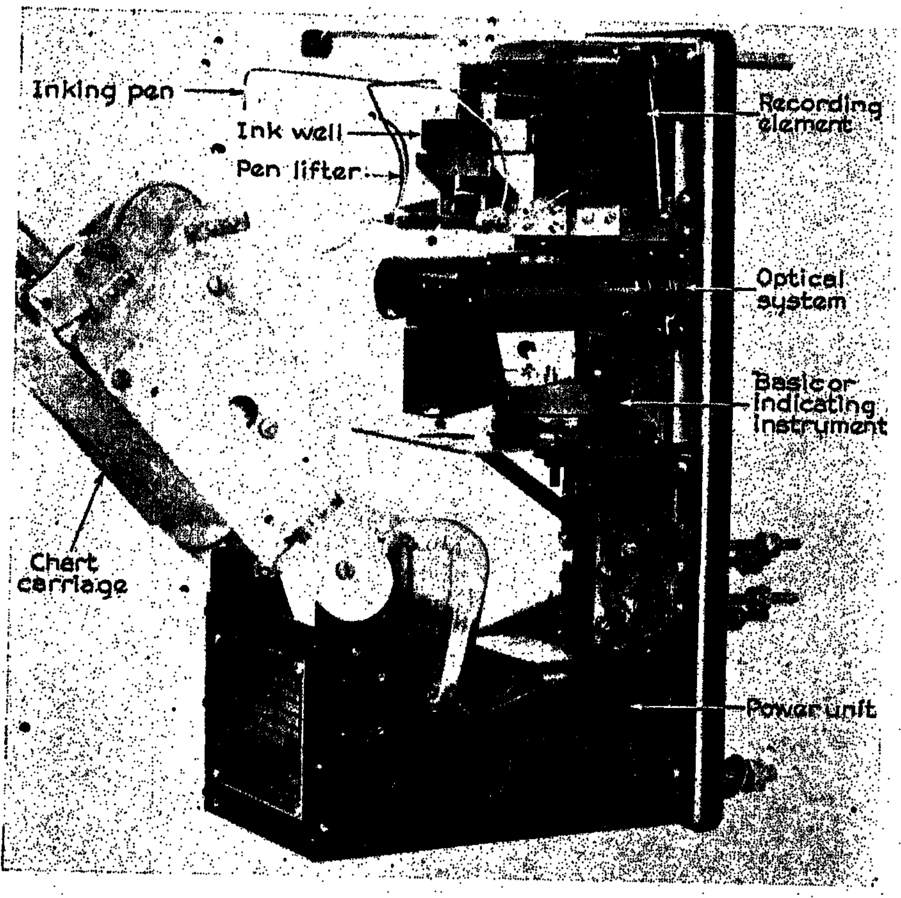

**Fig. 1. Interior view of one type of photoelectric recorder with chart carriage tilted out**

holds regardless of the actual positions of *A* and *C* so long as they are parallel to each other. If they are not in this parallel position, the light will strike to one side of the edge of *D*; more of it thus will pass into one photoelectric tube than into the other and cause the recording element to turn until *A* and *C* are parallel. Relations between the various angles of incidence and reflection are shown in the plan view shown in the lower right hand corner of Fig. 2; by slightly displacing the mirrors from their true positions, the different paths of light can be traced readily.

Power to operate the recording element is controlled by the photoelectric circuit (See Fig. 3). Of greatest importance is that part of the circuit beyond the field coils of the recording element. A portion of the d-c. voltage across the field coils is applied to the three-element pliotron tube; the plate current of this tube passes through the recording element armature connected in the filament side of the circuit to permit grounding one armature lead. Another portion of the voltage across the field coils is applied to the two vacuum type photoelectric tubes which are connected in series with their common junction connected to the grid of the pliotron.

This circuit possesses very high sensitivity to changes in the distribution of illumination between the two tubes so that the slightest unbalance of light in either direction between the tubes will throw the grid voltage to one extreme; a slight unbalance in the opposite direction will throw the grid voltage to the opposite extreme. These extreme grid voltage swings occur far too fast under normal conditions to make the circuit useful for purposes of recording. However, the response of the circuit may be made as slow as desired without sacrificing the high sensitivity and its obvious advantages. This is accomplished by inserting a capacitor and resistor in series between the grid and filament of the pliotron tube. With these added to the circuit it is necessary to alter the charge upon the capacitor before the grid voltage can change, and the time lag of this procedure may be adjusted to any degree by changing the value of the capacitance. Without the damping capacitor and resistor violent hunting would take place between the recording element and the photoelectric circuit, whereas with the damping circuit in use, all tendency to hunt or overshoot can be eliminated completely.

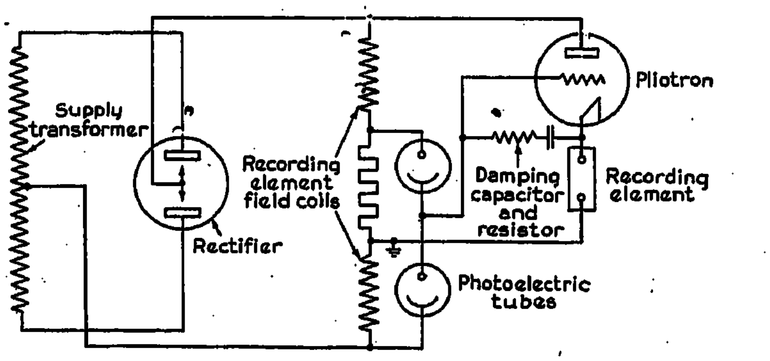

Fig. 3. Photoelectric circuit for controlling the recording element

The recording element may be any ordinary sturdy unit which will produce sufficient torque from the output of the pliotron tubes. Likewise the inking system and chart carriage may be of conventional design.

### ACCURACY

In any new instrument all possible sources of error should be investigated carefully. The mere mentioning of a possible source of error, however, should not be interpreted in any way to mean that that particular source is an important one; in fact all known factors which might affect the accuracy of the instrument are mentioned mainly for the purpose of showing how extremely small are their possible effect.

Variation in the supply voltage does not affect the accuracy of the photoelectric recorder within rather wide limits. Voltage changes are automatically compensated for by corresponding changes in the recording element current and thus produce no discernible effect upon the record. Changes in vacuum tube characteristics also are automatically compensated by the circuit in the same manner as are voltage fluctuations. Changes in lamp illumination caused by variations in the supply voltage, deterioration of the filament or blackening of the bulb, ordinarily do not produce any effect upon the recorder during the life of the lamp. Changes in illumination also may result from the reflectors becoming dusty or fogged. These variations in illumination may cause a noticeable slowing down of the operation of the instrument but do not affect its accuracy in any way.

Variations in photoelectric tube sensitivity may be cited as another possible source of error. Proper design of the optical system however has reduced the effect of such changes to a secondary and negligible order of magnitude. It has been found that errors due to this cause are limited at most to a few tenths of one per cent, and this only after a considerable period of time. Resetting the instrument on zero at occasional intervals would eliminate the possibility of even this small error. Other possible minor sources of error include vacuum tube grid currents, photo tube dark currents, and leakage currents in the grid circuit. All of these tend to react in the same manner as changes in the photoelectric tube sensitivity. The magnitude of all stray currents, however, may be reduced without difficulty to from one-tenth to one-twentieth of the actual control current, so that the effect is entirely negligible.

Upon the basis of the foregoing it may be said that a photoelectric recorder is practically self-compensating for all normal changes in supply voltage, lamp illumination, and vacuum tube and photoelectric tube characteristics. Tests made so far indicate that this recorder has a sustained accuracy over long periods in the same order of magnitude as would be expected from a high grade indicating instrument.

# The Kindling of Electric Sparkover

**Experimental evidence is presented which tends to prove that electrons and not protons or positive ions are the active carriers in the spark kindling mechanism and that Lichtenberg figures form the initial step in the process.**

By
C. E. MAGNUSSON
Fellow, A.I.E.E.
University of Washington, Seattle

ELECTRIC SPARKOVER and the kindling mechanism by which it takes place recently has become the subject of much discussion. Results of investigations already made furnish ample evidence that the process is extremely complex and that the speed of formation is in the order of $10^8$ cm. per sec. instead of $10^4$ or $10^5$ as previously thought. Many factors such as polarity, shape of electrodes, ionization, space charges, voltage gradients, air pressure, and temperature, also are known to affect the process. Although previous investigators have been able to throw some light upon certain phases of the initial or kindling stage a comprehensive explanation of the complete process still is lacking.

The investigation described in this article presents a new method of approach to the problem and the results furnish additional information concerning the kindling period, that is, the first few microseconds of the sparkover process. Apparatus used in the tests has been described previously (A.I.E.E. TRANS., Vol. 49, 1930, p. 1384). It consists essentially of a specially designed air-tight photographic plateholder (see Fig. 1) which is placed in the field of a powerful electromagnet. Voltage impulses forming the Lichtenberg figures are impressed upon two electrodes the ends of which are held in contact with the sensitized surface of the photographic plate. The apparatus is arranged so that the field of the electromagnet is at right angles to the plate the desired pressure inside being maintained by means of a vacuum pump connected as shown. To simplify the discussion and particularly any references to illustrations, the direction of the magnetic field will be designated by the letters *S* and *N*, *S* indicating that the plate-holder was placed in the field so that the south pole is in front of the printed page, and *N* indicating the reverse.

A graphical representation of the path which an electron would follow on the emulsion surface of the plate in passing from the negative to positive electrodes under combined stress of dielectric and magnetic fields is given in Fig. 2, direction of the magnetic field being assumed as *S*.

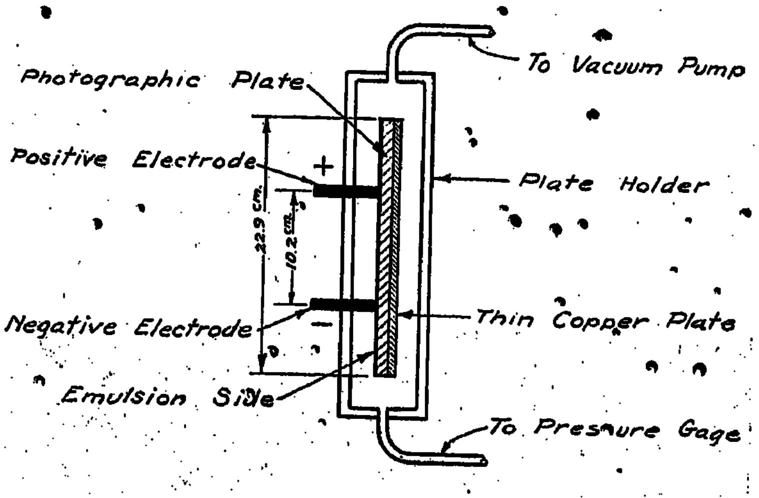

Fig. 1. Cross-section of air-tight plate-holder

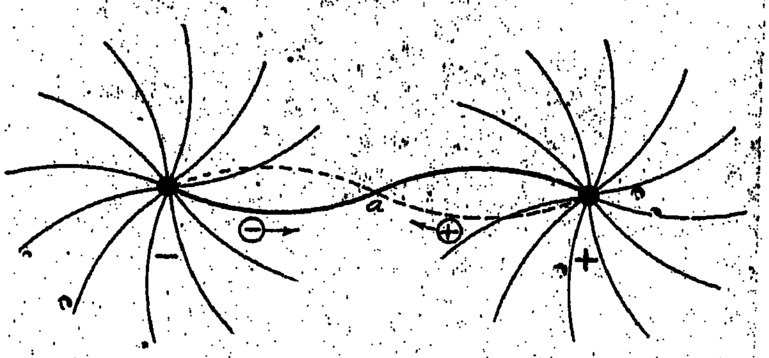

Fig. 2. Graphical representation of electron and proton paths between two electrodes under the combined stress of dielectric and magnetic fields

Consider an electron projected from the negative electrode under the given conditions and passing through the point *a* midway between the two electrodes. The electrostatic force of repulsion from the negative electrode and attraction to the positive electrode combined with the reaction from the magnetic field at right angles to the direction of motion, will cause the electron to move along a path similar to that indicated by the solid line. It is evident that under the combined action of the dielectric and magnetic fields the paths of *all electrons falling into the positive electrode* will move in paths bending in the counterclockwise direction, with reference to the positive electrode. Hence, if *electrons* be the active elements in the sparkover process the path followed by the spark should have a double inflection as illustrated by the full line in Fig. 2. On the other hand, if positive ions or *protons* be the active elements in the sparkover mechanism the path followed by the spark likewise should have a double inflection, but must be curved in the reverse direction, as indicated by the broken line in Fig. 2.

---

From "The Kindling of Electric Sparkover Based on Lichtenberg Figures," (No. 31-123) presented at the A.I.E.E. Pacific Coast convention, Lake Tahoe, Calif., Aug. 25-8, 1931.

Deflections of the sparkover path therefore can be used as a criteria in determining whether electrons or protons are the active elements in the sparkover process.

On the basis of the foregoing discussion consider the three sparkovers recorded in Fig. 3. In *b* the field direction was *S*, the same as used for the diagram in Fig. 3. The sparkover path has a double deflection exactly like that of the solid line curve in Fig. 2. In *a* and *c* the direction of the field was *N*, that is, reversed as compared to the direction in *b*; deflection of the sparkover paths in *a* and *c* also are reversed as compared to *b*. It is evident therefore that according to the argument advanced in the preceding paragraph, electrons were in each case the active elements in the kindling stage.

By reducing the air pressure within the plate-holder the bending effect of the magnetic field is increased, and deviation of the sparkover path from a straight line increases proportionately. A series of sparkover photographs accordingly were taken at air pressures ranging from atmospheric to 0.02 mm. Hg. The double inflection of the curve, in each case, followed the path that would be taken by negative charges, that is, electrons, as illustrated in Fig. 2 by the solid line.

The sweep of the nebulous positive figure, when formed at low air pressure and under the stress of the magnetic field, is revealed in Fig. 4. The double inflection of the sparkover path, arrested before complete sparkover occurred, is very marked, and is in complete accord with the analysis of the electron path (solid line) indicated in Fig. 2. There is no evidence of a counter flow of positive ions or protons in either this or any of the other photographic records.

## CONCLUSIONS

Although the number and range of experiments made on Lichtenberg figures on sparkovers formed under stress of magnetic fields are limited, the results obtained together with the many important relations previously determined seem to warrant the following observations:

1. Lichtenberg figures represent, or are formed by, elementary electric sparks. On this basis the process of formation of these figures would represent also the kindling mechanism of the simplest form of sparks.
2. Lichtenberg figures or the electric sparks producing them form the initial step in the sparkover process.
3. Sparkover develops from the tips of the positive Lichtenberg figures and tends to follow the positive and negative streamers.

# Reestablishing Excitation of a Loaded Alternator

**Operating tests on large turbine-generators indicate that following the accidental opening of the field switch of a loaded machine, service should be restored by closing this switch as soon as possible, without removing the generator from the bus.**

By
D. D. HIGGINS

E. WILD
Associate A.I.E.E.

Both of
Commonwealth Edison
Co., Chicago, Ill.

SWITCHBOARD operators in generating stations are at times suddenly confronted with troubles which call for immediate action. Such a situation results with the unexpected opening of the field switch of a loaded generator, and the operating rules of different power companies are by no means in agreement as to the proper procedure in this emergency.

In an attempt to determine exactly what happens when the field switch of a large alternator is opened and a short time later reclosed, a group of tests was conducted. The most interesting of these tests is illustrated by Fig. 2 which is a faithful reproduction of oscillograph records. These were taken on the cross-compound 60,000-kw. 60-cycle 12,000-volt unit illustrated in Fig. 1. The high pressure generator is rated at 1,800 r.p.m. and has 5.8 ohms synchronous impedance, while the low pressure generator is rated at 1,200 r.p.m. and has 1.92 ohms synchronous impedance. The external reactors between the unit and the bus are 827-kva., 3,500-ampere, and have 3 per cent reactance at 12,000 volts.

As illustrated in Fig. 2, the machine was carrying 50,000 kw. at 80 per cent power factor lagging when the switch was opened. The total load lost following the opening of this switch was 40 per cent. Root-mean-square values of armature current and voltage are shown, the field current and turbine speed being instantaneous values.

The action of both units of the machine is evident from the oscillograms. Upon opening the field switch, the generator field was short-circuited by discharge resistors and the field currents of each unit almost immediately dropped to less than half value. Then for a period of four seconds the fields gradually became demagnetized, the station bus voltage dropped, and the armatures gradually drew heavy magnetizing currents from the system. Following this and until the field switch was reclosed, transient conditions existed with both machines running considerably above synchronous speed. The speed of the high pressure turbine was very erratic and violent governor action was observed. The low pressure turbine, not having a speed regulating governor, ran at a more uniform speed. A further reason for the steadiness in the speed of the low pressure turbine can probably be found in the fact that the reheat boiler served as a stabilizer for the rapidly pulsating steam that was passing through the high pressure turbine. Since the heat in the reheat boiler was constant it momentarily would give off more reheat to a smaller amount of steam at a lower pressure, and less reheat to a larger amount at higher pressure.

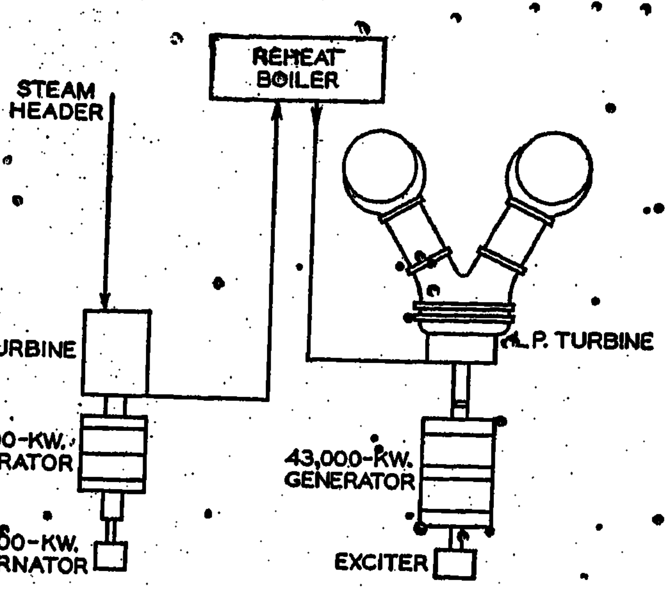

**Fig. 1. Plan of two-element 60,000-kw. turbine-generator unit No. 2 at Crawford Ave. station**

As the magnetic coupling between the field and the armature poles was removed on the opening of the field switch, the energy produced by the turbine accelerated the machine above synchronous speed. The field winding then cut lines of force and had induced in it a current which had a frequency proportional to the slip; that is, the difference between the armature speed and field speed. The general characteristics of the machine were those of an induction generator. The governor on each machine prevented it from reaching an excessive speed, and the necessary exciting current was drawn from the line.

As indicated by the oscillograms the field currents reversed each time a field pole passed over an armatures pole. The armature currents plotted as r.m.s. values are seen to have a maximum and a minimum value for each reversal of the field current. Ordinarily an induction generator would have constant armature current for a given speed. The peak values found on these tests may be explained by the fact that the field does not have a uniformly distributed winding such as would be found in the rotor of an induction machine.

Whether or not the shunt wound exciter would have

---

Based upon "Reestablishing Excitation of a Loaded Alternator in Parallel with Others" (No. 31-101) presented at the A.I.E.E. summer convention, Asheville, N. C. June 22-26, 1931.

become demagnetized if the field switch had been closed when the induced field current was a maximum in the reverse direction was not definitely determined. However, in the worst case found in these tests the low pressure field was 550 amperes in the reverse direction and passing through a discharge resistance of 0.56 ohms so that the voltage which would have been thrown across the exciter momentarily would have been 308 volts. This might have been enough to demagnetize an exciter set at 275 volts, although it is thought that the time required to weaken and reverse the exciter magnetism would be greater than the duration of the induced generator field current at its maximum negative value. Another factor preventing demagnetization of the exciter is that the field current of the high pressure unit would have to be negligible or also reversed at the same time, since the net current in the common exciter is the sum of the instantaneous field currents in the high and low pressure units.

In each case when the field switch was closed, the field current instantly started to build up in the right direction, the armature currents returned to their normal values in about 5 seconds, the station voltage recovered to almost normal in the same length of time, and in about 20 seconds the station voltage had completely recovered. In each case the machine recovered synchronous speed in less than 2 seconds.

As a result of these tests and of a number of questionnaires sent to operating companies and manufacturers, fairly definite conclusions may be drawn. It is felt that when for any cause the field switch of a loaded alternator is opened unexpectedly, the usual practise of taking the unit off the system, re-exciting and resynchronizing it, is unnecessary and that considerable time in restoring normal operations without severe disturbance to the system is obtained by closing the field switch as soon as possible. The generator need not be removed from the bus at any time except in rather remote cases. It is recognized that different types of generators behave differently when the excitation is cut off, and that the older units having low resistance field windings and operating with 125-volt excitation are more erratic than later machines employing 250-volt excitation. It may be safely stated, however, that if the unit is carrying less than three-quarters load, there is no danger in reclosing the field switch. If the unit is carrying more than three-quarters load it will be prudent to lower the governor before reclosing the field switch. Also, if the bus voltage has dropped to 60 per cent of normal it is considered advisable to cut off the generator so as not to increase the tendency of other generators dropping out of step. However, such a reduction in voltage due to an open field is unlikely on large systems.

Owing to its reactance, it is impossible for the rotor field to increase to full strength immediately; it also follows that due to a weaker magnetic coupling it is impossible for the rotor to change speed instantly, and there can be no shock such as occurs when a machine is paralleled out of phase. To insure proper polarity when closing the field switch, the exciter, if self-excited, should always be operated above the knee of its saturation curve. The belief that while the switch is open excessive current which would prove injurious might be induced in the field winding was not borne out by the observed values of current.

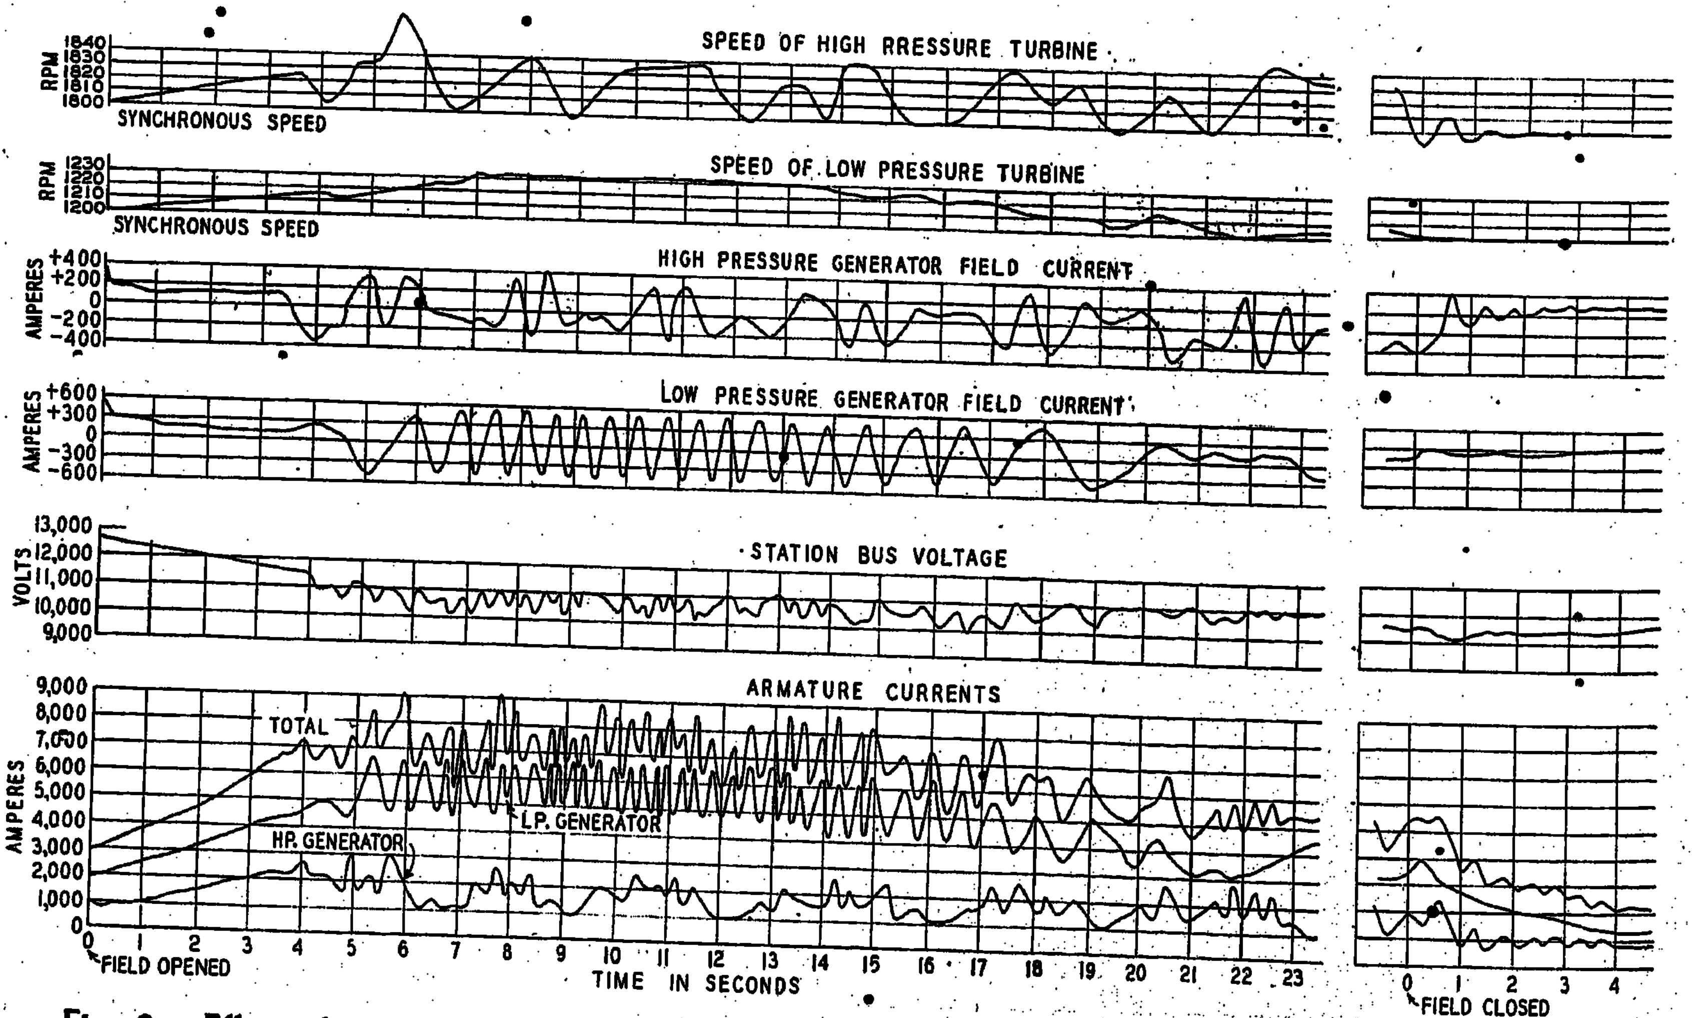

Fig. 2. Effect of opening and later reclosing the field switch of unit No. 2 at Crawford Ave. station. The machine was carrying 50,000 kw. at 80 per cent power factor when field was opened

# Hinged Wooden Arms Used on Osage-Rivermines Line

**Extra insulation was obtained on this important link of the Union Electric Light and Power Company transmission system by the use of wood crossarms. By hinging the arms to the steel tower structures, arm and tower stresses were reduced materially; consequently tower weights and line costs were lowered accordingly. Details of these and other major features of this unusual line are given in this article.**

HINGED WOOD CROSSARMS have been adopted for the 119.5-mile power transmission line which connects from the Osage hydroelectric development to the Rivermines substation of the Union Electric Light and Power Company (Mo.). Wood arms were selected because service requirements demanded better performance than that usually obtained with double circuit lines supported by all steel structures. These arms were hinged to the steel structures because of cost considerations: with such construction the forces applied to both arms and towers when conductor wires break are much lower than with rigid arm towers; consequently the cost of such towers is from 15 to 20 per cent lower than for rigid arm towers. Tests showed that with these arms and 11 insulator units, the line insulation is equivalent to that obtained with from 17 to 23 units on steel arms. Design of the arm involved the development of a suitable clamp for the tension member, details of which are given later.

The Osage hydroelectric development[1,2] (for numbered references see bibliography) is situated near the geographic center of the State of Missouri and about 140 miles west of the load center of the Union Electric Light and Power Company. Initial development includes six 33,500-hp. generating units. Two 132-kv. transmission lines were built to deliver the plant output to the existing transmission system which in a general way follows the Mississippi River from Keokuk, Iowa, on the north to the lead mining district near Rivermines, Missouri, on the south. One of the new lines is a single-circuit wood-frame line 135.5 miles long reaching from Osage to the Page Avenue substation in the outskirts of St. Louis; the other is the steel tower line with hinged wood crossarms, which is the subject of this article.

Important data of the Osage-Rivermines line are summarized in Table I. Each of the two circuits is designed to handle the output of two hydroelectric generators each rated 23,888 kva. at 0.9 power factor, and 60 deg. cent. (27,500 kva. at unity power factor, and 80 deg. cent.) through a single bank of transformers. Later, the power station may be equipped with a main bus, whereupon either circuit may be called upon to deliver the full air-blast bank rating of 60,000 kva.

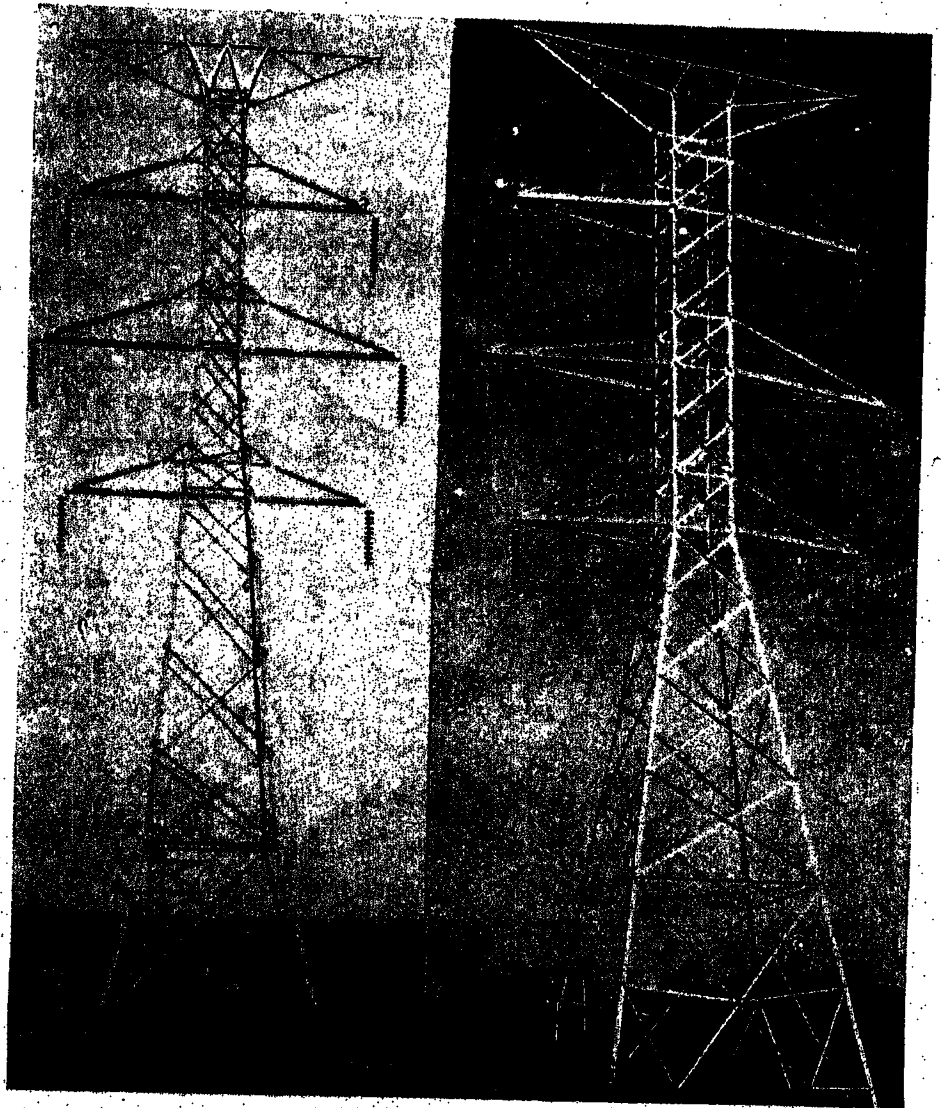

Fig. 1. Typical tower with hinged wood arms (left) and (right) tower with rigid wood arms as used at angles in the line and at certain long spans

---

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

Energy transmitted annually will vary between 50 and 250 million kw-hr. per circuit.

To make the best use of the hydroelectric development, it will be operated as a peak cut-off plant replacing equivalent steam capacity in St. Louis. Such a procedure can be justified only on the basis of equal reliability. At a distance of 120 miles in a country with Missouri's record for sleet and lightning, this is an exacting requirement but was accepted as the basic specification for the Osage-Rivermines line.

A double-circuit steel tower line had been considered as being most suitable from a cost standpoint; yet it was felt that the service required fewer outages, particularly those involving both circuits, than the records of this type of construction would indicate as probable for a 120-mile line. More insulation seemed to be the principal need and it was suggested that some of the advantages of wood pole line construction might be realized by using wood crossarms.[3,4,5,6]

A preliminary study of the application of wood insulation to the crossarm assembly showed that it would involve a marked increase in cost as compared with steel unless some compensating measures were adopted. Aside from an arbitrary reduction in the factor of safety, which was considered with some misgivings, the only course available was to reduce the forces applied to the arms and tower when conductor wires break. The problem of reducing the forces from broken wires has received quite a bit of attention from transmission engineers and has resulted in the development of a number of slip clamps as well as in the hinged crossarm. (The metal hinged arm is not new.[7] Its operation was demonstrated publicly in this country in 1927 and the Public Service Company of Northern Illinois has 3 miles of line with hinged steel arms built in 1928.)

For the foregoing reasons, therefore, and because of its adaptability to the wood insulation idea, hinged arm construction finally was adopted. The arms are hinged at the tower end on an axis inclined away from the tower at the top by an angle of 20 deg. This inclination of the axis causes the swinging movement to be restrained by the weight of the arm and by any vertical load it may be carrying, so that normally the arm acts in the same way as though it were rigid. If a wire should break, the arm swings away from the broken span reducing both torsional and overturning moments.

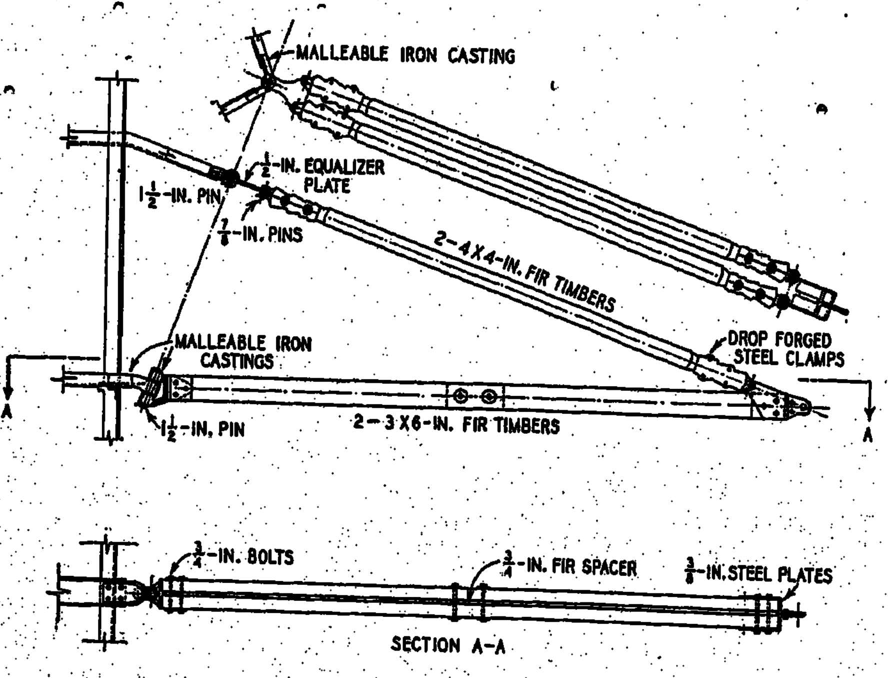

Fig. 2. Details of hinged wood arm

## DESIGN OF HINGED WOOD ARMS

Construction of the arm is quite simple, consisting as it does of a pair of tension members and a compression member pinned together at the outer end. (See Fig. 2.) Tension members are in duplicate while the compression member is built up from two similar timbers bolted together; this is to minimize the effect of any shattering from lightning. With either tension member or either half of the compression element put out of commission, the assembly still is strong enough to carry any normal loads likely to occur.

Untreated Douglas fir was chosen as the material for the arms because it offered certain advantages in durability, strength, availability, economy, and ease of working. Some of the more important mechanical properties of the grade of wood selected are approximately as follows:

| | |
|---|---|
| Tensile strength | 7,000 lb. per sq. in. |
| Shear strength parallel to grain | 900 lb. per sq. in. |
| Compressive strength perpendicular to grain | 500 lb. per sq. in. |
| Compressive strength parallel to grain | 3,500 lb. per sq. in. |

No extraordinary difficulties were encountered in the design of the compression member. The tension member, however, offered a rather serious problem because of

**Table I—Pertinent Features of Osage-Rivermines Line**

**Length.** 119.5 miles (631,014 ft.) all on steel towers.

**Circuits.** 2—132-kv., 3-phase, 60-cycle.

**Conductors.** 6—250,000-cir. mil, 19-strand, copper.

**Ground wires.** 2—7/16-in., 7-strand, Siemens-Martin steel, galvanized.

**Standard tower height.** To peak 91 ft.; to bottom conductor 42 ft.-4 in.

**Standard tower extensions.** Single or multiple leg extensions, 4 ft. and 8 ft. Body extensions, 16 ft. Footing extensions, 2 ft.

**Standard tower wire spacings.** HORIZONTAL BETWEEN CIRCUITS: ground wires, 29 ft.; conductors, top 29 ft., middle 35 ft., bottom, 29 ft. VERTICAL: between conductors 14 ft.; between ground wires and top conductors 20 ft.-8 in.

**Length of span.** Average 827 ft., normal 700 ft., maximum 2,208 ft.

**Standard tower loading.** Equivalent span for vertical loading, 1,500 ft. Equivalent span for transverse loading 1,100 ft. Wire loads ½ in. radial ice and wind pressure of 8 lb. per sq. in.; any two wires broken; factor of safety against failure 1.5.

**Wire tensions (normal span).** CONDUCTOR: 2,450 lb. at no ice, no wind, 60 deg. fahr.; 5,500 lb. at ½ in. ice, 8 lb. per sq. in. wind pressure, 0 deg. fahr. GROUND WIRE: 1,300 lb. at no ice, no wind, 60 deg. fahr.; 4,250 lb. at ½ in. ice, 8 lb. per sq. in. wind pressure, 0 deg. fahr.

**Standard tower weight.** Tower proper, 7,600 lb.; hinged arms 2,100 lb. (timbers, 1,000 and metal parts, 1,100); footings 1,200 lb.; total, 10,900 lb.

**Standard conductor arms.** Hinged on axis tilted 20 deg. from vertical. Duplicate tension members, 4x4-in. fir with forged steel clamps. Compression member, 2—3x6-in. fir timbers, blocked and bolted together. Wood insulation varies from 6.3 to 10.3 ft.

**Insulation.** On wood arms, 11-unit suspension strings, 13-unit strain strings. On steel arms, 16-unit strings. No arcing horns on initial installation.

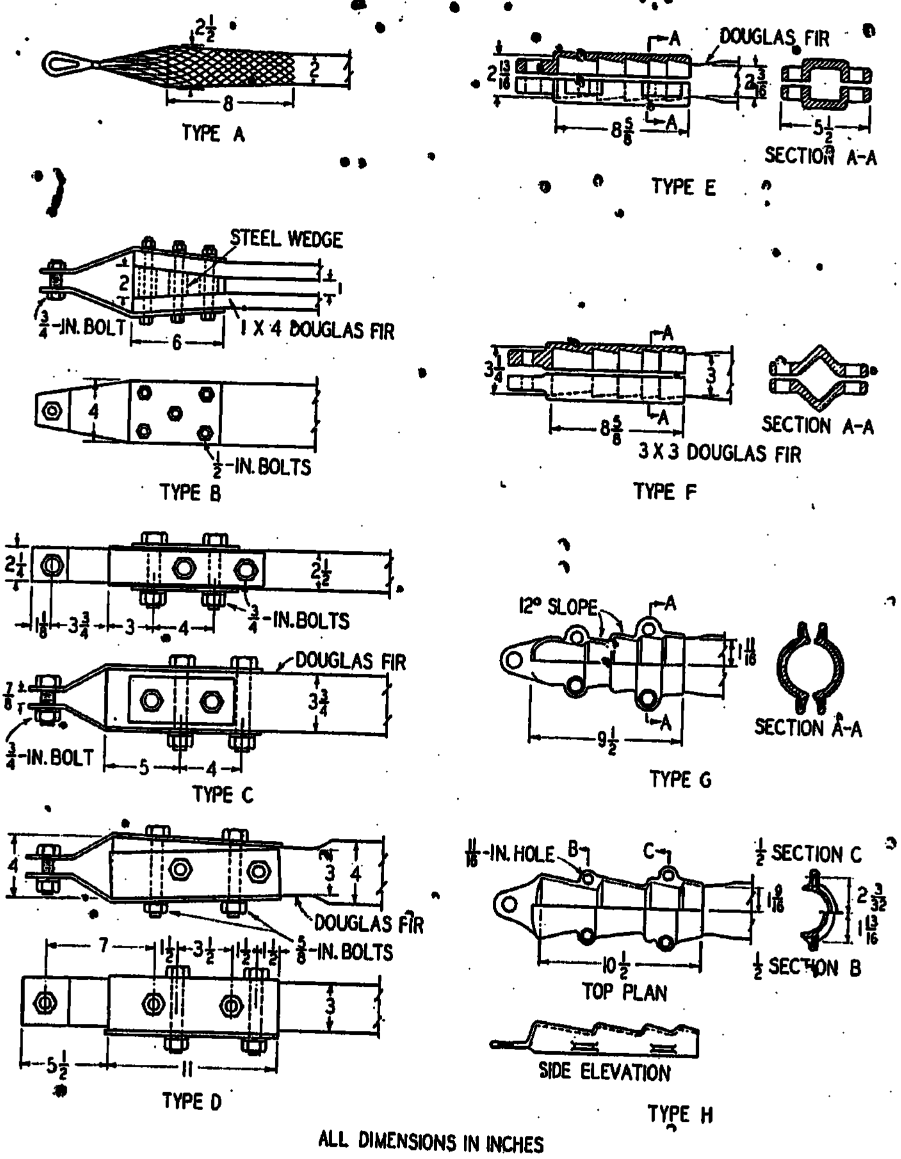

**Fig. 3. General types of wood strain insulator fittings tested; type H finally was selected**

See Figs. 5 and 6 for general theory and design of wedge type clamps applying to all of the above fittings

the difficulty of making an attachment to a wood member so as to develop any great portion of the load which the wood is capable of sustaining in tension. This is because wood is comparatively weak in shear parallel to the grain and in compression perpendicular to the grain.

With these facts in mind, an extensive series of tests was conducted to develop a fitting suitable for the tension member. Some of the more general types of fittings tested are shown in Fig. 3. Type *H* fitting finally was adopted, it having been found to possess the following advantages:

1. Tendency of the wood to decay should be comparatively small as the clamp encloses almost the entire member, at the same time providing ventilation, and as there are no bolts through the wood.
2. Probability of the wood splitting due either to lightning strokes or to seasoning is eliminated largely by the clamping action of the fitting.
3. The metal is in close contact with the wood at all times; hence, the device should be free from leakage current troubles.
4. Strength of the attachment is not affected materially by a small amount of shrinkage in the wood because the taper permits a corresponding slippage which in turn readjusts the clamp. Experience has indicated, however, that if the wood is put up green and allowed to season in place, the bolts should be tightened after the wood has taken its initial shrinkage.
5. Drop-forged hot galvanized steel clamps of this type with copper bearing surfaces provide the required strength and length of life, with a high degree of reliability.

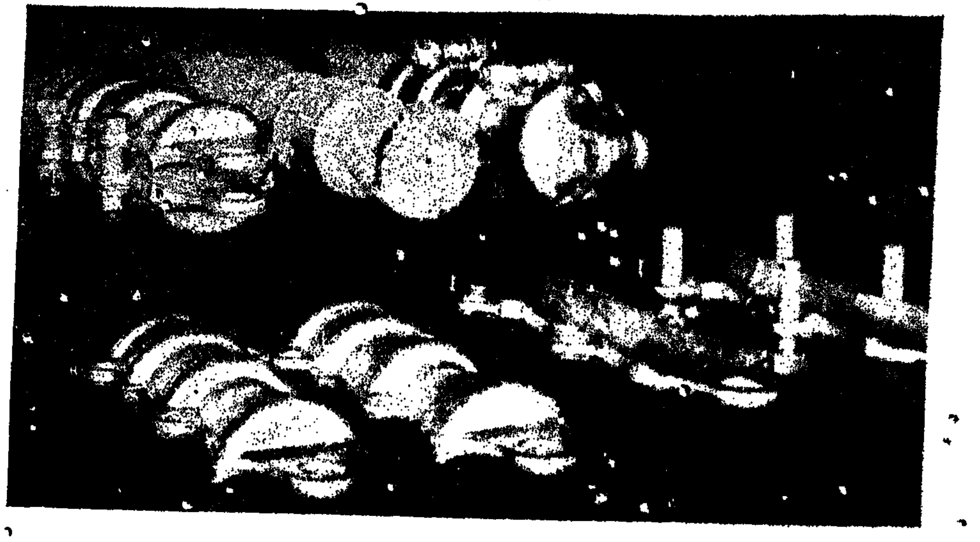

**Fig. 4. Tension members of hinged wood arms showing method of applying clamps**

Two of the fittings are clamped onto each end of a 4x4-in. timber to make up the complete tension member (the ends of the timber of course being turned down to the proper shape). (Fig. 4.) In the wedge-like operation of this fitting the tensile load is translated into compression and shear stresses, the ratio between the two being controlled by the angles of the sloping surfaces and their coefficients of friction (see Figs. 5 and 6). By making the steps near the end of the stick successively smaller in diameter, each step tends to work on a different set of fibers with the result that the load is well distributed throughout the timber.

Ultimate breaking strength of the member with this type of fitting varies from about 35,000 lb. for a clamp having galvanized wedge surfaces, to about 50,000 lb. for a clamp having rough wedge surfaces. This difference is due to the fact that, for a given pull, the corresponding compression load on the wood varies inversely as the tangent of the sum of the friction angle and the angle of inclination of the wedge surfaces (see Figs. 5 and 6).

The compression member consists of two 3x6-in. timbers bolted together with ½-in spacers at the midpoint or third points, depending upon the length of the arm. (Figs. 2 and 7.) The end fittings were designed to bring as much of the compression load as possible directly upon the ends of the timbers rather than on the bolts the primary function of which is to hold the assembly together rather than transmit load. The fitting at the outer end is made up from forged steel plates which in addition to applying the load to the compression element, provide places of attachment for the tension members and the suspension insulators. At the tower end the compression timbers are seated in a malleable iron casting which forms the rotating part of the hinge.

Compression and tension elements were assembled individually in the factory; these were pinned together in the field, then hoisted up the tower as a complete arm and attached by inserting the two hinge pins. This operation proved to be quite simple as did the stringing of conductors, the latter operation being carried out in quite the same manner as on rigid arm construction.

During the rather extensive tests carried out in connection with the design of these arms, certain important details appeared as being fundamental to the success of an undertaking such as this. These are listed in the hope that they may prove helpful in any similar project in the future; they are briefly:

1. Rigid purchase specifications should be set up and repeated inspection made of each piece of timber during process of manufacture.

2. Proper attention must be given to the method of drying, whether done in kilns under special specifications or by other means.

3. If any form of treatment be used, care must be taken that the treatment does not lower the electrical resistance of the wood unnecessarily nor weaken it mechanically due to the high temperature sometimes employed.

4. Clamps and fittings attached to the timber must contain adequate provision for shrinkage across the grain and should be fitted accurately so as to distribute the stresses properly.

5. Thin sections in timbers exposed to the weather should not be used because of the unavoidable checking which becomes more serious with such sections, and the greater rate of depreciation due to the increase in exposed area.

6. Careful design can reduce the difficulties due to splitting by lightning when attention is given to the location of or possible reduction in the number of bolts through the timber. At points where electric current is likely to leave the metal and pass into the wood, the stress can be distributed somewhat by slightly flaring the metal away from the wood, rather than concentrating such stress upon a single line at sharp edges.

7. Normal continuous working stresses should be low. In designs providing for heavy ice loading this will be obtained automatically when ample strength is provided for the ice load; also in designs which provide duplication of parts to guard against the loss of such members due to lightning, similar low stresses will be obtained for normal loading.

In a relative evaluation of the above items, the first and the last probably are of greatest importance.

In this day of almost universal treatment of timbers in permanent outdoor structures, it may be surprising to some that the wood arms used in this line were not treated in any way. Treatment with creosote oil admittedly lengthens the serviceable life of wood and probably cuts down the amount of checking to a certain extent; but it had two important disadvantages in this application: it cuts down the lightning flashover voltage, definitely if slightly; and due to the lubricating qualities of the oil, it upsets the balance of design in the friction clamp on the tension member. Furthermore, as stated previously, unless extreme care is taken, there is a possibility of reducing the mechanical strength of some types of wood by the temperatures attained in treating.

It having been decided for these reasons to use untreated wood, the choice quite naturally fell to Douglas fir as mentioned previously, the highest commercial grade of which (dense superstructural) was selected. As seasoned timber of this grade is not available in any great quantity, for this job all of it was specially cut from green logs. This meant that most of the shrinkage took place after the arms were on the towers. This was anticipated and a general tightening of all bolts accordingly was scheduled for the end of the first summer season. Checking was aggravated to some extent by exposure to the intense summer heat without a preliminary seasoning.

The principal risk assumed by the substitution of wood for steel in a crossarm is the chance of shattering from lightning. The exterior of the tension members used in the electrical tests (described later) was quite badly splintered by the repeated flashovers; it is probable that the damage from real lightning would have been much worse. An attempt has been made to minimize these effects, however, by proper design of the metal fittings and provision is also made for attaching arcing horns if they should prove advisable; but the main reliance is placed in the overhead ground wires, in the duplication of the tension members, and in the two part construction of the compression element of the arm.

## INSULATION TESTS ON THE WOOD ARMS

As a check on the increase in insulation due to the wood arms, part of a tower was set up in the Trafford high voltage laboratory and the minimum surge to flash over a string of eleven 5.75x10-in. insulator units on each arm was determined. The measurements with the equivalent insulation in number of similar insulator units on steel arms were:

| | | |
|---|---|---|
| Top arm | 1,350 kv. (crest) | 17 units |
| Middle arm | 1,720 kv. (crest) | 22-23 units |
| Bottom arm | 1,550 kv. (crest) | 20 units |

Surges used for the tests rose to maximum value in 1.5 microsec. and fell to half voltage in 60 microsec. Flashovers for minimum surges had a time lag of about 40 microsec.

The arc from the top conductor jumped to the wood tension member of the middle arm, and followed this member to the tower; arcs from the middle and bottom conductors flashed up the insulator strings and to the tower, sometimes by way of the tension members and

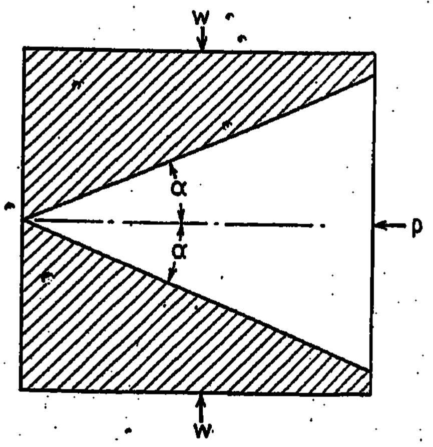

**Fig. 5. Friction clamp theory for all fittings shown in Fig. 3**

$w$ = Force exerted by resisting body
$\alpha$ = Angle of inclination of the sides of the wedge
$\phi$ = Angle of friction
$p$ = Force required to push the wedge

$$p = 2\,w \tan(\alpha + \phi) \qquad (1)$$

Similarly, the force required to withdraw the wedge is given by:

$$-p = 2\,w \tan(\alpha - \phi) \qquad (2)$$

From eq. 1 may be seen that for a given value of $p$, load $w$ decreases when tan $(\alpha + \phi)$ increases. In cases where it is desirable to keep $w$ as small as possible and it is not feasible to increase angle $\alpha$, the desired result may be obtained by employing an abrasive on the bearing surface of the wedge, thus increasing angle $\phi$.

Wedge will not keep itself in position if $\alpha$ is greater than $\phi$. This fact is worthy of consideration where the wedge is subjected to varying loads and is made of a material whose maximum allowable stress depends greatly upon the duration of the stress. In applications of this nature, $\alpha$ should be greater than $\phi$ in order that the wedge be only lightly stressed except during times of heavy loading.

sometimes by way of the compression members. Apparently enough variation existed in the resistance of the timbers to offset occasionally their difference in length.

To check the efficiency of the configuration from an insulation standpoint, measurements were made with varying insulator string lengths, crossarm lengths, and with and without adjacent crossarms. Principal criticism which developed from these experiments was to the effect that quite an appreciable gain in insulation for the top conductor could have been realized if the space between the top and middle arms had been increased by a foot or more.

Insulation of the line with eleven insulator units on wood crossarms is considerably higher than that of the substation equipment at the terminals. Therefore to assist the lightning arresters in protecting the substation apparatus from the hazard of lightning surges coming in from the line, the terminal stations are equipped with fused gaps. Owing to the difference in the equipment at the two ends of the line, the power station gaps are set at 40 in. and the receiving station gaps at 37 in.

## EFFECT OF WOOD ARM CONSTRUCTION ON TOWER DESIGN

Standard suspension towers with hinged wood arms do not appear greatly different from conventional towers (see Fig. 1) although the 20-ft. base and 4-ft. cage section used in this line are somewhat smaller than would be expected for towers 91-ft. in height. Ground wire supports are unusually prominent because of the location of the two ground wires, one being placed directly over the top conductor of each circuit with a vertical separation of 21 ft. With this arrangement, the ground wires should be well situated to intercept direct lightning strokes at midspan and divert them to the tower without side flashes to the conductor.[8] The increased moments due to this ground wire arrangement made it advisable to carry the batter of the legs up to the middle arm.

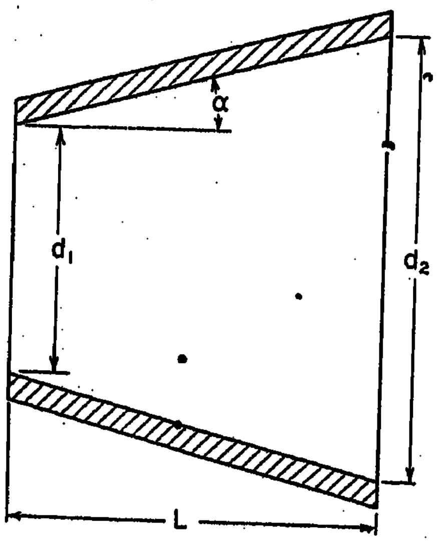

Fig. 6. Friction clamp design for all fittings of Fig. 3

$\alpha$ = Angle of inclination of wedge
$\phi_1$ = Friction angle, wood on friction surface of clamp
$\phi_2$ = Friction angle, wood on wood
$S_t$ = Ultimate unit tensile strength of wood
$S_c$ = Maximum unit compressive strength of wood, perpendicular to wedge surface
$S_s$ = Maximum unit shear strength of wood parallel to the grain

For a balanced design

$p$ = Tensile strength = compressive strength = shear strength, or

$p$ = (Cross section at front end of clamp) $(S_t)$
= $(S_c)(\text{Cos }\alpha)$(surface area of wedges) $\tan(\alpha + \phi_1)$
= Shear area of base of wedge $S_s$ + (Compressive load perpendicular to shear plane) $\tan \phi_2$

Practical considerations as to the size of the wood member to be employed might make a balanced design undesirable

A comparison between the tower design used in hinged arm construction and that which would have been required for a rigid arm line may be of some interest. It is quite apparent that towers for use with hinged arms involved the setting up of load assumptions different in some respects from those used in conventional rigid arm design. To show what these differences were and how they affected the tower design, a comparison has been developed between the hinged arm tower actually used on the Osage-Rivermines line and a tower with rigid wood arms otherwise structurally and electrically equivalent. This comparison is shown in Table II. Load assumptions used in this comparison represent unit stresses in the structures up to the elastic limit of the material beyond which it is assumed that tower failure would occur.

Vertical and lateral loads are the same for both types of construction, but in the case of broken wires the movement of the hinged arms will change the point of application of some of the loads. This introduces an unbalance in these loads which is not encountered in rigid arm design. However, the principal difference in loading rests in the magnitude and location of the longitudinal forces resulting from broken wires.

In rigid arm towers the longitudinal load generally adopted as a design basis is of the type indicated in Table II. For hinged arms the loads had to be based upon existing knowledge of hinged arm operation which was not very extensive. Lack of experience in this respect is reflected in the three more or less overlapping load assumptions (see Table II). With the accumulation of test data and operating experience, however, it is probable that a single longitudinal load assumption will be developed as in the case of rigid arm towers.

Effect of the hinged arm when wires break is to cause (1) a shift in the application of the longitudinal load to a point nearer the center of the tower, and (2) a reduction in the magnitude of this load to one-half its original value (except for the effect of impact at the end of the arm's swing which was assumed to build up to the original tension for an instant only). In case 3, where the impact forces of a breaking wire are superposed upon the forces resulting from a previously broken wire, the factor of safety was reduced as the result of a discussion as to whether or not case 3 was justified at all. These combined loadings were not applied lower than the first panel of the tower below the bottom crossarm because it was considered that the impact stresses would not extend beyond this point, but would be absorbed in the bolted connections above. Case 3 was found to be controlling in that part of the tower to which it was applied.

Weight distribution for the tower actually adopted for hinged arm service on this line is shown in Table I. Total weight of the tower (10,900 lb.) is approximately

2,000 lb. less than the estimated weight of an equivalent tower with rigid wood arms. As a result the cost of the hinged arm tower is estimated to be from 15 to 20 per cent less than for the rigid arm tower with which it has been compared. However, at certain locations in the line, namely, at angles and for certain long spans, hinged arms could not be used; for these cases rigid arms were required. In order that the insulation level might be maintained at these points, rigid wood arm assemblies were devised, the tension and compression elements being quite similar to those of the hinged assemblies. (See Figs. 1 and 8.)

### OTHER FACTORS OF TOWER DESIGN

One disadvantage of a double-circuit line in a "lightning" country is that construction economy tends to force the use of higher towers with consequent increased lightning exposure. This was particularly true in the case of the Osage-Rivermines line where the sharply rolling terrain continually offered opportunities for eliminating towers by the liberal use of tower extensions. Even with the exercise of some restraint in this respect, extensions varying in height from 4 to 16 ft. were justified for 40 per cent of the towers; this was on the basis that the saving in construction cost could not be offset by an intangible improvement in operation which might result from using more towers and shorter spans, and which in view of the high insulation of the line would be expected to be quite small anyway. As a concession to the electrical phase of this problem, however, the use of 16-ft. extensions on exposed ridges was limited to those locations where their application would not raise the conductors higher than at either of the adjacent towers.

### Table II—Loading Comparison Between Rigid Arm and Hinged Arm Towers

**RIGID ARM DESIGN**

**Vertical loads.** Weight of insulators and wires with ½ in. radial ice, for 1,500-ft. spans, multiplied by 1.5; dead load of tower, multiplied by 1.5.

**Lateral loads.** Wind load of 8 lb. per sq. ft. acting on wires with ½ in. radial ice, for 1,100-ft. spans, multiplied by 1.5; wind load of 15 lb. per sq. ft. on 1.5 times the area of material in one face of tower, multiplied by 1.5.

**Longitudinal loads.** Unbalanced load of any two broken wires at full load of 5,630 lb. for conductors and 4,400 lb. for ground wires, multiplied by 1.5.

**HINGED ARM DESIGN**

**Vertical and lateral loads.** Same as for rigid arm design.

**Longitudinal loads.** CASE 1. Unbalanced load of any one wire broken at full load but reduced to half tension by the arm swinging 90 deg. into the direction of the line; this loading combined with an impact load of equal amount (5,630 for conductors, 4,400 lb. for ground wires) multiplied by 1.5.

CASE 2. Unbalanced load of any two wires broken at full load but reduced to half tension by the arm swinging 90 deg. into the line (2,815 lb. for conductors and 2,200 lb. for ground wires) multiplied by 1.5.

CASE 3. Unbalanced load of any one wire broken at full load but reduced to half tension by the arm swinging 90 deg. into the line (2,815 lb. for a conductor or 2,200 lb. for a ground wire) multiplied by 1.5; this load combined with the unbalanced load of any one wire broken at full load but reduced to half tension by the arm swinging 90 deg. into the direction of the line, and an impact load of equal amount, (5,630 lb. for a conductor *or* 4,400 lb. for a ground wire) multiplied by 1.25. The effect of these loads should be considered only down to first panel point below bottom arms.

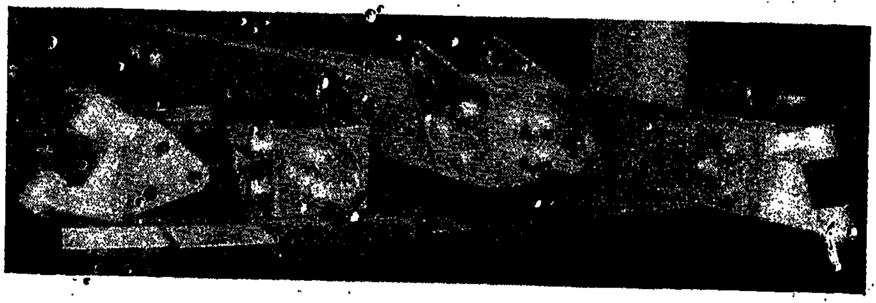

Fig. 7. Compression members of hinged wood arms showing method of applying clamps

Standard tower footing consisted of the familiar pyramidal framework resting on a square grillage. The only interesting departure from usual practise was suggested by the unevenness of the ground at the tower site. Sidehill leg extensions of 4 ft. or more had been provided for about 12 per cent of the towers, but many instances were found where a single leg extension of 2 ft. would be convenient. This need was met by designing a footing which projects 2 ft. out of the ground but which otherwise is similar to the standard anchor. The increased weight for one footing was only about 60 lb. and its advantages were many: it saved laborious cut and fill in material that was largely rock, and it permitted the establishing of higher grades with consequent gain in span lengths. Interchangeability of the two types of footings permitted the more general use of standard towers without the confusing inconveniences of substituting special leg and bracing material. More than half the towers in the line have one or more of these high footings.

### TOWER GROUND RESISTANCE

In view of the close relation between tower ground impedance and line performance under lightning conditions, the ground resistance of every tower was measured and recorded as an aid to analyzing any subsequent lightning outages. With ground wires detached, measurements were made by means of a direct reading megger ground resistance tester with a three-range scale (0 to 3 ohms, 0 to 30 ohms, and 0 to 300 ohms). Four readings were taken at each tower and the average taken as the tower ground resistance; each reading was taken between the tower base and two ¾-in. tool steel auxiliary ground rods driven into the earth to a depth of 3 ft. Positions of the auxiliary grounds were determined by tests. (See Fig. 9.) At many of the towers it was necessary to probe over a considerable area in order to find a place where the rods could be driven down 3 ft.; however, the arrangement of Fig. 9 was followed as closely as possible.

Results of these tests are shown in Fig. 10 from which may be seen that the footing resistances varied from less than 1 ohm up to 56 ohms, the average for all towers being 6.9 ohms. The measurements were made in an extremely dry season and soon after the towers were erected so that the earth had not settled around the

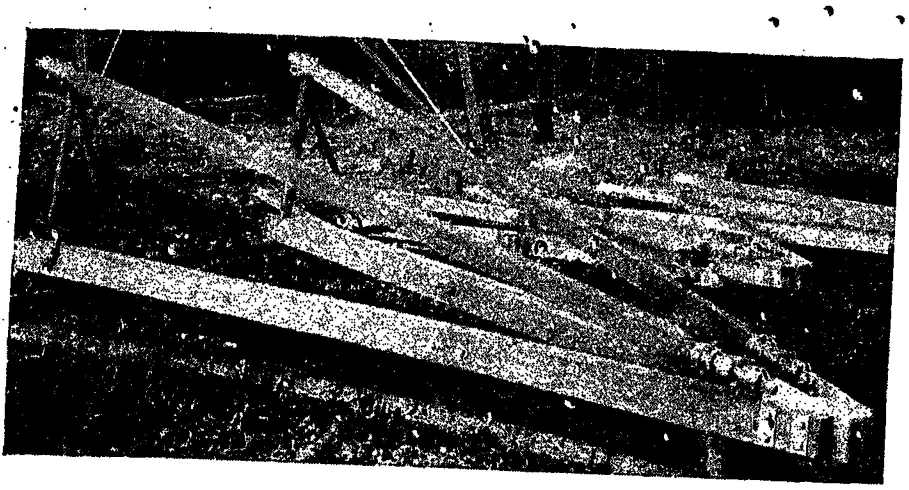

Fig. 8. Rigid wood arms as used at angles in the line and at certain long spans

footings. It is probable that after a few rains the earth will settle more compactly around the footings and that the ground resistances then will be somewhat lower.

Analysis of the curves in Fig. 10 show that 629 towers, or 83 per cent, of a total of 760 have ground resistances of 10 ohms or less. An examination of the 131 towers having resistances above 10 ohms brought out the fact that 46.1 per cent of these are set in sandstone, 37.5 per cent in limestone containing a large amount of chert, 14.1 per cent in limestone free from chert, and 2.3 per cent in sand and gravel. Approximately 5 per cent of the towers have resistances above 20 ohms, of which 70.5 per cent are set in sandstone, 20.6 per cent in limestone containing a large amount of chert, and 8.9 per cent in limestone free from chert.

No attempt is being made to lower any of the resistances at the present time because (1) average resistance of the line is low; (2) the high resistances are scattered along the line with not more than four consecutive towers having resistances above 10 ohms; and (3) the cost of lowering the high resistances would be excessive due to the fact that the footings on these towers are set in solid rock. Records of the locations of all flashovers will be kept and if it is found that the flashovers tend to concentrate on towers having high ground resistance, an attempt will be made to lower the resistance at these towers, or to provide some other form of protection.

Some additional data on the ground return path was obtained from a test made primarily for measuring the inductive effects on neighboring communication circuits. One 250,000-cir. mil copper conductor was grounded 85 miles from the power station, and energized from one terminal of a generator with its neutral grounded through a 4-ohm resistor. Readings taken on this test were: generator potential to neutral, 3,720 volts; current, 31 amperes; power 48 kw. (frequency 60 cycles).

From these data the resistance of the ground return path was computed to be 26 ohms, and the 60-cycle reactance of the circuit, 109 ohms. Based upon this reactance, the distance from the conductor to the center of the return path was computed to be 720 ft. The low value for the depth of the return probably is due to the small current used in the test.

### Line Laid Out from Aerial Survey

In conclusion, a word about the preliminary survey of the line location might not be amiss. This was unusual in that it was carried out entirely with the company's own aerial equipment and personnel. Planes and cameras are becoming available so generally that survey parties can be organized as readily for work in the air as on the ground.

The aerial method effected an enormous saving in time and expense in the location of this line. A series of contact prints from photographs taken at a constant height was assembled to give a 400-ft. scale map upon which the line was plotted. Sections of this assembled map were rephotographed for the use of the right-of-way department and an extra set of contact prints from the original films was used for stereoscopic study of the

# Propagation Constant of a Transmission Line

**Starting with the logarithmic variation of voltage and current along a transmission line, a derivation of the propagation constant is given in this article, depending only upon the application of Kirchoff's laws and simple hyperbolic trigonometry.**

By
**W. J. CREAMER, JR.**
Associate A.I.E.E.

University of Maine
Orono, Maine

WHEN a transmission line is infinite in length or is terminated in a load equal to its characteristic impedance, the voltage and current at various points along the line vary logarithmically as shown in Fig. 1, and are said to follow the laws of "normal attenuation." Considering, for example, the current wave, we may express the current at any point $d$ miles from the generator end as

$$I = I_0 e^{-\gamma d}$$

where $I_0$ is the current input to the line, $e = 2.7183$, and $\gamma$ is a constant for the particular line at a given frequency and is known as the propagation constant. This constant is a complex number, since there is a change in phase as well as in magnitude of the current as it progresses from the generator end, and is usually expressed as

$$\gamma = \alpha + j\beta$$

$\alpha$ being known as the attenuation constant and $\beta$ as the phase or wavelength constant. In the case of normal attenuation, therefore, the current at any point $d$ miles from the generator is completely expressed by the relation

$$I = I_0 e^{-\gamma d} = I_0 e^{-\alpha d - j\beta d} = I_0 e^{-\alpha d} \underline{/-\beta d}$$

That is, the current is reduced in magnitude by the "attenuation factor" $e^{-\alpha d}$, and shifted in phase by $\beta d$ radians.

The propagation constant of a transmission line usually is developed by means of differential equations, a method which does not recommend itself in an elementary discussion of the laws of normal attenuation. A derivation of this constant which depends only on the application of Kirchoff's laws and simple hyperbolic trigonometry is given below.

Every transmission line has four important linear constants: $R$, the series resistance per loop mile; $L$, the series inductance per loop mile; $C$, the linear capacitance per loop mile; and $G$, the shunt leakance per loop mile. Thus for a short section of line, a mile for example, there will be a series impedance of $Z_1 = R + j\omega L$ ohms, and a shunt impedance of

$$Z_2 = \frac{1}{G + j\omega C}$$

ohms. Let the diagram in Fig. 2 represent three unit lengths of 1 mile each. Calling the current in the first series element $I_0$, that in the second element $I_1$, and that

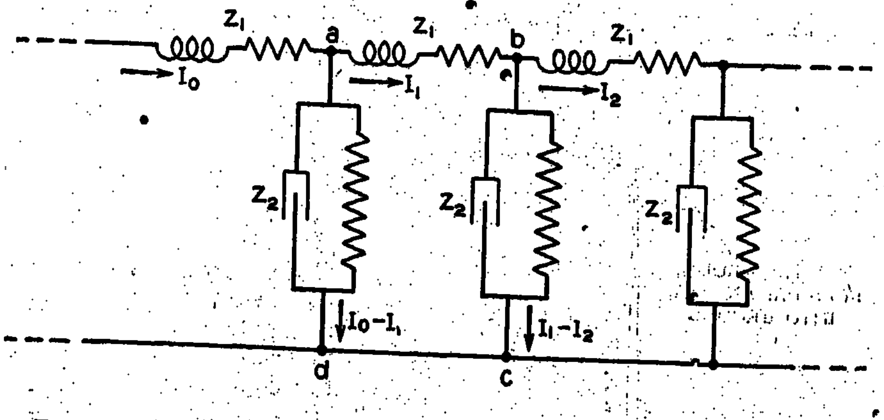

Fig. 2. Recurrent sections representing a transmission line

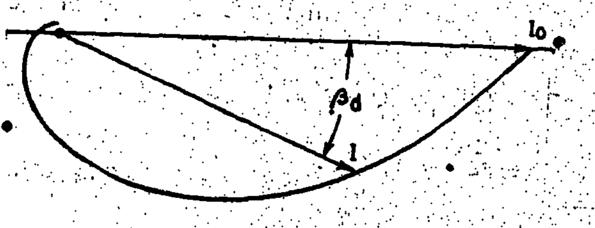

Fig. 1. Logarithmic variation of current with normal attenuation

---

Especially written for ELECTRICAL ENGINEERING. Not published in pamphlet form.

in the third $I_2$, we have the current through the first shunt path $I_0 - I_1$, and that through the next shunt path $I_1 - I_2$. Writing Kirchoff's law for electromotive forces in mesh *a-b-c-d*, we have

$$Z_1 I_1 + Z_2 (I_1 - I_2) + Z_2 (I_1 - I_0) = 0 \tag{1}$$

Dividing through by $Z_2 I_1$, we have

$$\frac{Z_1}{Z_2} + 1 - \frac{I_2}{I_1} + 1 - \frac{I_0}{I_1} = 0 \tag{2}$$

which when rearranged becomes

$$\frac{I_2}{I_1} + \frac{I_0}{I_1} = \frac{Z_1}{Z_2} + 2 \tag{3}$$

The two terms on the left of this equation are ratios of the currents in adjacent sections of the line. Now if normal attenuation obtains, it is evident that this current ratio will be the same for any two adjacent sections, and if we call this ratio $e^{\gamma}$, the above equation takes the form

$$e^{\gamma} + e^{-\gamma} - 2 = \frac{Z_1}{Z_2} \tag{4}$$

Extracting the square root of both sides and dividing by 2,

$$\frac{e^{\gamma/2} - e^{-\gamma/2}}{2} = \frac{\sqrt{Z_1/Z_2}}{2} \tag{5}$$

Now the left side of this equation is recognized as the hyperbolic sine of $\gamma/2$, which for small angles is approximately equal to $\gamma/2$; so that the relation in eq. 5 may be written

$$\gamma = \sqrt{(R + j\omega L)(G + j\omega C)} \tag{6}$$

This is the customary expression for the propagation constant of a transmission line.

# Transportation and a Nation's Diet

**Scientific developments have improved natural foods and made possible their wide distribution. This is the eighth article in The Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"**

By
RALPH BUDD

President, Burlington (Ry.) Lines

AMONG the many changes which have taken place in the living conditions of the average American during the past two decades, none is more striking than the change in diet. Ordinarily railway transportation is not thought of as affecting so vital a matter in the life of a people as an essential change in the kind of food they eat. Nevertheless, it is true that improved transportation of perishable products has brought about, or at least contributed greatly to, this change.

It is only in recent years that better refrigeration and expedited movement of fresh fruits and vegetables have brought to every city and village throughout the entire country every day in the year the products from those sections of the United States which specialize in horticultural delicacies. Advantages of a balanced diet containing fresh foods have been brought to the attention of the public by research and medical science, and the ability to grow these special products to greatest perfection has been developed simultaneously with the improvement in transportation which made practicable their distribution over such wide areas. In this way science in health, in horticulture, and in railway transportation, has coordinated to contribute towards happiness and longer life for many millions of people.

Perhaps the most remarkable example of how these changes affected a well-known product is the glorification of the lowly lettuce, which always has been a plant in the household garden. Some few years ago the fact was featured that certain vitamins which it contains are particularly desirable. Along with this came the development of head lettuce, which largely has taken the place of the old-fashioned leaf lettuce. The result has been that the shipment of lettuce over long distances has grown in the United States from 12,000 cars in 1920 to 55,000 cars in 1930.

Head lettuce is grown perhaps to greatest perfection along the Pacific Coast and in some of the western mountain valleys. A few years ago this would have prohibited its general use in the eastern states because of the perishable character of so delicate a plant. What has happened in this instance is typical of many others. Lettuce is not a new plant, but modern science and engineering have contributed to create a great consumptive demand which, in turn, has resulted in an attractiveness of the product as well as a distribution bringing about the growth of a great and extensive enterprise featuring an old-fashioned vegetable.

# Abstracts

## Of Papers Presented at the Winter Convention

INTERPRETIVE abstracts of the majority of papers presented at the A.I.E.E. winter convention (January 25-29, 1932) or articles based upon them, were published in the January issue of ELECTRICAL ENGINEERING. Interpretive abstracts of all remaining papers are presented herewith. Members vitally interested and wishing to obtain immediately pamphlet copies of any available papers are requested to use the order form appearing on p. 148 of this issue. In response to popular demand and within its space limitations ELECTRICAL ENGINEERING subsequently may publish certain of these papers, or technical articles based upon them.

## Aging and Elastic Hysteresis in Instrument Springs

By
R. W. Carson[1]
P. MacGahan[1]

ACCURACY of electrical measuring instruments depends as much on the quality of the control springs as on the design of the torque producing elements. However, judging from the work published on the subject, the design of high quality control springs has not received its proper share of attention.

Unstable effects found in the use of spiral instrument springs arise from a temperature change in the elastic modulus of the spring material, from secular change or aging in service, and from elastic hysteresis, all of which may under certain conditions introduce appreciable errors.

Secular change or aging in service was found to be caused by residual stresses in the spiral spring arising from the manufacturing process and was eliminated by a low temperature heat treatment. Elastic hysteresis was studied with the use of the grid glow micrometer. A study of the effect of composition and cold working, residual stresses and thermal treatment, temperature, intensity, and duration of loading on elastic hysteresis effects lead to an improved manufacturing process.

## An Automatic Oscillograph

By
C. M. Hathaway[6]
R. C. Buell[6]

AS A RESULT of the new era of extensive interconnection of large power systems and of the high speed operation of switches and circuit breakers, problems have arisen that only an oscillograph can solve; further an oscillograph for such applications must have characteristics that are not found in those designed for more general usage.

An oscillograph for such applications of course must be fully automatic because short circuits and faults are usually unanticipated, it should be able to take a considerable number of records successively whether the faults follow each other in rapid succession or are days or weeks apart, and it should start recording within one-half cycle of the beginning of the initiating disturbance. The automatic oscillograph described in this paper has been designed to meet these requirements, being intended primarily for the recording of chance and unanticipated disturbances in power systems and in electrical machinery. (A.I.E.E. Paper No. 32-47)

## Surge-Proof Transformers

By
H. V. Putman[25]

TWO FEATURES in connection with recently improved transformer construction are of special interest: First, without the use of shields to neutralize ground capacity, it has been possible to build shell type transformers in which the distribution of surge voltages is substantially uniform, and which are practically non-oscillating even for the longest surges; second, a major improvement in the impulse strength of the insulation has been made through the elimination of creepage surfaces from the entire insulation structure.

Ordinary methods of shielding, even though equalizing the voltage stress on the insulation between turns and coils, still permit high stress concentrations in the major insulation between windings and ground at the ends of the coil columns or groups. Furthermore, shielded transformers require most careful consideration in design, because of the introduction of large metal surfaces at line potentials in close proximity to the entire high voltage winding. The initial distribution in the new surge-proof transformers not only is substantially uniform within the winding, but the voltage stress is fairly uniformly distributed throughout the entire insulation structure. These results have been obtained simply by employing proper design proportions and coil arrangements, no shields being used. Further improvement in operation has been secured by many years of research on transformer insulation. (A.I.E.E. Paper No. 32-29)

## Effect of Transient Voltages on Power Transformer Design—IV

By
K. K. Palueff[8]
J. H. Hagenguth[8]

THE IMPACT of a surge on the high voltage terminals of a transformer produces transient voltages not only within that winding, but also within the low voltage winding and at its terminals. The latter voltage, discussed in this paper, is impressed on the network and apparatus connected to the secondary winding. The possibility of the transmission of high transient voltages through transformers is indicated by occasional failures during lightning storms of rotating apparatus connected to lines through transformers.

[6] General Electric Company, Schenectady, N. Y.
[8] General Electric Company, Pittsfield, Mass.
[17] Bell Telephone Laboratories, Inc., New York, N. Y.

The transient voltage on the secondary circuit may be considered as the result of superposition of four components; namely, electrostatic voltage, free oscillation in the high voltage winding, free oscillation in the low voltage winding, and electromagnetic induction. All four components depend to a different degree upon surge impedances and lengths of external circuits connected to the transformer. A study of these surge voltages enables definite conclusions to be drawn concerning the voltages produced on the secondary circuits, especially those caused by the electromagnetic component, which is of more general importance than the others. **(A.I.E.E. Paper No. 32-49)**

## Standard Decrement Curves

By
W. C. Hahn[22]
C. F. Wagner[2]

THE DETERMINATION of decrement in power system short-circuit currents frequently is necessary for circuit breaker and relay application. For this purpose certain standard decrement curves originally appearing in 1918 and revised in 1923, have been in general use. New decrement curves now have been derived to supersede the former ones, the new curves having been made desirable by the considerable progress in analysis of transients in synchronous machines, and to the use of symmetrical components for calculating unbalanced faults.

The new decrement curves take into consideration the fact that the a-c. component is made up of two exponential terms, and that the transient time constant varies with system reactance. Because the new curves are based upon the method of symmetrical components, a single set is applicable to three-phase, line-to-line, and line-to-ground faults. Distinction is made between machines with and without damper windings.

In addition to presenting these curves the paper includes also the underlying assumptions upon which they are based, the method of their application, and their limitations. **(A.I.E.E. Paper No. 32-53)**

## Calculation of Short Circuits on Power Systems

By
C. F. Wagner[2]
S. H. Wright[23]

CURVES presented in the companion paper "Standard Decrement Curves" are sufficiently accurate for most commercial work, particularly circuit breaker applications. Many special cases arise, however, for which these curves are not applicable. Of this character are relay applications on power systems involving several machines having different time constants and located unsymmetrically with respect to the fault. The individual branch currents in systems of this character may have widely different decrements and even may increase with time. Need, therefore, exists for a method of calculation which will take these individual variations into consideration. Such a method has been developed and has been termed the "internal voltage" method of calculation. It is particularly valuable in that it lends itself to the use of the calculating board and thus minimizes the labor involved.

In the present paper, part I is concerned with an extension of the standard decrement curves and part II with a discussion of the internal voltage method of calculation. Another important factor affecting short-circuit currents is the effect of the increase in exciter voltage during system faults. In part III is developed a semi-graphical method of determining this factor. **(A.I.E.E. Paper No. 32M4)**

## Decrement Curves for Specific Systems

By
W. C. Hahn[22]

GENERAL curves showing the current decay during system short circuits are given in the companion paper "Standard Decrement Curves." Inasmuch as arrangements of systems and characteristics of synchronous machinery vary considerably, a single set of general curves based upon certain assumptions as to system layouts, time constants, etc., will be only approximate, and in some cases considerably in error. It is desirable therefore to have available more accurate methods for obtaining decrement factors. It is the purpose of the present paper to describe the methods by which are obtained these more accurate decrement factors especially adaptable to specific arrangements.

The curves in the companion paper are constructed upon the idea of only one necessary calculation: that required to obtain the initial subtransient current in the short circuit. This may be called a one-point method. It is possible, however, to use the same curves in a more accurate manner by making two calculations based, for example, upon the initial subtransient and transient currents. Use then is made of the general decrement curves having the same ratio of subtransient to transient current as the actual system. A different procedure based on a three-point method may also be used. **(A.I.E.E. Paper No. 32M5)**

## Cobalt Magnet Steel

By
P. H. Brace[2]

IN THE iron-cobalt series, an alloy, $Fe_2Co$, having the highest known saturation intensity of magnetization was discovered. This led to the development of new and remarkable permanent magnet steels based on that alloy. The better of these showed residual induction equal to, and coercive forces three to five times as great as, those of the better magnet steels previously available.

As a result, relatively short and light permanent magnets capable of maintaining high field intensities became possible. Advantage of this has been taken in the construction of portable oscillographs; compasses, ignition magnetos and generators for aircraft; indicating and watt-hour meters; magnetic survey apparatus; telephone receivers and traffic control equipment.

The basic alloy $Fe_2Co$ alone is useless as a permanent magnet material. Its utility in this connection results from addition of less than eight per cent of alloying elements in fairly definite proportion, supplemented by appropriate heat treatment. From the magnetic standpoint the best composition contains the following approximate percentages: iron 54, cobalt 38, chromium 4, tungsten 2, carbon 0.95, manganese 0.5, and minor elements and impurities 0.55.

At the present price of two dollars per pound, such material cannot compete with the usual magnet steels on the basis of material cost per unit of magnetic performance and hence its use is economically justified only when savings of space or weight or its high coercive force can be capitalized. Compromise alloys of lower cost and less magnetic ability have become available.

---

[22] General Electric Co., Chicago, Ill.

[23] Buffalo Niagara and Eastern Power Corp., Buffalo, N. Y.

Cobalt represents the chief item of cost, but world resources, notably in Africa, Canada and the United States appear such as to give hope for improvement as a larger and more stable market develops. The reported consumption of high-cobalt magnet steel is now of the order of 75,000 lbs. per year. Six manufacturers of alloy steel in the United States are in a position to supply cobalt magnet steel. **Pamphlet copies not available.**

## High Capacity Rectifier Efficiency Improved by Sectionalizing

By
A. L. Atherton[2]

THE IDEA of the sectional type mercury arc rectifier is based on the obvious, but heretofore apparently unrecognized, fact that the best inherent possibilities are realized only in the smaller sizes. Efficiency, reliability, economy, and flexibility are all far better in small units than in large.

Multiple installations of the conventional small capacity units which have been available in the past are impracticable. The new sectionalized rectifier although built in sections, is installed, controlled, protected, and used as a whole, and the desirable qualities of the small rectifier thus are made available for the larger capacities while the disadvantages of sectionalizing are so reduced as to become negligible. **(A.I.E.E. Paper No. 32-50)**

## Time and Its Measurememt

By
E. W. Brown[24]

A TIMEKEEPER, whether terrestrial or celestial, may be considered as consisting essentially of a fixed dial and a moving pointer. A complete observation may be regarded as a comparison of the angles described by the pointers of two timekeepers between two signals.

The measurement of time is considered in this paper from the standpoint of securing the greatest possible accuracy for use in scientific studies, and far more accurately than needed in everyday life. Standard timekeepers are discussed and definitions of error, rate, and other factors are given.

The fundamental standard for time measurement is the rotation of the earth upon its axis. However, various errors are present in this standard and difficulties are involved in its observation. The difficulties in obtaining an absolutely accurate standard are exemplified in the fact that even the observatories taking the most accurate measurements show differences among themselves. **(A.I.E.E. Paper No. 32-51)**

## Modern Developments in Precision Clocks

By
Alfred L. Loomis[30]
W. A. Marrison[17]

ULTRA-PRECISE practical timekeepers of today can be placed within two classes, depending upon whether the restoring force is gravity, as in pendulum clocks, or elasticity, as in quartz crystal oscillators. The second class is a development of the last decade and was made possible by the vacuum tube and associated electrical circuits. Intercomparisons between timekeepers of the two classes provide a most valuable means for the study of changes in gravity and related phenomena.

The three gravity clocks most often recognized as precisio timekeepers are the Leroy, Riesler, and Shortt; one or more these are to be found in most of the important time laboratorie and astronomical observatories throughout the world. While th crystal clock assembly is more costly than that of a pendulu clock and requires more associated electrical equipment, it is believed that for many purposes it is decidedly superior becaus o its great versatility. **(A.I.E.E. Paper No. 32-52)**

## Direct Printing Over Long Non-Loaded Cables

By
M. H. Woodward[34]
A. F. Connery[34]

NOTWITHSTANDING the rapid progress that has been made in recent years in the application of automatic printers to landline operation, and the continued efforts to apply similar methods to the operation of long non-loaded submarine cables, the siphon recorder, which requires manual translation, still is used almost exclusively in the operation of such circuits. While the recently developed loaded type of submarine cable possesses characteristics which permit of its being operated with a modified form of landline multiplex printing system, the numerous attempts to develop and apply a satisfactory direct printing system to non-loaded cables have not met with complete success.

It is the purpose of this paper to outline briefly the various factors which enter into this problem and to describe a new type of cable printer which has been developed and placed in successful operation on cables between London and New York and also between New York and points in Central and South America and the West Indies. A method is described for the electrical conversion of the non-uniform length combinations of the cable Morse code into a modified five unit code and its application to printers on long non-loaded submarine telegraph cables.

## Vector Theory of Circuits Involving Synchronous Machines

By
I. H. Summers[37]

PREVIOUS publications have shown that calculations of the performance of a synchronous machine may be simplified by the use of two scalar impedance operators which apply separately to the component of armature current which magnetizes in the axis of the poles, and to the component which magnetizes in the axis of the interpolar space.

The present paper describes a method of combining these two scalar operators into a single vector operator which applies directly to the total current. With the new operator it becomes possible to write out the complete equations which apply to various numbers of interconnected machines, under various operating conditions, as readily as would be possible if each machine were replaced by a fixed source of voltage operating through a constant value of impedance. The effect is to simplify the labor greatly and thus to extend the scope of synchronous machine analysis, particularly in cases in which more than one machine is involved. It is believed that the theory developed will be of value to engineers who are working on problems such as stability, hunting, pulling into step, and other problems of this general character which involve detailed analysis of the operation of synchronous apparatus under transient conditions. An introduction to this article has been prepared by R. H. Park. **(A.I.E.E. Paper No. 32-48)**

# Great Lakes District to Meet at Milwaukee

COOPERATION of local educators, manufacturers' representatives, and public utility men has enabled a technical program covering a variety of interests to be arranged for the three-day meeting of the A.I.E.E. Great Lakes District, No. 5, which will be held at Milwaukee, Wis., March 14-16, 1932. Headquarters will be in The New Pfister Hotel. In addition to the technical program, Milwaukee and its environs with their well known industries should hold much of unusual interest for the visitor.

### TECHNICAL SESSIONS

Three technical sessions will be held, one on each day of the meeting. The first session embraces papers in the fields of electrophysics, research, and communication. The second session will bring forth papers on the development of the Waukegan Station and its electrical design features; another paper will describe a 115,000-kw. turbo-alternator; two others will treat line wire insulation and factors affecting spark-over of insulators and bushings. The third session will be devoted to problems in connection with railway electrification and transmission. A student session also will be held and papers by the students within the District will be presented.

The many interesting inspection trips and entertainment features being arranged will be announced later.

### HOTEL RESERVATIONS

Members should make their reservations by writing directly to the hotel preferred. Rates for the headquarters hotel, The New Pfister, as well as several other hotels are given in the accompanying table.

## Tentative Technical Program

### Monday, March 14

**Session No. 1**—*Presiding:* C. F. Harding

The Proximity Effect and Its Application to the Concentration of Heating Currents, Edward Bennett, University of Wisconsin.

*A General Method of Gaseous Tube Control, Carroll Stansbury, Cutler-Hammer, Inc.

*Electrical Instruments in the Gas Industry, E. X. Schmidt, Cutler-Hammer, Inc.

*Toll Switching Plan for Wisconsin, W. C. Lallier, Wisconsin Telephone Co.

*Police Teletypewriter System, R. E. Pierce, American Tel. and Tel. Co.

### Tuesday, March 15

**Session No. 2**—*Presiding:* R. F. Schuchardt

*Development of the Waukegan Station of the Public Service Company of Northern Illinois, J. L. Hecht, Public Service Company of Northern Illinois.

*Electrical Design Features of Waukegan Station, E. C. Williams, Public Service Company of Northern Illinois.

*115,000-Kw. Turbo-Alternator, R. B. Williamson, Allis-Chalmers Mfg. Co.

*Weatherproof Insulation for Line Wires, C. F. Harding, L. L. Carter and J. W. Olsen, Purdue University.

*Factors Affecting Spark-Over of Insulators and Bushings, W. L. Lloyd, General Electric Co.

### Wednesday, March 16

**Session No. 3**—*Presiding:* J. H. Foote

*A 60-Cycle Primary Transmission System, C. D. Brown and E. W. Hatz, The Milwaukee Elec. Ry. & Lt. Co.

*The Mercury Arc Rectifier Applied to A-C. Railway Electrification, O. K. Marti, Allis-Chalmers Mfg. Co.

*Mercury Arc Rectifier *Versus* Rotary Converter Automatic Railway Substations, O. M. Ward, The Milwaukee Elec. Ry. & Lt. Co.

*An Improved Type of Limiting Gap for Protecting Station Apparatus, A. O. Austin, Ohio Insulator Co.

Variation in Diameter and Spacing of Suspension Insulators, J. J. Torok and C. G. Archibald, Westinghouse Elec. & Mfg. Co.

Advance copies of papers for discussion will be sent to members as soon as available, upon written request to A.I.E.E. headquarters, 33 West 39th Street, New York, N. Y. Please indicate by title and name of author the paper or papers requested. At the meeting usually five minutes is allowed each discussor. When a member signifies desire to discuss papers on other subjects or groups he shall be permitted a five-minute period for each subject or group. Discussions are not reported; typewritten copies should be left with the presiding officer.

---

*These papers are under consideration for presentation at the Great Lakes District meeting, but up to the date of going to press have not been officially placed upon the program.

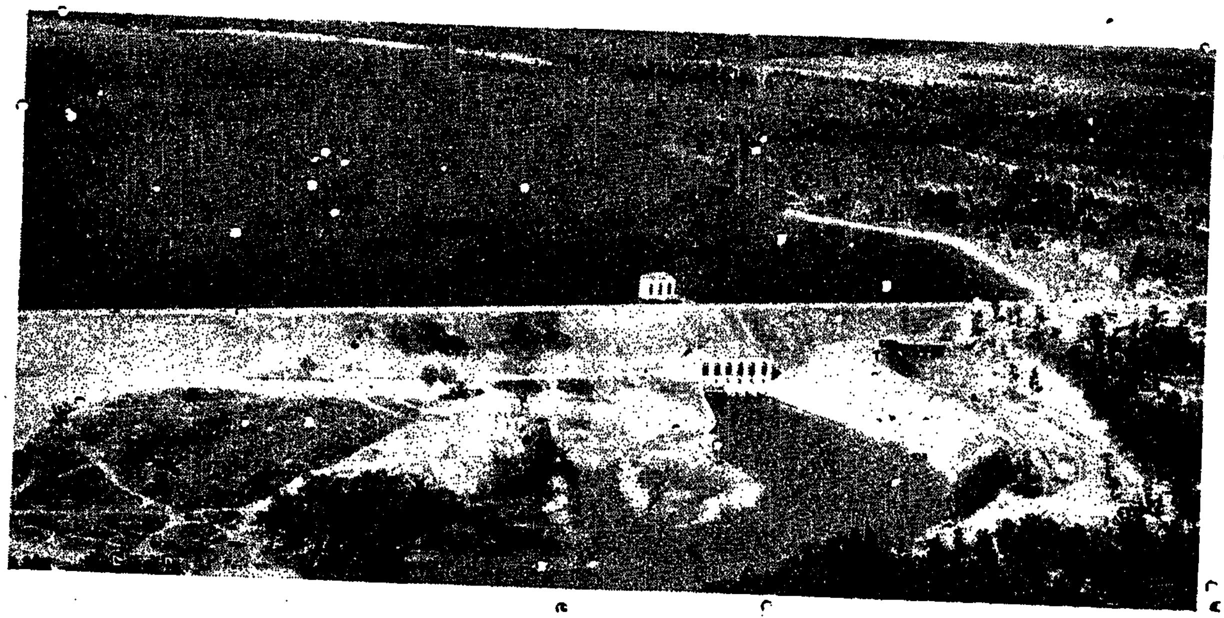
| | Double | $3.00–$4.00 | $5.00–$10.00 | $20.00 |

**Date of District No. 2 Meeting.**—Announcement is made by K. A. Hawley, chairman of the Baltimore Section, that the general committee which is arranging the details for the Middle Eastern (No. 2) District meeting in Baltimore, Md., October, 1932, has decided that this convention will be held October 10-14 inclusive. The tentative program arranged includes registration and sessions on October 10 with sessions continued on the following days. A trip to the Safe Harbor hydroelectric plant on the Susquehanna River is planned for October 13.

**Winter Convention Report.**—At the time of going to press for this issue, the 1932 winter convention of the Institute was in progress at the Engineering Societies Building in New York City. A full report of this convention will be given in subsequent issues of ELECTRICAL ENGINEERING.

# Michigan's Largest Dam



HARDY DAM on the Muskegon River supplies the Consumers Power Company over a 48-mile 140-kv. transmission line to Grand Rapids, Michigan. This dam is the largest in Michigan, and among the largest earth dams in the world built on an earth foundation. The dam itself is about 100 ft. high and the pond created has a volume of 160,000 acre ft. The three fully automatic generators are of the vertical type, each rated at 12,500 kva. 60 cycles. Direct-connected main and auxiliary exciters are mounted above the main thrust bearing. The thrust bearings on the generators carry the load of the generator rotors, the waterwheel and the hydraulic thrust of the water passing through the wheel, amounting to a total of approximately 290,000 lb. The generators are enclosed completely and are equipped with water tube air cooling condensers, located below the operating floor which is at exciter level.

---

# A.I.E.E. Prizes for Technical Papers

Authors who are presenting papers before the Institute during the calendar year 1932, and others who may wish to submit papers for prizes, would do well to bear in mind that such papers are eligible for consideration for Institute prizes. These awards are made each spring for the preceding calendar year, and fall into two main classes, national and District prizes.

### NATIONAL PRIZES

The national prizes which may be awarded at the discretion of the committee on award of Institute prizes are as follows:

1. Prizes for best papers in (1) *engineering practise*, (2) *theory and research*, and (3) *public relations and education*
2. Prize for initial paper
3. Prize for Branch paper

Each national prize shall consist of a certificate of award issued by the Institute and $100 in cash.

The national prize for best paper in each of the three classes indicated may be awarded to the author or authors of the best original paper presented at any national, District, or Section meeting of the Institute.

The national prize for initial paper may be awarded to the author or authors of the most worthy paper presented at any national, District, or Section meeting of the Institute, provided the author or authors have never previously presented a paper which has been accepted by the technical program committee.

The national prize for Branch paper may be awarded to the author or authors of the best paper based upon undergraduate work presented at a Branch or other Student meeting of the Institute, provided the author or authors are Student Branch members.

All papers submitted for prizes (except for the Branch paper prize) must be written by members of the Institute. When papers are written jointly, the cash awards shall be divided, and a certificate shall be issued to each author.

All papers approved by the technical program committee which are presented at any meeting will be considered by the committee on award for the best paper prizes without being formally offered for competition. All papers other than those presented to the technical program committee must, in order to receive consideration, be submitted in triplicate with a written communication to the national secretary on or before February 15 of the year following the calendar year in which they were presented. This may be done by the author or authors, by an officer of the Institute, or by the executive committees of Sections, or Geographical Districts.

### DISTRICT PRIZES

The following District prizes may be awarded each year in each Geographical District of the Institute.

1. Prize for best paper
2. Prize for initial paper
3. Prize for Branch paper

Each District prize shall consist of a certificate of award issued by the officers of the Geographical District and $25 in cash. It may be awarded only to an author who, or to co-authors of whom at least one, is located within the District, and for a paper presented at a meeting held within, or under the auspices of, the District. When papers are written jointly, the cash awards shall be divided and a certificate shall be issued to each author.

The District prize for best paper may be awarded for the best paper presented at a national, District, or Section meeting.

The District prize for initial paper may be awarded for the best paper presented at a national, District, or Section meeting, provided the author or authors have never before presented a paper before a national, District, or Section meeting of the Institute.

The District prize for Branch paper may be awarded for the best paper based on underground work presented at a Branch or other Student Meeting of the Institute, the author or authors of which are Student Branch members.

All papers to be considered in competition for District prizes must be submitted in duplicate by the authors or by the officers of the Branch, Section, or District concerned to the District committee on awards on or before January 10 of the year following the calendar year in which the papers have been presented.

All papers submitted for prizes (except for the District prize for Branch paper) must be written by members of the Institute. When papers are written jointly at least one of the authors must be a member of the Institute.

Copies of a pamphlet entitled "National and District Prizes" may be secured, without charge, upon application to Institute headquarters.

**Federal Radio Act Passes Senate.**—On January 4, 1932, the U. S. Senate passed Senate bill 1,037 which would amend the federal radio act of 1927 so as to transfer the existing radio division from the Department of Commerce to the Federal Radio Commission. This is a reorganization measure which will consolidate and simplify the federal government's activities in regulation of radio matters.

## Montefiore Award to be Made Soon

Announcement has been made of the conditions of the George Montefiore prize which will be awarded this year by the Institut Electrotechnique Montefiore of Liege, Belgium. The prize consists of the interest on 150,000 Belgian francs at 3 per cent and is given triennially in international competition for the best original work presented on scientific advancement or on progress in the technical application of electricity in any field. Only achievements made public during the three years preceding the award will be considered. Manuscripts may be submitted in English, in printed or typewritten form, and must be in the hands of the jury not later than April 30, 1932.

The awarding of the prize is in the hands of a jury of ten electrical engineers composed of five from Belgium and five from other countries, acting under the president of the Institute Electrotechnique Montefiore, Omer De Bast. The award is administered through the Association des Ingenieurs Electriciens, or national electrical engineering society of Belgium, with headquarters at Rue Saint Gilles, 31, Liege, Belgium.

## Bibliography on Conductor Vibration

The subcommittee on steel transmission towers and conductors of the power transmission and distribution committee has been working on the problem of vibrating and dancing conductors. As a method of assisting research in this problem, a bibliography has been prepared on vibration, using this term in its broader interpretation.

In compiling this bibliography, all literature available both in this country and abroad has been reviewed to give as complete a reference as possible on this subject. There are six general headings under which these articles have been grouped and which also indicate the relation of associated problems. These six classifications are:

1. Vibration in electrical cables exposed to light winds.
2. Jumping or dancing conductors due to partial glaze coatings and varying ice formations.
3. Wind effects on structures.
4. Wire rope research.
5. Sound and noise.
6. Fatigue and allied researches.

This bibliography is now in mimeographed form and contains a total of 176 items. Any investigators working on this subject may obtain a copy from the chairman of the subcommittee, R. N. Conwell, Public Service Electric and Gas Co., 80 Park Place, Newark, N. J.

## Columbia University Offers E.E. Scholarships

Each year the governing bodies of Columbia University have placed at the disposal of the Institute a scholarship in electrical engineering in the school of mines, engineering, and chemistry of Columbia University, for each class. The scholarship pays $350 toward the annual tuition fees which vary from $340 to $360 according to the details of the course selected. Reappointment of a student to the scholarship for the completion of his course is conditional upon the maintenance of good standing in his work.

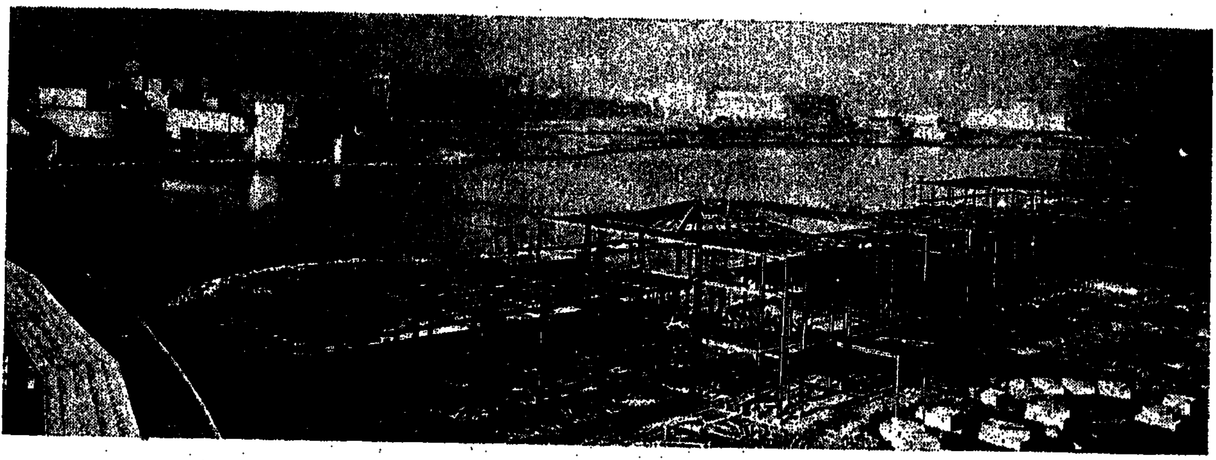
Applicants must meet the regular admission requirements. All letters of application should be addressed to F. L. Hutchinson, National Secretary, A.I.E.E. 33 West 39th St., New York, N. Y., and should give age of candidate, place of birth, education, references, photograph, and reference to any other activities, such as athletics or working one's way through college. The last day for filing applications for the year 1932-33 will be June 1, 1932.

The course at the Columbia School of Mines, Engineering, and Chemistry is a three-year course on a graduate basis. Candidates must have had a general education including considerable work in mathematics, physics, and chemistry. Three years of preparatory work with special attention to the three preparatory subjects mentioned in a good college or scientific school should be sufficient. A college graduate with a B.S. degree in engineering generally can qualify to advantage. The candidate is admitted on the basis of his previous collegiate record without undergoing special examination. Other qualifications being equal, members of Student Branches of the A.I.E.E. will be given preference.

The purpose of this advanced course is to produce a high type of engineer, trained in the humanities as well as in the fundamentals of his profession. It is hoped that Enrolled Students and others qualified will show a keen interest in this scholarship.

**A windowless building,** the first of its kind in the United States, is under construction at Fitchburg, Mass., for the Simonds Saw & Steel Company by the Austin Company of Toledo, Ohio. With solid wall and roof construction and with neither windows nor skylights this new industrial plant is planned to contain 5 acres of floor space and designed to cover practically two city blocks. Francis Keally, New York, is the architect responsible for the design of this $1,500,000 plant, and predicts greatly superior working conditions within the new structure as compared with the more usual design. Elaborate systems to provide high intensity lighting, regulated ventilation absorption of interior noise and elimination of exterior noise are expected to be installed in the building. The lighting system is planned to supply

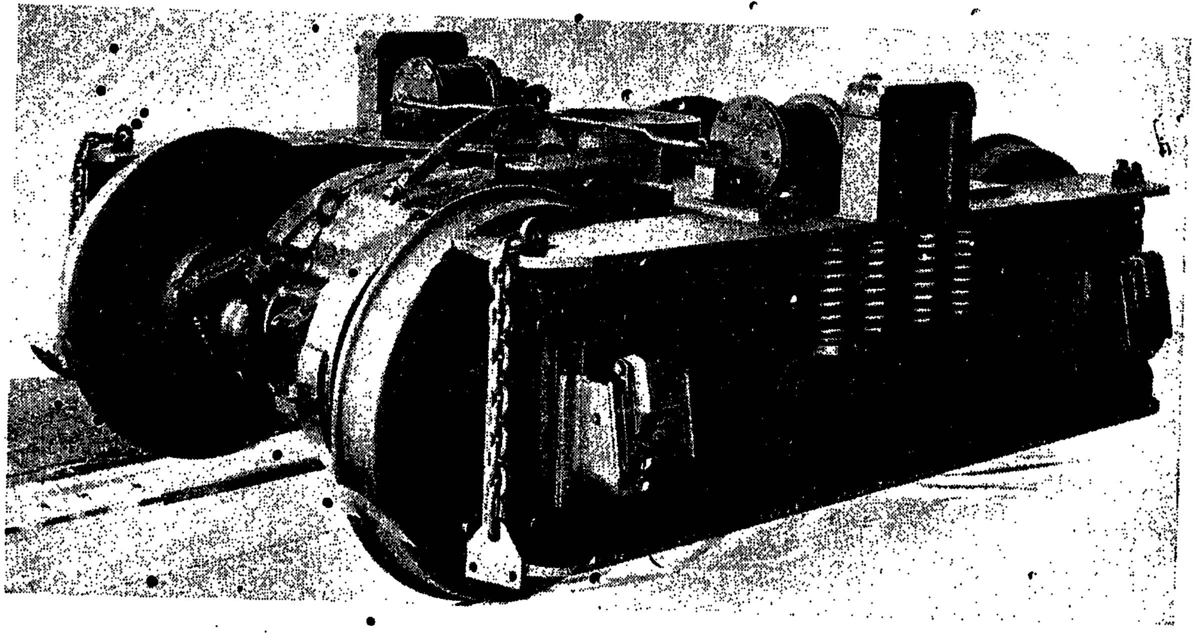
## Construction Progresses for World's Fair



THIS interesting study of part of the electrical group of "A Century of Progress," Chicago's 1933 World's Fair, gives an idea of the rapid progress being made in its construction. When completed, this group will comprise three buildings, a radio building, a communications building and an electrical building. The group will join the mainland site of the exposition by a bridge. In the background of this picture may be seen a view of the 1933 World's Fair site, from the Hall of Science at 16th Street north to the Shedd Aquarium.

a proportion of ultraviolet radiation and a harmonizing color scheme for machinery, and interior decoration is expected to complete the provision of excellent working conditions.—*Michigan Technic.*

## An All-Welded Switching Locomotive



The complete structure of cab, under-frame, and trucks of seven locomotives constructed by the General Electric Company for switching service at Bush Terminal, Brooklyn, N. Y., is fabricated entirely from structural steel shapes and plates, and is arc welded throughout. There are no rivets, and bolts have been used only for those portions requiring occasional removal or renewal. One of the trucks, with motors installed, is shown in the illustration. Each locomotive is of the 60-ton type and has a Diesel-electric power plant, using a 300-hp. engine. The truck frame consists essentially of three members: two side frames of 26-in. 151-lb. girder beams with a 22-in. 108-lb. girder beam serving as the bolster. The bolster beam is welded directly to the side members, the joint surfaces being reinforced with heavy gusset plates and brace plates. All welds on these members are continuous. On the cab, both continuous and intermittent welding are used.

## N.E.L.A. Relay Handbook Reissued With Supplement

The Relay Handbook, originally issued by the National Electric Light Association in 1926, has just appeared in its second edition as "Relay Handbook and Supplement." It was thought best, by the subcommittees of the N.E.L.A. and the protective devices committee of the A.I.E.E. concerned with the revision of the original publication, to bring the book up to date by the addition of supplements to the several sections. All material contained in the supplements is believed to be new and all new relay schemes described have been tested in service unless stated to the contrary.

With regard to "Section I—General Information," it should be kept in mind that while the supplement is devoted entirely to a presentation of the latest symbols used in practise for electric power and wiring, and shortly to be offered for approval as an American Standard, this does not carry with it the inference that the definitions also contained in Section I of the 1926 edition and taken from the 1922 edition of the A.I.E.E. Standards have remained unchanged since that date. Reference to the latest standards of the A.I.E.E. should be made whenever use of the definitions is contemplated. For complete information relative to this handbook apply to N.E.L.A. headquarters, 420 Lexington Avenue, New York, N. Y.

## Lightning Arresters Tested at High Energy

A test has been made which is stated to be the first ever performed on a full size high voltage lightning arrester with surge energy comparable to that met in the field. The newly installed 3,000,000-volt 36,000-watt-second lightning generator at the Sharon Works of the Westinghouse Electric & Manufacturing Company was used in this test.

A 230-kv. station type auto-valve arrester, such as would be used for the protection of 230-kv. transformers, was set up in parallel with the 64-in. relief gap recommended for this voltage class, and a string of fourteen suspension insulators. Surges of various magnitudes and steepness of front were applied from the 3,000,000-volt surge generator. Finally, the full output of the surge generator was discharged through the arrester, the wave front being about three times as steep as the steepest lightning surge yet recorded in the field. The lightning arrester prevented flashover of the 64-in. coordinating relief gap in all cases. In the last test described above, between fifteen and twenty thousand amperes passed through the lightning arrester. However, it is claimed that careful examination showed the arrester to be unharmed.

**Joint Meeting on Metals.**—On Feb. 18, 1932, Sections of the American Society for Testing Materials and the American Institute of Mining and Metallurgical Engineers will hold a joint meeting in the auditorium of the Engineering Societies Building, 33 West 39th Street, New York, N. Y. The general theme of the meeting will be metals; Dr. F. O. Clements will discuss the subject "Limits of our Knowledge of the Properties of Metals," and Prof. H. F. Moore will address the meeting on "Test Results and Service Values of Metals." From long and active connection with the metals field, both of these men are qualified to discuss these subjects ably and with authority. All interested in the subject of metals are cordially invited to attend. The meeting is scheduled to begin at 8 p.m.

**Graduate Courses in Acoustics and Physics.**—Beginning on February 5, 1932, two new graduate courses will be given on Friday evenings at the Polytechnic Institute of Brooklyn, New York. They will be given by Prof. R. B. Lindsay, visiting professor of theoretical physics from Brown University, and are entitled "Acoustics" and "Statistical Theories in Modern Physics."

The course in acoustics will begin with a rapid review of the simpler properties of sound waves and will proceed through the development of fundamental mathematical theory to the more important practical problems. The second course will include an introduction to the use of statistical methods in physics, followed by a presentation of the new statistics of Bose-Einstein and Fermi-Dirac. The latter viewpoints will be applied to the more important electrical and thermal problems. While the treatment will be mathematical, the principal emphasis will be upon the physical significance of the results.

# American Engineering Council

## Annual Meeting and Election of Officers

At the annual meeting of the American Engineering Council in Washington, D. C., January 14-16, 1932, W. S. Lee (A'04, F'13, past-president) of Charlotte, N. C., was elected president for the coming two years. He succeeds C. E. Grunsky of San Francisco, Calif. Gen. R. C. Marshall, Jr., and L. B. Stillwell (A'92, F'12, past-president) both of New York, N. Y., were respectively elected and reelected vice-presidents. Farley Osgood (A'05, F'12, past-president) of New York, N. Y., was named treasurer to succeed Dr. H. E. Howe of Washington, D. C.

The following representatives of the Institute were designated to serve on the administrative board of the Council for the year 1932: C. O. Bickelhaupt, H. A. Kidder, R. F. Schuchardt, C. E. Skinner, and C. E. Stephens.

### Administration of Public Works

Steps also were taken at the annual meeting to aline the engineering profession in support of legislation to create an administration of public works in accordance with the recommendation of President Hoover in his last message to Congress.

The Council will work for the enactment by the present Congress of the bill introduced in the House by Representative Cochran of Missouri "to accelerate public construction in periods of business depression through the creation of an administration of public works and to provide for a more effective coordination and correlation of the public works functions of the government." Numerous amendments to the Cochran measure will be urged upon Congress by the engineers.

The Council has been advocating public works reorganization since it was founded in 1919 under the leadership of Mr. Hoover. Favorable action by Congress now is believed to be probable owing to the disappointment of the people over the failure of public works activity to provide the measure of unemployment relief which had been expected. The taxpayers, it is believed, are aroused to the point where they will demand such a realinement of public works bureaus and services as will respond to national needs in times of economic distress.

Passage of this legislation, it was asserted in the Council's discussion, will be a large factor in bringing about economies in the federal administration and in balancing the federal budget. Presidential sponsorship of public works consolidation will, it was felt, evoke a sympathetic response from both parties in Congress inasmuch as the ends sought are non-political. Many millions of dollars annually will be saved if the public works proposal becomes law, it is held.

The Cochran bill provides for the appointment by the President of an administrator of public works to hold office for fifteen years at an annual salary of $15,000, and for the establishment in the administration of public works of a group of bureaus, each headed by a director, to administer the various public works services.

### Requirements of Administrator

The Council will ask Congress to require that the administrator "shall by training and experience be qualified to administer the affairs of the administration of public works and to evaluate the technical principles and operations involved in the work thereof."

On the motion of L. B. Stillwell (A'92, F'12, past-president) of New York, N. Y., the Council voted opposition to the plan to place the national commission of fine arts under the jurisdiction of the administration of public works. Inclusion of the commission in the administration, Mr. Stillwell said, might deprive the government of the patriotic service of the nation's leading architects.

The engineers will seek an amendment to the Cochran bill placing the design, construction, maintenance, operation and repair of ferries, barges, hospitals, lighthouses, prisons, storehouses, docks, and flood control works under the control of the administrator of public works.

Another engineering amendment would enable the administrator to employ from time to time, outside professional or technical service of competent persons, firms, or corporations, for the architectural and engineering designing, planning and construction of such federal buildings and works as may be placed under his jurisdiction.

Enlargement of the authority of the administrator of public works is asked by the Council in the following amendment:

> "Under the direction of the President, the administrator of public works shall have the power by order or regulation, to consolidate, eliminate, or redistribute the functions of the bureaus, offices, agencies, activities and services in the administration of public works and to create new ones therein and by rules and regulations not inconsistent with law, shall fix the functions thereof and the duties and powers of their respective executive heads."

In adopting the public works program, the Council acted upon the recommendations of the public affairs committee headed by R. F. Schuchardt (A'03, F'13, past-president) of Chicago, Ill.

### Green Bill

The Council sanctioned the measure introduced by Representative Green and sponsored by the American Institute of Architects, authorizing the Secretary of the Treasury to employ private architects in the designing and planning of public buildings. Engineers, however, would make the employment of private architects optional with the Treasury instead of mandatory as provided in the bill. Gen. R. C. Marshall, Jr., of New York, N. Y., head of the construction division of the War Department during the World War, declared that the principle of the bill should apply to all government agencies. The Fulmer bill, which is along the same lines as the Green bill, was opposed. Neither measure would be necessary if the Cochran bill becomes law.

Representatives of the American Institute of Electrical Engineers in attendance were: F. J. Chesterman, W. S. Lee, I. E. Moultrop, Farley Osgood, W. S. Rodman, R. F. Schuchardt, C. F. Scott, C. E. Skinner, and L. B. Stillwell.

## Patents Committee Invites Public Hearings

The patents committee of the House of Representatives is holding public hearings in Washington from January 20, 1932 to March 1, 1932. As indicated in the following four paragraphs taken from a letter under date of January 8, 1932, from W. I. Sirovich, chairman of the committee on patents of the House of Representatives, to L. W. Wallace, executive secretary of the American Engineering Council, the purpose of these hearings is to assist the committee in planning legislation that will meet the approval of the Congress of the United States.

> "Many bills are introduced at each session of Congress for the purpose of amending the patent laws, nevertheless they remain substantially as they were enacted in 1836. As chairman of the committee on patents and copyrights of the House of Representatives of the 72nd Congress, I desire to learn whether the changed economic conditions require amendment, or change, in our patent statutes. To that end I propose to have public hearings before the committee on patents at Washington from January 20, 1932 to March 1, 1932.
>
> "You are cordially invited to attend and give the committee on patents the benefit of your opinion as to what, if any, legislation should be enacted.
>
> "Will you please give this communication as much publicity as possible and invite members of your organization, and any officers or committees interested, to appear before the committee and indicate what, if any, legislation should be enacted.
>
> "As far as possible I wish to meet the convenience of those not residing in Washington, and a definite date for appearance before the committee may be arranged by writing me, indicating how much time is wanted and about when."

**College Course in Radio Offered.**—Through its extension division in Milwaukee, the University of Wisconsin is giving a course in radio communication. This training is of a semi-professional nature with the object of training young men for positions existing in a field between the skilled craftsman and the trained professional engineer. The work is substantially of collegiate grade requiring for entrance a high school education or the equivalent. Completion of the course requires the full time of a student for two semesters, or evening classes over a period of two years. The course may be taken by correspondence also. Satisfactory completion qualifies a student for the government examination for a second-class commercial operator's license.

**Ambrose Swasey** (HM'28) was honored on his eighty-fifth birthday by a luncheon tendered him by officers of the Cleveland (Ohio) chamber of commerce on December 19, 1931. On this occasion about a hundred letters of congratulation were presented to him, and a preview of the Swasey portrait painted by Philip A. de Laszio was made. Among the speakers was Dr. C. W. Rice (A'97-F'12) who paid tribute to Mr. Swasey's many contributions.

# Letters to the Editor

## Discussion of "E.E." Articles Invited

Institute members and subscribers hereby are invited to discuss in these columns any of the articles appearing in ELECTRICAL ENGINEERING. Heretofore discussion has been solicited specifically only on those articles appearing in the Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?" Nevertheless, since the introduction of these columns in the September 1931 issue, some readers already have sent in letters on other articles, a few of which were published in subsequent issues.

Because of the many letters received, it is not feasible to publish all, but an endeavor will be made to include those which appear to be of the most general interest. The shorter letters in general are more popular, and hence conciseness is a desirable quality in all cases. ELECTRICAL ENGINEERING reserves the right to publish letters either in full or in part.

## Warning to Welders

*To the Editor:*

I hope you will feel it your duty to issue this warning to welders:

They should not light their cigarettes or cigars from the glowing tip of the electrode when it is still in the electrode handle. This is a very clever or handy trick but some day when their cigarette is damp or their shoes are damp they will get a shock. This can best be described as if a mule kicked them in the jaw and loosened all their teeth. Such a shock might prove fatal if they are working on a scaffold or in a tank or some such place where the release of the tension would throw them off balance. It is always spoken of as "a shock throws one." As a matter of fact, it is the cutting of the rope which you have been straining against trying to release yourself from the muscular tension that "throws you."

Very truly yours,
C. J. HOLSLAG (M'19)
President, Electric Arc Cutting & Welding Co., 152 Jelliff Avenue, Newark, N. J.)

## Nerve Injuries from Electric Shock

*To the Editor:*

I should like to enter protest against the inclusion in ELECTRICAL ENGINEERING of further articles of the type exemplified by "Nerve Injuries from Electric Shock" in the December 1931 issue. I do not believe the average engineer is interested in a subject so remotely connected with engineering.

I suppose the medical journals will still be filled with this class of work, but I do not believe it belongs in quantity in our transactions. It is bad enough to use rats in this work; if we ever use dogs it were better for us if we passed out of existence as a body at that time. I do not believe that kind of engineering is acceptable "On High," and I hope it will not be popular here below.

Pardon if my sincerity has carried me too far.

Yours very truly,
F. G. STRONG (A'91-F'13 and Life Member) 120 Hartford Ave., Wethersfield, Conn.

## Computing the Value of $\sqrt{2}$

*To the Editor:*

Having an occasion to compute the value of the form-factor of sine wave ($\pi/2\sqrt{2}$) to the fifth place of decimals, I felt interested in developing some simple method of computing the value of $\sqrt{2}$, to a high degree of precision. The following two methods evolved in the course of the study might interest some of your readers:

METHOD 1—Expansion into a rapidly conververgent series:

$$2 = \frac{100}{49}(1 - 0.02)$$

therefore

$$\sqrt{2} = \frac{10}{7}(1 - 0.02)^{\frac{1}{2}}$$

By the binomeal theorem

$$\sqrt{2} = \frac{10}{7}\Big[1 - (a + 1/2\, a^2 + 1/2\, a^3 + 5/8\, a^4 + 7/8\, a^5 + \frac{21}{16} a^6 + \frac{33}{16} a^7 + \ldots\ldots \frac{1 \times 3 \times 5 \times 7 \ldots (2n-3)}{(1 \times 2 \times 3 \times \ldots\ldots n)} a^n\Big]$$

where

$a = 0.01$

or

$$\begin{aligned}\sqrt{2} = \frac{10}{7}[1 - {} & 0.01 \\ & 0.00005 \\ & 0.0000005 \\ & 0.00000000625 \\ & 0.0000000000875 \\ & 0.0000000000001312\mathit{5} \\ & 0.0000000000000020625 \quad \text{etc.}]\end{aligned}$$

$$= \frac{10}{7}\left\{1 - (.01005050633883\mathit{3125}\ldots)\right\}$$

$$= \frac{10}{7}\left\{\quad 0.98994949366116\mathit{6875}\ldots\right\}$$

therefore

$$\sqrt{2} = \quad 1.41421356237309\mathit{553}\ldots$$

and

$$\sqrt{\frac{1}{2}} = \frac{1}{2}\sqrt{2} = 0.70710678118654\mathit{7765}$$

For the first seven terms of the series the computation is very simple as illustrated above; beyond this point it begins to be more laborious. Using the first three terms of the series only, the computation can be made almost mentally, giving the result correct to seven places of decimal. Numerals in italics are inaccurate due to omission of terms of higher order.

$$\sqrt{2} = \frac{10}{7}(1 - 0.0100505)$$

$$= \frac{10}{7}(\quad 0.9899495)$$

$$= \quad 1.41421357$$

Even this is much more accurate than the requirement of the original problem.

METHOD 2—Approximating fraction; consider the following series of fractions:

$$\frac{1}{1} \qquad \frac{2}{3} \qquad \frac{5}{7}$$

$$\frac{12}{17} \qquad \frac{29}{41} \qquad \frac{70}{99}$$

$$\frac{169}{239} \qquad \frac{408}{577} \qquad \frac{985}{1393}$$

$$\frac{2378}{3363} \qquad \frac{5741}{8119} \qquad \frac{13860}{19601}$$

$$\frac{33461}{47321} \qquad \frac{80782}{114243} \qquad \frac{195025}{275807}$$

$$\frac{470832}{665857} \qquad \frac{1136689}{1607521} \qquad \frac{2744210}{3880899}$$

$$\frac{6625109}{9369319} \qquad \frac{1599428}{22619537} \qquad \frac{38613965}{54608393}$$

$$\frac{93222358}{131836323} \qquad \frac{225058681}{318281039} \qquad \frac{543339720}{768398401}$$

$$\frac{1311738121}{1855077841} \qquad \frac{3166815962}{4478554083} \qquad \frac{7645370045}{10812186007}$$

$$\frac{18457556052}{26102926097} \qquad \frac{44560482149}{63018038201} \qquad \frac{107578520350}{152139002499}$$

etc. etc. etc.

Each fraction of the above series represents the value of $\sqrt{1/2}$, and when inverted represents the value of $\sqrt{2}$, each subsequent fraction being a closer approximation than the one before. This is most easily verified by squaring any of the above fractions. For example, the squares of the first two rows are:

$$\frac{1}{1} \quad \frac{4}{9} \quad \frac{25}{49} \quad \frac{144}{289} \quad \frac{841}{1641} \quad \frac{4900}{9801}$$

These square fractions are all approximately equal to 1/2, the denominator being in each case equal to twice the numerator, ± 1. This rule applies to all the subsequent fractions.

Each fraction is obtained from the previous fraction by the following procedure:

1. Add the numerator and denominator of any fraction; this gives the numerator of the next fraction.
2. Add this numerator of the new fraction to the numerator of the previous fraction; this gives the denominator of the new fraction.

For example, starting with the fifth fraction (29/41), we get $29 + 41 = 70$, this is the numerator of the next fraction; $29 + 70 = 99$, this is the denominator of this new fraction; this makes the sixth fraction 70/99. For practical use it is not necessary to go beyond the twelfth fraction, which gives the values correct to the eighth place of decimal, *viz.*, $\sqrt{2} = 1.414213564$, and $\sqrt{1/2} = 0.707106782$.

To obtain the fractions of higher order, it is not necessary to go through all the intermediate fractions. If $m/n$ be the fraction of the $m$th order, the fraction of 2 $m$th order is, $2\,m\,n/(4\,m^2 + 1)$, if $m$ is an even figure. For example, the sixth fraction is 70/99; therefore, the twelfth fraction is $2 \times 70 \times 99/(4/70^2) + 1 = 13860/19601$; the twenty-fourth fraction is $2 \times 13860 \times 19601/(4.13860^2 + 1) = 543339720/768398401$; and so on.

The purpose of this letter is not merely to determine accurately the value of $\sqrt{2}$, but to introduce a new and interesting aspect of the theory of numbers. The series has many other interesting properties which need not be discussed in this letter.

Very truly yours,
S. L. GOKHALE (M'20)
General Engineering Lab.,
General Electric Co., Schenectady, N. Y.)

# Engineering Foundation

## Research Procedure Committee Appointed

With the approval and assistance of the Founder Societies, The Engineering Foundation has appointed a research procedure committee composed of one representative from each Founder Society selected from or designated by its main research committee annually, and nominated to the Foundation by its governing board or duly authorized officer, and two members of the Foundation Board.

The members appointed for the year 1932 are Thaddeus Merriman, representing the A.S.C.E., F. M. Becket, representing the A.I.M.E., W. H. Fulweiler, representing the A.S.M.E., L. W. Chubb, (F'21) representing the A.I.E.E., and E. DeGolyer and D. R. Yarnall, members of the Foundation board. The duties of this committee will be to aid the Foundation in ascertaining and meeting the research needs of its Founder societies and in making intelligent selections among the numerous projects in which the four societies are interested individually and collectively.

# Personal

## Honorary Membership Awarded Frank J. Sprague

On December 4, 1931, the board of directors elected Frank J. Sprague (A'87, F'12, past-president) an Honorary Member of the American Institute of Electrical Engineers. This is the highest grade of membership in the Institute and is held by only seven other Americans and three representatives of foreign countries.

Underwood & Underwood

F. J. SPRAGUE

The petition, previously presented to the board, is as follows:

"The undersigned Members and Fellows of the American Institute of Electrical Engineers propose for Honorary Membership, Dr. Frank J. Sprague, as the outstanding pioneer in the development of electric traction. We respectfully request the board to give the name of Dr. Sprague early consideration for this honor."

The following statement was also included with the petition:

"Dr. Sprague was not only the originator of the first successful electric traction, but had the same distinction in regard to the electric elevator. His invention of multiple unit train control was also a work of great importance."

Dr. Sprague has long been outstanding in the profession. He was born at Milford, Conn., July 25, 1857, and in 1878 graduated with honors from the U.S. Naval Academy. On his return in 1880 from a tour around the world as midshipman, he attempted to introduce electric light into the navy. He was ordered to the Crystal Palace Exposition, London, England, in 1882, as a member of the jury and in charge of tests on dynamo-electric machines, gas engines, and electric lights.

Dr. Sprague resigned from the navy in 1883 to take up electrical work, and was an assistant to Mr. Edison in the early development of the electric light. In 1884 he founded the Sprague Electric Railway and Motor Company, and pioneered in the development of electric motors and their application to industrial use. His pioneer work in electric traction followed and under his direction a trolley railway was built at Richmond, Va. in 1887 which well can be called the forerunner of the modern electric railway. Pioneer railway installations also were made in Italy and in Germany. These were followed by many similar systems throughout the world. Dr. Sprague also was active in the introduction of electric high speed and house automatic elevators, founding companies for the carrying on of this activity. In 1895 he invented the multiple-unit system of electric train control which now is so extensively used where two or more locomotive units are under common control. He has been an active advocate of underground rapid transit throughout the whole period of its development in New York City.

He is now president of the Sprague Development Corporation and the Sprague Safety Control and Signal Corporation; and is consulting engineer of the Westinghouse and General Electric companies. As consulting engineer for the Southern Pacific Company he made studies for the electrification of the Sierra-Nevada section of that system.

Dr. Sprague has long been active in Institute affairs, having served on various committees, as well as having been vice-president (1890-92) and president (1892-3). He was selected by both the Institute and the Inventors Guild as a member of the U.S. Naval Consulting Board, and engaged during the World War in the development of fuses, and air and depth bombs. He is also a member and past-president of the New York Electrical Society, the American Institute of Consulting Engineers, and the Inventors Guild; a member of the American Society of Civil Engineers, the New England Society, the New York Historical Society, Ye Old Settlers, the Institution of Electrical Engineers and Institution of Civil Engineers of England; an honorary member of the Franklin Institute and National Electric Light Association; and an associate member of the Society of Naval Architects and Marine Engineers. He was awarded the Gold Medal of the Paris Exposition (1889) for electric railway development; the Elliott Cresson Medal of the Franklin Institute (1904) for the multi-unit system; the Grand Prize for "invention and development in electric railways" at the St. Louis Exposition (1904); the Edison Gold Medal of the Institute "for meritorious achievement in electrical science, engineering and art" (1910); and the Franklin Medal (1921) "for fundamental inventions and achievements in electrical engineering." Dr. Sprague is a member of the University, Century, Bankers, and Railroad clubs.

EVERETT S. LEE (F'30) recently appointed by the General Electric Company, Schenectady, New York, to succeed L. T. Robinson (F'12, deceased) as engineer in charge of the general engineering laboratory, a position of significant responsibility, has served the profession in various representative capacities ever since his graduation from the University of Illinois in 1913. Immediately following graduation, he entered the G.E. test department. Later he went to Union College as an instructor in electrical engineering; his masters degree being awarded him there in 1915. During the war period he returned with a commission of first lieutenant to the University of Illinois as instructor in machine gunnery in its school of aeronautics. Upon his return to civilian duties, he was placed in charge of meters and instruments in the general engineering laboratory of the General Electric Company, later to be made assistant director, the position from which he arrived at his present promotion.

Mr. Lee has served the Institute diligently in the varying capacities of chairman of the A.I.E.E. Schenectady Section (1928-29); Sections committee (1929-32); meetings and papers committee (1927-30); instruments and measurements committee (1927-32, chairman 1927-30); coordination of Institute activities committee (1930-32); and upon the special committee on Institute policies (1931—). He is a member of Tau Beta Pi, Eta Kappa Nu, and Sigma Xi fraternities and also of various honorary engineering and scientific societies.

F. W. CLEMENTS (A'08) formerly state electricity commissioner of Victoria, Australia, has been appointed chairman of the state electricity commission to succeed the late Sir John Monash. Mr. Clements was born in Halstead, Essex, England in 1862, being educated in the public schools in London and also in Germany. His technical education was obtained at the City Guild College, London, supplemented by training at the Great Eastern Railway Works, and the Brush Company, both of London. Between 1881 and 1890 he was with the Brush Company in various capacities, including service as their representative in Hungary, and joint manager of their factory and contract department in Vienna. He later held positions in England, and in 1899 went to Australia being engineer and manager of the Electric Lighting and Traction Company of Australia, later local managing director and chief engineer of the Adelaide Electric Supply Company, South Australia. Mr. Clements later held responsible positions with other Australian companies prior to becoming state electricity commissioner. He is a member of the Institution of Electrical Engineers and the Australian Institute of Engineers.

E. S. LEE

G. C. WARD (M'24), for the last three years executive vice-president of the Southern California Edison Company, Ltd., Los Angeles, Calif., recently was elevated to the rank of senior vice-president of this company. Born in White Plains, N. Y., January 9, 1863, Doctor Ward was educated at Philips Academy, Andover, Mass., and between 1882 and 1902 was location and construction engineer for the following railroads: New York, West Shore and Buffalo; Erie; New York Central; Delaware and Hudson; and Mohawk and Malone. Between 1902 and 1911 he was associated with H. E. Huntington in the Pacific Electric and the Los Angeles railways. Following this he was president of the Pacific Light and Power Corporation, until that company was merged with the Southern California Edison Company in 1917. He then became vice-president in charge of construction and operation of the latter company, and continued in this position until being advanced to executive vice-president three years ago. Under Doctor Ward's generalship the well known engineering developments of his companies have been carried out, starting with the Big Creek plant and continuing through the completion of some 500,000 hp. in steam-electric generating capacity at Long Beach. The University of Southern California has honored him with the degree of doctor of engineering, and Oberlin College has conferred the degree of doctor of science upon him.

SIDNEY HOSMER (F'12) vice-president and L. L. EDGAR (A'12) vice-president, and assistant superintendent, of the Edison Electric Illuminating Company of Boston, Mass., have advanced to the respective offices of vice-president and assistant general manager, and vice-president in charge of the operating bureau; I. E. MOULTROP (F'29 and vice-president) the company's chief engineer, now has been appointed head of its construction bureau. All three of these men are well known as veterans in the utility's employ. Mr. Moultrop has served also as chairman of the Institute's Boston Section, as a member of the Boston Society of Civil Engineers, the National Electric Light Association, the American Standards Association, and vice-president of the American Engineering Council. He long has been a member of the A.S.M.E. power test and boiler code committees, and was on that society's Council three years as manager and two years as vice-president.

M. P. RICE (M'19) manager of publicity, General Electric Company, Schenectady, N. Y., retired as of December 31, 1931, leaving behind him a record of over 37 years of valuable service to the company. It was Mr. Rice himself who in 1903 established the General Electric Review, the company's technical magazine. Under his direction too, the Maqua Company, which produces much of the company's printed matter, was started. In 1921 when the company became interested in radio broadcasting, he was made director of the activity and in this position not only outlined the company's policy in this new field, but also established its three broadcasting stations at Schenectady, N. Y., Oakland, Calif., and Denver, Colo.

C. J. FECHHEIMER (F'14) previously of the power engineering department, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., has opened his own consulting engineering offices in the Title Guaranty Building, Milwaukee, Wis. Those interested in the development of electrical machinery will recall Mr. Fechheimer as the author of technical literature on this subject. At present he is extending his work in this field by giving a course of lectures on thermal problems in electrical machinery under the auspices of the Milwaukee Extension Division of the University of Wisconsin.

H. W. BIBBER (M'30) on January 1, 1932, left the central station engineering department of the General Electric Company, Schenectady, N. Y., to become associate professor of electrical engineering at Ohio State University. This is not Mr. Bibber's first teaching experience; he was instructor in electrical engineering at Massachusetts Institute of Technology following his return from studies in Ecole Superieure d'Electricite, Paris, and he is a member of the Society for the Promotion of Engineering Education.

W. S. Lee (A'04, F'13, past-president) of Charlotte, N. C., was elected president of the American Engineering Council at its annual meeting in Washington, D. C., January 14-16, 1932. Mr. Lee, who succeeds C. E. Grunsky of San Francisco, Calif., will hold office for two years. At this same meeting L. B. Stillwell (A'92, F'12, past-president) was chosen to continue as vice-president, and Farley Osgood (A'05, F'12, past-president) of New York, N. Y., was named treasurer.

Roy Page (M'21) vice-president and general manager of the Nebraska Power Company, Omaha, Neb., recently was chosen a vice-president of the Citizens' Power and Light Company of Council Bluffs, Iowa. Mr. Page is representative in professional circles in Omaha, having served as president of the Nebraska Section of the National Electric Light Association and also as chairman of the engineering section of the N.E.L.A. Middle West division.

J. M. Gaylord (M'13) formerly chief electrical engineer of the U.S. Bureau of Reclamation, and more recently superintendent of hydro generation for the Southern California Edison Company, Ltd., at Pasadena, Calif., now has been appointed chief electrical engineer of the Metropolitan Water District of Southern California. He has spent forty years on the Pacific Coast and is a widely recognized authority on electrical engineering in its relation to water power.

C. A. Leland, Jr., (M'27) vice-president and general manager of the Des Moines Electric Light Company, the Des Moines Gas Company and the Iowa Power and Light Company has been assigned to the charge of the Kansas utility properties of the North American Light and Power Company. He will retain his supervision of the Iowa holdings, and will operate for the Kansas utilities with his headquarters in Des Moines.

J. J. Smith (A'19) an electrical engineer of the General Electric Company, Schenectady, N. Y., has been appointed to succeed E. S. Lee as one of the assistant engineers of the general engineering laboratory. His association with the company dates from 1916 when he joined its switchboard test department in Schenectady, subsequently going to Pittsfield in the transformer engineering department and returning to Schenectady in 1919.

F. W. Tuck (A'16) formerly with the Pacific Gas and Electric Company as construction foreman and more recently superintendent of electric and line construction for the Anchorage Light and Power Company, now is electrical engineer in charge of construction and operation for Benguet Consolidated Mining Company and chief load despatcher for the North Luzon Power Company, both in the Philippine Islands.

J. M. Donaldson (A'04) chief engineer of the North Metropolitan Electric Power Supply Company, Northmet House, Cannon Hill, England, recently was elected president of the Institution of Electrical Engineers of Great Britain. As the result of earlier engineering work in the United States and Canada, Mr. Donaldson's worth as a professional man is recognized in this country as well as in England.

C. M. Brentlinger (M'27) formerly in the executive offices of the Western Union Telegraph Company, New York, N. Y., on December 1, 1931 was appointed division traffic superintendent for the company's central division comprising the states of Missouri, Kansas, Iowa, Nebraska, Minnesota, and North and South Dakota. His headquarters will be at Omaha, Neb.

E. W. Schilling (A'29) secretary-treasurer of the Iowa Section (1931-2) is now assistant professor of electrical engineering at the Michigan College of Mining and Technology. As instructor at Iowa State College, he completed his work for his degree of master of science, which he was awarded in 1930. He now is working toward his doctorate.

John Bankus (A'20) electrical engineer, Portland Electric Power Company, won the local section prize in the A.I.E.E. Portland Section at the annual meeting held Dec. 8, 1931. His paper portrayed a method of determining economic voltage and cable size for underground transmission.

S. Q. Hayes (F'12) an engineer of the Westinghouse Electric and Manufacturing Company, consulting engineer for the City of Quito, Ecuador, in 1928, and for the Quito Electric Light and Power Company in 1931, recently returned from Ecuador as its vice consul in Pittsburgh, Pa.

W. E. Thau (M'21) who has been director of marine engineering for Westinghouse Electric and Manufacturing Company, New York City, now has gone to the company's office at Lester, Pa. with the new title of manager of the marine general engineering division.

Otto Hartig (A'31) who has been serving as factory engineer for the Eagle Electric Manufacturing Company, Inc., Brooklyn, N. Y., now is occupied with emergency work for the hospital department, New York City, as mechanical draftsman.

A. N. Geyer (A'21) for several years has been associated with the Utah Power and Light Company of Salt Lake City, as maintenance engineer; now he has gone to Seattle, Washington, to identify himself with the Woodward Governor Company.

John Mann (A'31) designer of reactors and accessories and consultant on construction for the Metropolitan Device Corporation, Brooklyn, N. Y., now is electro-acoustical engineer in the Photo-electric Research Laboratory, Inc., New York, N. Y.

Kennard Moss (Student Member) a recent graduate of Texas Agricultural and Mechanical College is now in the employ of the Gulf Refining Company's engineering department, Port Arthur, Texas. His friends may reach him at 100 Lakeshore Drive, that city.

Harold Watkins (A'27) who has been in the electricity department of the Public Works Department, Freetown, Sierra Leone, West Africa, now has been made chief electrical engineer for the government of Sierra Leone, as announced late in December.

W. J. Walker (A'17) who has been serving the General Electric Company at Schenectady, N. Y. in railway supply and renewal parts sales, transportation department, now has been transferred to the company's works at Erie, Pa., in like capacity.

R. W. Sorensen (F'19) professor of electrical engineering at the California Institute of Technology, Pasadena, Calif., has been selected to serve on the board of directors for the Metropolitan Water District of Southern California.

C. V. Bullen (A'23) has left the electrical engineering department of the University of Oklahoma, Norman, Okla. and is now in the department of electrical engineering of the Texas Technological College, Lubbock, Texas.

Sidney Simpson (M'27) chief assistant electrical engineer for the North Western Railway, Lahore, Punjab, India, now is deputy locomotive superintendent (electrical) for the Eastern Bengal Railway, Kanchrapara, Bengal, India.

**G. B. Pulham** (M'27) for the last six years chief erecting engineer for the Metropolitan-Vickers Electrical Company, Ltd., in India, Burma, and Ceylon, leaves Calcutta February 1932 to return to England.

**C. H. Cutter** (A'28) district manager for the Pacific Electric Manufacturing Corporation at Seattle, Wash., has been appointed business manager for "R.P.M." the monthly paper of the Electric Club of Seattle.

**A. F. Grenell** (A'25) who for some time has been associated with the Bell Telephone Laboratories, Inc., New York, N. Y., now has gone to Honolulu on further engineering service for the laboratories.

**M. Yonezawa** (A'25) electrical engineer, Imperial Government Railways, Marunouchi, Tokyo, Japan, has been chosen as a lecturer at the Tokyo Technical University.

**C. W. Warner** (A'26) electrical engineer for the Florida Corporation at its Tallahassee office, recently was transferred to the company's St. Petersburg, Fla. office.

**E. W. Starr** (A'28) has removed from Elsmere, N. Y., to become instructor in electrical engineering at Cooper Union Institute of Technology, New York City.

**M. P. Colony** (A'23) assistant engineer of the Great Western Power Company, Sacramento, Calif., has joined the Pacific Gas and Electric Company, as estimator.

**Kern Dodge** (M'12) consulting engineer, Philadelphia, Pa., has been made director of public safety of Philadelphia.

# Obituary

**Lewis Starr Streng** (A'04-F'26) vice-president in charge of operation for the Louisville Gas and Electric Company, Louisville, Ky., died December 24, 1931, after an illness of several months. He was born in that city in 1876 and was graduated from Massachusetts Institute of Technology in 1898 with a bachelors degree in electrical engineering. That summer he went into the General Electric Company's test department at Schenectady, remaining there until December. Several times his technical work was interrupted by ill health, but in 1899 he entered the employ of the Peoples Light and Power Company, remaining with its successors, the United Electric Company of New Jersey and finally was promoted to inspector and assistant engineer. This latter office he held also with the Public Service Corporation of New Jersey. In 1906 he returned to his native state as chief engineer of the Kentucky Electric Company. For the Louisville Gas and Electric Company he was first chief engineer, then general superintendent before his later elevation to the vice-presidency. Two years ago Mr. Streng was placed in charge of purchases. Besides his membership in the Institute, he also belonged to The American Society of Mechanical Engineers, the American Gas Association, National Electric Light Association, Association of Edison Illuminating Companies, Engineers and Architects Club of Louisville, Electric Club, Standard Country Club and Quindecim Club.

L. S. STRENG

**Raymond Stanislous Masson** (A'99) widely known western consulting electrical engineer and former president of the Needles (Calif.) Gas and Electric Company, died at his home in Los Angeles, Calif., December 17, 1931. As consulting engineer for the Henry E. Huntington properties in southern and central California, Mr. Masson directed the construction of the first 40,000-volt transmission line in California, a line built in connection with the Borel hydroelectric plant of the Pacific Light and Power Corporation, a Huntington property which later became a part of the Southern California Edison system. Mr. Masson was born in Hammondsport, N. Y. in 1870, and did not retire from active business until 1929, when he was forced to do so because of ill health. He was graduated from Lehigh University with the class of 1892. From July 1892 to June 1893 he worked for the Field Engineering Company of New York on the Buffalo Railroad and several suburban roads; also on the construction of machinery and underground systems. The next year he joined the Westinghouse Electric and Manufacturing Company, spending 18 months in the shops at Pittsburgh, Pa., six months as switchboard operator at Niagara Falls Power Company, and two years in the San Francisco office as district engineer and salesman. He was at one time president and general manager of the Culiacan, Sinaloa, Mexico Electric Company.

**William Nesbit** (A'02-F'29) northeastern engineering manager of Westinghouse Electric and Manufacturing Company prior to his retirement two years ago, died December 31, 1931, after a lingering illness. He was born January 20, 1876; in 1895 became assistant electrician of the Central Foundry Company, Lewisburg, Pa. and during 1897-8 he engaged in an apprentice course at the Westinghouse company's main office in East Pittsburgh. The following year he was placed in charge of transformer testing. In 1900 he became transformer designer for the company, and during the interim between that time and 1926 when he took his position as northeastern manager, he was successively sales engineer at the Syracuse office of the Westinghouse company, sales engineer in its New York office, and manager of the company's engineering division in New York. To technical literature he contributed the book "Electrical Characteristics of Transmission Circuits," a work used extensively as a college text-book as well as being generally recognized as of valuable service to transmission engineers. Its compilation covered a period of fifteen years and it was in its fourth edition after the distribution of 12,000 copies in use.

**Bertram Philip Wilber** (A'03) assistant designing engineer, New York Edison Company, Irving Place, New York, N. Y., died at his home in Great Neck, N. Y., the latter part of December 1931. He was born in Philadelphia on the first of March 1871, educated in the public schools of Philadelphia and New York, and in the College of the City of New York, where he took a mechanical course. This he followed by an apprenticeship in the machine shops of the Pennsylvania Railroad Company. When he became interested in electricity much of his elementary study was self-imposed. From 1894 to 1905 was spent in the employ of the New York Edison Company as draftsman, designer, and chief draftsman in the design and construction of power and substations; from 1906 to 1916 he was assistant electrical engineer for L. B. Stillwell, in charge of the drafting office on the design and construction of power plants, factories, estimating, inspection, testing, etc. A year was spent with the Pratt Engineering and Machine Company in the construction of various chemical plants. He also served Westinghouse, Church, Kerr and Company as assistant engineer.

**William Bryan Duncan** (A'20) assistant professor of electrical engineering, Stanford University, Calif., died of pneumonia December 18, 1931. He was thirty-three years of age. Born at Fayetteville, Ark., his general technical education included one year at Stanford University prior to his employment by the San Joaquin Light and Power Company, Bakersfield, Calif. After several years of practical work with this company, he returned to Stanford and earned his bachelor's degree. Using summers and vacations for more work in practical fields, Professor Duncan continued at Stanford University, earning his E.E. degree and at the same time gaining valuable knowledge in actual experience of application. With a change of its teaching force, Stanford University made him instructor in electrical engineering and shortly thereafter advanced him to the assistant professorship. He has been a member of the faculty since 1927. He also had done considerable research in lightning protection for several large oil companies towards protective measures for Pacific Coast tank farms.

# Local Meetings

## Future Section Meetings

**Akron**

Feb. 9—At 4:00 p.m. inspection trip through the Ohio Edison Company's East Akron substation. At 7:45 p.m. movies: "Through Oil Lands." At 8:15 p.m. James H. Foote, Allied Engineers, Inc., will speak on Load Shifting Transformers at Salt Springs. Meeting to be held in the auditorium of the Ohio Edison Co.

March 8—Electrical Refrigeration and Air Conditioning, by W. M. Timmerman, Gen. Elec. Refrigeration Co. Movies. Meeting to be held at Ohio Pwr. Co., Canton, preceded by dinner at Elks Club.

**Baltimore**

Feb. 19—Some Features of Interest in Motor Driven Water Pumping Stations, by Leon Small, water engr., City of Baltimore.

March 18—Subject to be announced. Speaker: Captain Greenlee, Director of Naval Experimental Station.

**Chicago**

Feb. 10—Modern Underground Cable Practise, by Herman Halperin, Commonwealth Edison Co.

March 17—Coordination of Insulation, by F. E. Andrews, Pub. Serv. Co. of Northern Illinois.

**Cleveland**

Feb. 18—Lightning—Recent Investigations and Findings, by K. B. McEachron, Gen. Elec. Co., Schenectady, N. Y.

March 24—Joint meeting with Case School of Applied Science Branch. Speaker: Dr. Dayton C. Miller.

**Dallas**

Feb. 26—Speaker: Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co.

March 21—Underground Construction and Cable Developments, by John Oram, Dallas Pwr. & Lt. Co. Meeting to be held in Fort Worth, Texas.

**Detroit-Ann Arbor**

Feb. 16—Fundamental Physical and Psychological Aspects of Television, by J. O. Perrine, Am. Tel. & Tel. Co. Demonstrations. Meeting to be held in the auditorium of the Michigan Bell Tel. Co.

March 15—Vacuum Tubes and Their Application, by E. H. Vedder, Westinghouse Elec. & Mfg. Co.

**Lehigh Valley**

Feb. 12—Airplane and Ship to Shore Communication, by Lloyd Espenschied, Am. Tel. & Tel. Co. Meeting to be held in Chamber of Commerce Bldg., Scranton.

March 18—Research—Industry's Health Insurance, by S. M. Kintner, Westinghouse Elec. & Mfg. Co.

**Louisville**

Feb. 19—Lightning—Recent Investigations and Findings, by F. W. Peek, Jr., Gen. Elec. Co.

March 18—Men Who Have Made Electrical Engineering History. Meeting under the auspices of students at Univ. of Louisville. Demonstrations.

**Lynn**

Feb. 17—Ladies' night.

Feb. 24—Mercury Vapor Steam Cycle, by Messrs. Sheldon and Coulsen.

March 9—Miracles in Nature, by Doctor Pillsbury.

**New York**

Power Group, Feb. 18—A-C. Low-Voltage Networks, by C. W. Pickells, New York & Queens Elec. Lt. & Pwr. Co.; A. Pinto, Otis Elevator Co.; L. A. Nettleton, Brooklyn Edison Co. Meeting to be held at 7:30 p.m. in the auditorium, Pub. Serv. Elec. and Gas Co., 80 Park Place, Newark, N.J. Nominations for officers of the Power Group for the year 1932-33 will be received at this meeting.

**Pittsburgh**

Feb. 9—New Developments in Mercury Arc Rectifiers. Speaker from Westinghouse Elec. & Mfg. Co.

March 8—Joint meeting with Association of Iron & Steel Elec. Engrs., and Engineers' Society of Western Penn.

**Pittsfield**

Feb. 16—Man-Made Islands to Speed Ocean Flying, by E. R. Armstrong.

March—Competitive meeting with Schenectady Section.

March 1—Famous Women Spies and Their Methods, by Major Coulson.

**Seattle**

Feb.—Communication Meeting. Speaker to be provided by the Am. Tel. & Tel. Co. Joint meeting with Inst. of Radio Engrs.

March—Annual joint meeting of founder societies.

**Spokane**

Feb. 26—Speaker: Dean H. V. Carpenter, State College of Washington and vice-pres. A.I.E.E.

March 25—Joint meeting with the Student Branches of the State College of Washington and University of Idaho. Papers by local members and students.

**Vancouver**

March 7—Students' night.

## Past Section Meetings

**Baltimore**

Television—Its Physical, Fundamental, and Psychological Principles, by J. O. Perrine, Am. Tel. & Tel. Co. Demonstrations. Dinner meeting. Dec. 18. Att. 650.

**Boston**

Vertical Transportation, by A. S. Noyes, Otis Elevator Co. Illustrated. Films—"Virginia" and "Buried Sunshine." Dec. 8. Att. 65.

**Cleveland**

Behind the Scenes, by Zay Jeffries, Gen. Elec. Co. W. L. Enfield outlined developments in lamp construction. Inspection trip through the lamp development laboratory of the Gen. Elec. Co., moving pictures, and dinner. Dec. 17. Att. 173.

**Dallas**

Social meeting. Dec. 10. Att. 86.

**Denver**

Control of Commodity Prices, by M. F. Coolbaugh, Colorado School of Mines. Dinner. Dec. 18. Att. 20.

Precision Instruments, by A. W. Ainsworth, Wm. Ainsworth & Sons. Dinner. Nov. 20. Att. 53.

**Erie**

Electrons at Work and at Play, by Phillips Thomas, Westinghouse Elec. & Mfg. Co. Dec. 15. Att. 250.

**Florida**

Business meeting at which Prof. Melvin Price, chairman Florida State committee on engineers and employment organized by Amer. Engg. Council, spoke on the unemployment situation. Following this session the members took part in the Conference on Student Activities of District No. 4, and gave attention and discussion to many papers presented by students. Prizes were awarded to the authors of the three best papers. The activities were concluded with a banquet at the Hotel Thomas. Dec. 4. Att. 41.

Aims and Activities of the Institute and Electrical Industry in General, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Jan. 4. Att. 50.

**Fort Wayne**

A Method of Symmetrical Components, by C. S. Allen, Gen. Elec. Co.; Heaviside's Operational Calculus, by H. L. Boyer, Gen. Elec. Co. Dec. 17. Att. 32.

**Houston**

Arc Welding in Building Construction, by P. N. Vinther, Dallas Pwr. & Lt. Co. Dinner. Dec. 16. Att. 40.

**Indianapolis-Lafayette**

Some Aspects of the Control of Public Utilities, by Prof. L. M. Sears, Purdue Univ. Joint meeting with N.E.L.A. Dinner. Nov. 5. Att. 150.

Recent Developments in the Electrical Field, by C. W. Fick, Gen. Elec. Co. Illustrated. Dec. 18. Att. 50.

**Iowa**

Present and Future of the Electrical Industry, by H. B. Hoffhaus, Des Moines Elec. Lt. Co.; Transmission for Sale, by C. L. Sampson, Northwestern Bell Tel. Co. Dinner. Dec. 16. Att. 16.

**Kansas City**

Social gathering. Dec. 22. Att. 65.

**Los Angeles**

The Great Australian Bush, by E. T. Bailey, pres. International Adventures. Illustrated. Dinner. Dec. 8. Att. 143.

**Louisville**

The Engineers Place in the Sun, by Prof. W. E. Freeman, Univ. of Kentucky and vice-pres. A.I.E.E. Dec. 18. Att. 65.

**Lynn**

The Story of Lightning, by K. B. McEachron, Gen. Elec. Co. Illustrated. Dec. 16. Att. 350.

Milady Goes Exploring, by Mrs. Elizabeth Dickey. Dec. 2. Att. 1,200.

**Madison**

Joint meeting with the Univ. of Wisconsin Branch at which three papers on Faraday were presented by students. Dec. 10. Att. 53.

**Memphis**

Trackless Trolleys, by A. D. McWhorter, Memphis St. Railway Co. Dec. 8. Att. 35.

**Mexico**

Annual banquet. Nov. 28. Att. 52.

**Montana**

Illumination, by C. S. Bossler, Curtis Lighting Co. Refreshments. Dec. 3. Att. 63.

**New York**

Control of Vehicular Traffic, by R. E. Clisdell, Gen. Elec. Co., S. E. Kelley, Automatic Signal Engg. & Research Corp., and J. G. Hummel, Crouse Hinds Co. Jan. 6. Att. 200.

**Niagara Frontier**

Deion Principle Applied to Large Circuit Breakers and Other Applications, by C. H. Sanford, Westinghouse Elec. & Mfg. Co. Dec. 18. Att. 85.

**Oklahoma City**

Recent Views on Atomic Structure, by Homer L. Dodge, Univ. of Oklahoma. Moving pictures. Dec. 21. Att. 75.

**Philadelphia**

Social gathering. Dec. 14. Att. 250.

**Pittsburgh**

Recent Developments in Electrical Research, by Philips Thomas, Westinghouse Elec. & Mfg. Co. Demonstrations. Joint meeting with Engineers' Soc. of Western Penn. Dec. 8. Att. 160.

**Portland**

The Story of Aluminum, by C. R. Boyle, Aluminum Co. of America. Moving pictures. Nov. 17. Att. 80.

Determination of Economic Voltage and Cable Size for Underground Transmission, by John Bankus, Gen. Elec. Co.; Mechanical Strength of Wire Holders as Determined by Test, by Corbett McLean and M. C. Parker, Northwestern Elec. Co.; Latest Trend in Subway and Trench Lay Cable, by R. C. Schuknecht and T. W. Swartz, Northwestern Elec. Co.; A Special Application of the Potentiometer, by J. L. Watson and R. Gleeson, Gen. Elec. Co. John Bankus awarded $25.00 Section prize for presentation of the best paper. Joint meeting with Oregon State College Branch. Dec. 8. Att. 74.

**Providence**

Deion and Deion Grid Oil Circuit Breakers, by Theodore Braaten, Westinghouse Elec. & Mfg. Co. Dinner. Oct. 13. Att. 40.

Trolley Coaches and Electrically Operated Buses, by J. C. Thirlwall, Gen. Elec. Co. Dinner. Dec. 8. Att. 220.

**St. Louis**

The Osage Hydroelectric Project, by R. R. Wisner, Union Elec. Lt. & Pwr. Co. Film—"Lake of the Ozarks". Dec. 16. Att. 290.

**San Francisco**

California State Water Problem, by Lester S. Ready, consulting engr. Dec. 4. Att. 73.

**Seattle**

Symposium on Rural Electrification, by H. J. Gille, Puget Sound Pwr. & Lt. Co., and L. J. Smith, Secy. State Committee on Relation of Electricity to Agriculture. Dinner. Dec. 15. Att. 66.

**Sharon**

Television—Its Psychological Effects, by J. O. Perrine, Am. Tel. & Tel. Co. Dec. 22. Att. 200.

**Spokane**

Manufacture of Sawdust Briquets, by R. T. Bowling, Potlatch Forests Inc. Dec. 16. Att. 25.

**Syracuse**

Radio—The Giant New Industry, by J. D. Kelly, Westinghouse Elec. & Mfg. Co. Jan. 4. Att. 203.

**Toledo**

Television—Its Fundamental, Physical, and Psychological Principles, by J. O. Perrine, Am. Tel. & Tel. Co. Dec. 10. Att. 800.

**Toronto**

Vibration and Fatigue in Electrical Conductors, by A. E. Davison, J. A. Ingles, and V. M. Martinoff, Hydroelectric Pwr. Comm. of Ontario. Dec. 11. Att. 100.

The Apparent Failure of Democracy, by A. T. DeLury, University College. Joint meeting with Engg. Inst. of Canada. Jan. 8. Att. 250.

**Utah**

Airway Lighting, by Alvin Priel, Dept. of Commerce. Nov. 9. Att. 38.

Elwood Bachman, Gen. Elec. Co., described the electrical installation at the Film Flom Mine of the Hudson Bay Mining and Smelting Co. Dinner. Dec. 14. Att. 32.

**Vancouver**

The Design of the Modern Radio Receiver, by V. W. M. Fouracre, Northern Elec. Co. Dec. 7. Att. 55.

**Washington**

International Comparison of Electrical Standards, by C. W. Vinal, and The International Illuminating Congress of 1931, by E. C. Crittenden, both of Bureau of Standards. Dinner. Dec. 8. Att. 75.

**Worcester**

Adventures in Science, by E. L. Manning, Gen. Elec. Co. Joint meeting with engineering societies in Worcester. Dec. 9. Att. 1,000.

## Past Branch Meetings

**University of Akron**

The Progress of Radio, by John Chenot, student; Refrigeration, by R. Gerber, student. Dec. 9. Att. 15.

**Alabama Polytechnic Institute**

General discussion. Dec. 2. Att. 8.

Machines, by Prof. A. Thomas. T. N. Pyke, student, outlined his experiences at the Conference on Student Activities of District No. 4, held at the Univ. of Florida. Dec. 10. Att. 29.

**University of Arkansas**

Railway Signals, by F. S. Raedels, student; Potentiometers, by M. N. Shofner, student; Use of Library and Technical Journals, by W. J. Pruett, student. Dec. 16. Att. 30.

Standardization Rules, by H. L. Scott, student; Standardization Laboratory, by C. M. Huggler, student; Electrical Standards, by P. H. Johnson, student. Jan. 6. Att. 32.

**Case School of Applied Science**

Lectures and demonstrations on lighting. Dec. 17. Att. 30.

**Catholic University of America**

Transatlantic Cable Laying, by Prof. T. J. McKavanagh, counselor. Illustrated. Dec. 9. Att. 38.

**University of Cincinnati**

Operating Experience with Low Voltage A-C. Networks, by L. L. Bosch, Columbia Engg. & Mgt. Corp. Dec. 9. Att. 40.

**Clemson Agricultural College**

A Mooring Mast on Wheels, by E. C. Parker, student. M. M. Smith, student, outlined current events in the electrical industry. Dec. 10. Att. 33.

Thomas A. Edison, by C. P. Walker, student. Moving pictures. Jan. 7. Att. 30.

**Colorado State Agricultural College**

Organization of Doherty Cadet System of Public Service Co. of Colorado, by Thomas Gray, Public Service Co. of Colo. Dec. 7. Att. 17.

Application of Electrical Heat in Annealing, by John Kay, student. Dec. 14. Att. 18.

**Cooper Union**

The Wilkins Expedition to Polar Regions, by John A. Lundbeck, member of the electrical crew of the submarine "Nautilus." Dec. 11. Att. 65.

**Cornell University**

The Present Economic Situation, by Dean D. S. Kimball. Joint meeting with Ithaca Section. Dec. 11. Att. 52.

**University of Detroit**

Substation Operation, by Francis Moran, student; Radio Receiving Tubes, by Louis McNabb, student. Films—"Audion" and "That Little Big Fellow." Dec. 10. Att. 28.

**University of Florida**

Some Institute Problems, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Jan. 5. Att. 165.

**Georgia School of Technology**

Residence Lighting and Eye Conservation, by H. M. Horton, Gen. Elec. Co. Illustrated. Dec. 8. Att. 55.

**Harvard University**

History and Recent Development of the Kennelly-Heaviside Layer, by H. R. Mimno; Television, by J. H. Wright, student. Dec. 9. Att. 33.

**University of Illinois**

Film—"Blasting the Waterways of America." Dec. 9. Att. 25.

Transformer and Rectifier Connections, by Dean A. S. Langsdorf, Washington Univ. Dec. 17. Att. 160.

**Iowa State College**

Election of officers as follows: E. K. Rohr, chairman; M. D. Buttolph, vice-chairman; A. F. Zissler, secy.; F. G. Holdcroft, treas. Dec. 10. Att. 40.

**University of Kansas**

Klydonograph, by J. D. Swofford, student. Dec. 10. Att. 30.

Election of officers as follows: Wm. Kyte, chairman; Louis Farber, vice-chairman; Max Brauninger, secy.; Glen Wakely, treas. Moving pictures. Jan. 7. Att. 47.

**University of Kentucky**

Short Wave Transmission, by J. C. Starks, student. Dec. 17. Att. 39.

**Lewis Institute**

What Goes on in a Power House, by A. L. Peterson, Commonwealth Edison Co. Dec. 4. Att. 125.

**University of Louisville**

General discussion. Dec. 18. Att. 21.

**Marquette University**

The Electrical Profession, Development, and Organization of the A.I.E.E., by C. H. Krueger, chairman, Milwaukee Sec. Oct. 8. Att. 25.

**Massachusetts Institute of Technology**

Opportunities of the Young Electrical Engineering Graduate in a Large Manufacturing Company, by E. O. Shreve, Gen. Elec. Co. Dinner and smoker followed. Dec. 15. Att. 250.

**University of Michigan**

Commercial Aspects of a Public Utility, by A. D. McLay, Detroit Edison Co. Dec. 8. Att. 62.

**School of Engineering of Milwaukee**

The History of the A.I.E.E., by Taylor Decker and H. R. Spike, students. Film—"The Single Ridge." Dec. 10. Att. 37.

**University of Minnesota**

Inspection trip through the Pillsbury flour mills. Nov. 13. Att. 75.

Life of Faraday, by Edward Loye, student. Dec. 8. Att. 13.

**Mississippi A. & M. College**

The Life of Thomas A. Edison, by C. R. Lillybridge, student. Illustrated. Dec. 8. Att. 30.

**Missouri School of Mines and Metallurgy**

Prof. I. H. Lovett, counselor, and W. O. Woods, chairman, discussed electrification of railways. Rex Horn, student, described the uses of mercury arc rectifiers in electric railways. Dec. 9. Att. 11.

**Montana State College**

Ten papers presented by students. Dec. 3. Att. 119.

Illumination, by E. Bossler, Curtis Lighting Co. Joint meeting with Montana Section. Dec. 3. Att. 34.

Six papers presented by students. Dec. 10. Att. 114.

**University of Nebraska**

The Photoelectric Cell, by P. Jorgeson, student; The Potash Industry of Western Nebraska, by E. Knight, student. Dec. 9. Att. 16.

**University of Nevada**

Brushes and Commutation, by E. Zeigler, Westinghouse Elec. & Mfg. Co. Nov. 18. Att. 22.

**Newark College of Engineering**

Electrical Engineering Experiences in Brazil, by W. V. VanDyck, International Gen. Elec. Co. Dec. 16. Att. 35.

Life of Thomas A. Edison, by Prof. J. C. Peet, counselor. Jan. 4. Att. 14.

**University of New Hampshire**

Motion pictures. Nov. 28. Att. 31.

The Cold Cathode One-Hundred and Ten Volt Gaseous Illumina, by C. C. Dolloff, student. Dec. 5. Att. 30.

**University of New Mexico**

Smoker. Film—"Dynamic America." Dec. 9. Att. 35.

V. Brown, student, described his experiences while employed by the Westinghouse Elec. & Mfg. Co. Dec. 16. Att. 9.

**College of the City of New York**

Informal dance. Nov. 19. Att. 48.

The Life of Faraday and His Contributions to Science, by I. E. Lawlor, student; Faraday and Henry, by J. Raggazzini, student. Dec. 17. Att. 35.

**New York University**

Noise in Machinery, by H. C. Fleming, student; The Use of Photoelectric Cells in Photometry, by E. H. Osterland, student. Nov. 17. Att. 14.

Interurban Railway Transportation, by J. P. Monroe, student; Electron Tubes, by L. E. Dinnar, student. Dec. 1. Att. 15.

**North Carolina State College**

Banquet. Nov. 23. Att. 48.

Home Lighting, by J. C. McKinney, student; Prof. R. S. Fouraker, counselor, and G. E. Ritchie, chairman, gave reports of the activities at the Conference on Student Activities of District No. 4, held at the University of Florida. Dec. 8. Att. 28.

**University of North Dakota**

Relative to Relativity, by Prof. C. W. Byers. Dec. 9. Att. 26.

**Northeastern University**

Cables, Their Construction and Use, by E. W. Davis, Simplex Wire & Cable Co. Refreshments. Dec. 4. Att. 42.

**Ohio University**

Film—"Buried Sunshine." Jan. 6. Att. 36.

**Oklahoma A. & M. College**

Talks by several students. Nov. 23. Att. 25.

The Development, Theory, and Application of Watt-Hour Meters, by Harold Brown, student. Dec. 7. Att. 30.

**Oregon State College**

Joint meeting with the Portland Section. (See report under "Past Section Meetings.") Dec. 8. Att. 82.

**Pennsylvania State College**

Railway Signaling Devices and Their Application, by Mr. Rice; The Sonotone and Its Fundamental Construction, by Mr. Holt. Dec. 9. Att. 46.

**Pratt Institute**

Film—"The Story of an Electric Meter." Dec. 21. Att. 24.

**Rensselaer Polytechnic Institute**

A-C. Networks, by D. K. Blake, Gen. Elec. Co. Dec. 8. Att. 100.

**Rhode Island State College**

Film—"The Electric Ship." Dec. 3. Att. 30.

Action of the "Noden Valve" Rectifier, by M. J. Carr, student; The Common "Tungar" Rectifier, by Joseph Strauss and George Freedman, students. Dec. 10. Att. 18.

Inspection trips through the Industrial Trust Building and the Narragansett Elec. Lt. Co., followed by a lecture on Television, by J. O. Perrine, Am. Tel. & Tel. Co. Dec. 15. Att. 18.

Mercury Arc Rectifiers, by J. F. Schmidt, student. Dec. 17. Att. 10.

**Rice Institute**

Discussion. Jan. 6. Att. 11.

**Rose Polytechnic Institute**

Thomas A. Edison, by Wayne Plimmer, student. Dec. 9. Att. 38.

**University of Santa Clara**

Film—"Thomas A. Edison." Joint meeting with A.S.M.E. Dec. 10. Att. 89.

**University of South Carolina**

Election of officers as follows: A. R. Urquhart, chairman; H. G. Smith, vice-chairman; E. C. Salley, secy.-treas. Dec. 10. Att. 31.

**South Dakota State School of Mines**

General discussion. Dec. 3. Att. 30.

**University of Southern California**

Ship to Shore Communication, by Paul Johnson, Pacific Tel. & Tel. Co. Dec. 2. Att. 26.

Applications of Thyratron Tubes, by Berdett Ives, Gen. Elec. Co. Dec. 9. Att. 23.

**Southern Methodist University**

Life Works of Thomas A. Edison, by A. Fellrath, student. Illustrated. Joint meeting with A.S.M.E. Branch. Oct. 9. Att. 32.

**Stanford University**

Inspection trip through Pacific Gas & Elec. Co. Station A. Oct. 24. Att. 22.

Photo-Telegraphy Equipment, by W. Noel Eldred, student. Dec. 3. Att. 21.

Inspection trip through an exchange of Pacific Tel. & Tel. Co., San Francisco. Dec. 4. Att. 23.

**Stevens Institute of Technology**

Talk by Col. C. O. Gunther on the Reserve Officers Training Corps. Dec. 11. Att. 38.

Inspection trip through the U.S.S. Akron and U.S.S. Los Angeles. Nov. 27. Att. 30.

**University of Tennessee**

The Life of Thomas A. Edison, by C. J. Bryn, student. Illustrated. Nov. 25. Att. 65.

**Texas A. & M. College**

General discussion of Branch activities. Dec. 7. Att. 20.

Business meeting. Jan. 7. Att. 25.

**Texas Technological College**

Talks by Prof. L. S. Grandy and Dean Wm. J. Miller on the activities of the A.I.E.E. Film—"Magic of Communications." Nov. 23. Att. 27.

**University of Texas**

H. P. Woods, student, described a new proposed method of solving constants of the Fourier series by means of electromechanical mechanisms. Oct. 22. Att. 12.

**University of Utah**

Sunlight Lamps, by W. Ottenstein, student; Mercury Arc Lamps, by E. I. Christensen, student. Dec. 3. Att. 27.

You, by H. T. Plumb, Gen. Elec. Co. Dec. 10. Att. 55.

**University of Vermont**

Radio Interference, by Mr. Logan, student. Nov. 23. Att. 18.

Film—"The Single Ridge." Dec. 7. Att. 33.

**Virginia Military Institute**

Electrical Refrigeration, by R. J. Meybin, student; "DeForest—The Man Who Made Radio Broadcasting Possible," by J. Roberts, student; An Automatic Diesel Electric Plant, by H. J. Pence, student; The Radio Telephone, by T. J. Moore, student. Dec. 5. Att. 55.

WABC's New Wireless Antenna, by R. P. Sledge, student; Sound Pictures, by C. E. Schoonover, student; The Niagara Power Development, by S. J. Stone, student; A Power Plant That Flies, by G. B. Hightower, student; The Restoration of the Beauty of Niagara, by S. J. Mergenhagen, student. Dec. 22. Att. 54.

The Communication System of the Waldorf-Astoria, by W. L. Kelly, student; The Effects of Electric Shock, by C. S. Betts, student; Neon Electric Signs, by C. A. Payne, student; The Work of the Army Air Corps, by W. P. DeSaussure, student. Jan. 4. Att. 57.

**Virginia Polytechnic Institute**

Reports of the Conference on Student Activities of District No. 4, held at the Univ. of Florida were given by those who attended that meeting. Dec. 10. Att. 36.

**State College of Washington**

Films—"Industrious Diamonds," "The Telephone," and "Voice Highways." Dec. 4. Att. 37.

**Washington University**

Operation of the St. Louis Municipal Police Radio Broadcasting System, by Louis Siech, student. Dec. 11. Att. 17.

**University of Wyoming**

Film—"The Single Ridge." Nov. 20. Att. 21.

The Development of the Microphone, by F. Wickenkamp, student; Electrical Aids to Blind Flying, by T. R. Hance, student. Dec. 1. Att. 6.

**Yale University**

Acoustics, by S. K. Wolfe. Dec. 8. Att. 44.

# Employment Notes

## Of the Engineering Societies Employment Service

## Men Available

### Construction

E.E., 33, 10 yr. practical experience in elect. construction work on new buildings. Familiar with all branches of elect. contracting including estimating, field engg. and purchasing. Has had complete charge of electrical work in various large building projects in New York City. A-850.

ASSOC. E.E., 34, married, technical education, desires position with utility. Exceptional ability in underground transmission and distribution systems. One yr. central station construction experience. Location, immaterial. Available on short notice. D-278.

### Design and Development

E.E. and M.E. grad., 37. 13 yr. comprehensive experience with nationally known firms in designing, drafting, and engineering of modern power plants and substations. Engg. reports and specifications for diesel-electric plants. Inspection and experimental work. Foreign languages. Work and location immaterial. Available immediately. C-8195.

E.E., M.E. DESIGN ENGR. College trained, wide experience development and design; mech. and elec. apparatus; special machinery; thorough knowledge manufacturing; 5 patents. Desires connection where inventive ability and persevering effort to obtain desired results efficiently and economically are essential. Excellent references. N.Y. metropolitan district preferred. B-8219.

PWR. PLANT ENGR. 15 yr. exp. in drafting, design, and construction; elec. and mech., including complete mill and pwr. plant steam generating equipment. English schooling and technical training. American citizen, single. Also some operating and maintenance experience. B-9747.

E.E., grad. 32, married. 8 yr. exp. elec. and mech. design of small motors and fans. Capable of full responsibility for development of a-c. and d-c. motors, generators, and allied products. Up to the minute on capacitor motor design. Middlewest preferred. C-5353.

M.E. and E.E., FORMER CORNELL INSTRUCTOR in machine design for 4 yr., Allis-Chalmers designers and checker 5 yr., served shop apprenticeship, 32, single. Desires teaching or engg. opportunity. Salary open. D-122.

GRAD. E. E., single, 29, Westinghouse engg. and design school graduate course. Five yr. transformer design experience. Desires position with utility, engg. or mfg. concern. D-209.

### Draftsmen

ELEC. DRAFTSMAN, 44, married, 5 yr. experience switchboard, supervisory control wiring diagrams, plant and substation layout. 2,300-volt and 220-kv. distribution system. Available at once. Location, anywhere. D-209.

E. E. GRAD., 1928, single, 27. Experienced in design drafting, estimating and layout of substations, switchboards, wiring diagrams, lighting, conduit, transmission and distribution lines. Desires connection in elec. field. Location, immaterial. D-89.

### Executives

GRAD. ELEC., HYDRO-ELEC. ENGR., 31, married. 2 yr. exp. marine elec. installation. 7 yr. exp. design, construction of steam and hydro pwr. plants, outdoor and indoor substations, transm. and distr. lines, wiring diag., indus. plants, office blds., estimating, preparation of specifications. Desires position where experience counts. Available short notice. Middle Atlantic States preferred. D-212.

ENGG. EXEC., 33, married. Elec. grad., 10 yr. exp. in mgmt., design and constr. with leading utility company and mfgr. Desires position with utility company, mfgr., or consultant where initiative, aggressiveness, and judiciousness will show in results of work. South or West preferred. Available immediately. C-4734.

EXEC., SALES, PURCHASING or as asst. to engr. Grad. engr., 20 yr. exp. in maintenance, contracting, purchasing, and design and layout of mech. and elec. eqpt. of indust. and pwr. plants. Location, N.Y. metropolitan district. B-5050.

E.E. GRAD. Married. 15 yr. with electrification, distribution, generation, substations, motor applications and controls, lighting, etc. as applied to utilities, coal mining, cement mills, elec. furnaces, automotive industries. Experience covers estimates, design, layouts, constr. and maintenance. Utility, mining, or indus. concern desired. C-5277.

EXEC. ASST. to pres. or v.-pres. of holding company or large operating utility. 24 yr. exp. in all phases of operation, production, transmission, distribution, utilization, engineering, and construction of utilities and industrials; also rates and valuations, elec., gas and water systems. D-208.

E.E. Wide indus. background in exec. capacities: elec. and mech. engg., steel industry; devpt. engg., mining industries; comml. and pwr. sales engg., utility field; technical editor in publishing field; versed in economics and mgmt. and able to cooperate with personnel. Available immediately. Location immaterial. B-4905.

E.E., GRAD. 14 yr. exp. with utilities and engg. firms covering engg., design, and valuation of pwr. plants, substations and transm. lines. Desires position with utility or engg. firm where organizing and exec., as well as engg. ability is required. Available immediately. C-9570.

ENGG. EXECUTIVE, 33, E.E. and M.E. Grad., ten yr. experience in mgmt., design, construction, production, accounting, and sales, with steel mill, mfr., and utility desires position as chief engr., works mgr., or other executive capacity where a calm, judicial disposition coupled with initiative and aggressiveness will show up in results. C-1297.

E.E. Grad., 48, married. Twenty-six yr. experience as designing, report, power and executive engineer with 3 engg. and construction firms, including system planning, design, construction cost estimating and construction supervision of power plants, substations and transmission facilities for utilities and industrials, Studies of operating economics. B-4553.

E.E. Grad. R.P.I., 34, married. Five yr. with large mfr. of elec. control equipment. Five yr. with prominent engg. firm as elec. designer on power plant and industrial work. Familiar with physical layout, elec. equipment, and wiring for central stations and industrial plants. B-6274.

E. E. GRAD., 1910, experience principally in power and light elect. engg., desires position offering similar or elec. ry. experience. Eastern location preferred. B-1923.

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco
N. D. Cook, Manager

205 West Wacker Drive
Chicago
L. E. Griffith, Manager

31 West 39th St.
New York
W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

E. E., 30, 8 yr. broad utility experience, desires new association. Executive ability, ambitious and seriously seeking opportunity where progress can be expected in exchange for effort. Background of practical and administrative detail in power distribution plants. Keenly interested in rural electrification, coordinated commercial technical problems. Middlewest preferred, not essential. C-9959.

EXECUTIVE ENGR., 54, widower, gen. mgr., small utility. Asst. mgr., dist. mgr. of larger organization. Over 20 yr. executive experience in operation of small town utilities. Also qualified as valuation and rate engr. Available immediately. Location preferred, U.S.A. or Canada. B-7932-321-C-1-San Francisco.

**Financial**

FINANCIAL ENGR., Cornell (M.E.-E.E.). Twelve yr. regulatory commission; 4 with utility holding mgmt. corp.; 8 months intensive course bond buying department leading insurance company; employed almost 4 yr. thereafter on financial and fact finding investigations by outstanding consulting engg. organization. Desires opportunity New York City. Salary open. C-2953.

**Instruction**

UNIV. OF WASHINGTON GRAD., E.E., 2 yr. with Bell Tel. Lab., 5 yr. teaching elec. and mech. engg., and 2 yr. testing and experimental work with bus and truck manufacturer. Desires position with automobile or truck manufacturer, or teaching automotive engg. Available at once. B-7830.

E.E. Grad., 21, single, B.S., 1931, Worcester Polytechnic Inst. desires connection with industry, or with teaching; also interested in drafting. Location, immaterial. Available upon short notice. D-228.

E. E. GRAD., member Tau Beta Pi, Assoc. A.I.E.E., degrees B.S., will teach mathematics, power plant design, or structural design. B-5551.

**Maintenance and Operation**

E.E., 32, married, 12 yr. experience in the construction, maintenance and operation of power house auxiliaries, high voltage switching equipment. Substations, switchboard erection and wiring, control wiring and relay applications. Location, immaterial. Available at once. D-273.

E.E. Grad. 33 years, wide experience in operation and maintenance of both steam and hydro power plants and system operation. Also well educated in modern business and 5 yr. experience in accounting. Excellent references. Will accept position anywhere in U.S. C-7796.

E.E., 29, married. Westinghouse and Western Electric training. Five yr. maintenance and construction, 2 yr. power plant construction and 2 yr. detailing and layout. Desires position with mfg., engg. utility or ry. concern. Location, immaterial. Available on short notice. D-257.

CONSTRUCTION AND MAINTENANCE SUPT., E.E. Grad., 37, married. Thirteen yr. experience in the utility field, particularly in engg., construction and maintenance of distribution and transmission substations. Desires position wish large utility with responsibility for the construction, operation and maintenance of substations. B-2885.

**Research**

1931 E.E. GRAD., 23, single. Desires position with any mfg., utility, concern, or in any elec. engg. field. Prefers position in design and research, or the application and use of vacuum tubes. Willing to start at the bottom. Location, immaterial. Available immediately. D-221.

M.I.T. GRAD. E.E., 35, married. Six yr. industrial and teaching experience in e.e. Several years private research and development work on own initiative. Good ability, integrity, and personality. Desires position for life work. Location preferred, Middlewest or South. C-2826.

PHYSICIST, 32, married, 12 yr. experience in laboratories, large elec. mfrs., desires development engg. with small company. Experience mostly with vacuum or gas discharge devices, good theoretical knowledge of high frequency currents (Harvard graduate); physical chemistry, particularly thermodynamics, theoretical mechanics, and probability theory. B-8390.

**Sales**

COMMERCIAL MGR., 40, married. Grad. E.E. Fifteen yr. elec. pwr. companies in charge of sale of industrial power and equipment. Handled domestic sales. Trained salesmen. Large results. Previous 8 yr. handled men high tension hydroelectric construction and operation. Will consider any location. D-250-3112-C-2-San Francisco.

E. E., Cornell Unv. 1925, G.E. test course and 4 yr. sales engr. with Gen. Elec. Co. Desires position with industrial concern, consulting engg. firm or utility. Southern location preferred but interested in any locality where there is opportunity. Available on short notice. C-7135.

DISTRICT SALES MGR. OR MFR'S AGENT. Experienced engg. representative, desires connection with high grade company that has line of industrial or utility equipment. East preferred. B-4067.

E.E. GRAD., married, 39, wide sales experience with utility and industrial companies on electrical supplies, merchandise, and equipment. Desires position requiring good personality and ability to meet executives as well as a thorough knowledge of selling and of merchandising. B-1196.

**Testing**

1930 E.E., Drexel Inst., 24, single, 1½ yr. experience in making complete electrical tests on distribution, power and rectifier transformers, and metering equipment. Also G.E. test floor experience. Desires position with utility or industrial concern. Available at once. Location, immaterial. C-9913.

**Junior Engineers**

1931 GRAD. E.E., of 5 yr. co-op. school, 23, single. Experience includes machine shop, telephone central office trouble shooting, and large municipal fire alarm system. Desires position with mfr. or utility. Willing to start at bottom. Middlewest preferred; elsewhere satisfactory. C-9825.

1931 E.E. GRAD., Midwestern college, 24, single. One yr. student engr. on G.E. test. References furnished. Available on 2 wk. notice. C-9497.

GRAD. E.E., 1929, single, 23. Fifteen months as student engr. on G.E. test. Some test, drafting, and switchboard construction experience before graduation. Interested in position with concern doing consulting or construction work or with utility or mfr. Available at once. Location anywhere in U.S. C-8028.

1931 GRAD. E.E., single, 22, American. Desires position in the elect. industry with an opportunity for advancement. Chicago resident, location preferred, Middlewest. Available immediately. C-9909.

1931 E.E. Grad., 24, single. Experience in maintenance and installation of power plant equipment, also knowledge of photoelectric cells and pub. address systems. Available immediately. D-289.

1931 E.E. Grad., 24, American, single, Univ. of Virginia, desires position in elect. industry, preferably radio or one of its affiliated branches. Experience in protective relay systems with utility. Has kept up with radio industry since 1920. Salary secondary. Location, U.S. or foreign. D-290.

JUNIOR ENGR., 26, single. Desires connection with utility, sound picture industry or radio mfg. firm. G.E. test course, utility distribution test experience. Test, design, construction, maintenance and engg. work in radio receiver mfg. plant. Location, immaterial. C-8596.

1931 E.E. GRAD., Midwest univ., 23, single. Three months' experience with large utility, 3 months with elect. contacting and construction company. Desires utility work, especially interested in power plants, transmission, distribution, agricultural development. Location, immaterial. D-282.

GRAD. E.E., 27, married, 5 yr. experience with Gen. Elec. Co., including test course, induction motor design, application engg., and district office sales work. Also experience in automotive electrical work. Available on short notice. C-9236.

E. E. GRAD., 22, single. Experienced in power transformer repairing, overhead and underground systems maintenance for pub. utility. Some experience in electric refrigeration and ice cream manufacturing. Specialized in transmission in college. Will consider any job within reason. Location, anywhere. Available at once. C-9418.

E. E., Pratt 1931. Experience in vacuum tubes, resistors, technical and general office work. Desires employment in radio, television, or sound work. Location, New York. Available immediately. C-5636.

1931 E. E. GRAD., Lehigh Univ., 22, single. Summer experience with utility. Interested in position with utility or industrial concern. Eastern states preferred, but other locations considered. Available at once. D-301.

1931 GRAD. E. E., 23, single. B.S. degree from Montana State College. Special courses taken in utility work. Excellent scholastic record. Location, immaterial, foreign western or otherwise. Experience desirable. Available immediately. D-303.

# Membership

## Recommended for Transfer

The board of examiners, at its meetings on the dates indicated below recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the national secretary.

### To Grade of Fellow (Jan. 20, 1932)

Foote, James H., supervising elec. engr., Commonwealth & Southern Corp., Jackson, Mich.

Kloeffler, Royce G., prof. of elec. engg. and head of dept., Kansas State Col., Manhattan.

### To Grade of Member (Dec. 22, 1931)

Cornelius, Clinton C., supt., overhead systems engg. dept., Kansas City Pwr. & Lt. Co., Kansas City, Mo.

Fitz, Ernest S., mgr., prod. & trans., Virginia Elec. & Pwr. Co., Richmond, Va.

Hall, Raymond A., district plant engr., Pacific Tel. & Tel. Co., San Francisco, Calif.

Hollister, Vernon L., consulting engr., prof. elec. engg., Univ. of Nebraska, Lincoln.

Hotopp, Alfred H., Jr., divn. engr., Wired Radio, Inc., Ampere, N.J.

Kalantar, H. Hamaz, elec. engr., New York, N.Y.

Loud, Francis M., engr., Jackson & Moreland, New York, N.Y.

Maxwell, John F., head of distribution divn. E.E. dept., Edison Elec. Illum. Co., Boston, Mass.

McCarty, Roy A., mgr., pwr. engg. dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Mowdawalla, Framroze N., exec. engr., Hydro Elec. Dept., Chepauk, Madras, India

Newton, Edward T., patent examiner, U.S. Pat. Off., Washington, D.C.

Peek, Joseph W., elec. engr., Cleveland Elec. Illum. Co., Cleveland, O.

Wolff, Samuel S., chf. engr., American Elec. Motor Co., Cedarbury, Wis.

### To Grade of Member (Jan. 20, 1932)

Doremus, Francis H., sales engr., Gen. Elec. Co. Denver, Colo.

Ewart, James B., chief engr., The Teleregister Corp., New York

Graff, Murray G., sales engr., Gen. Elec. Co., Denver, Colo.

Halloran, Delavan, asst. engr., N.Y. & Queens Elec. Lt. & Pwr. Co., Flushing, N.Y.

Harte, Charles R., engr., The Connecticut Co., New Haven, Conn.

Kidd, Walter J., design engr., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

Knutz, Wm. H., engr. of elec. design, Midland United Co., Chicago, Ill.

Lindberg, Wm. A., engr. of circuit design and service investigation, Commonwealth Edison Co., Chicago, Ill.

Stock, Robert J., elec. engr., dept. of pub. utilities, Cincinnati, Ohio

## Applications for Election

Applications have been received by the secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the secretary before February 29, 1932.

## Order Form for Pamphlet Copies of A.I.E.E. Papers*

**Winter convention papers which are abstracted in this issue**

| Number | Author | Title |
|---|---|---|
| ☐ 32-29 | H. V. Putman | Surge-Proof Transformers |
| ☐ 32-47 | C. M. Hathaway and R. C. Buell | An Automatic Oscillograph |
| ☐ 32-48 | I. H. Summers | Vector Theory of Circuits Involving Synchronous Machines |
| ☐ 32-49 | K. K. Palueff and J. H. Hagenguth | Effect of Transient Voltages on Power Transformer Design—IV |
| ☐ 32-50 | A. L. Atherton | High Capacity Rectifier Efficiency Improved by Sectionalizing |
| ☐ 32-51 | E. W. Brown | Time and Its Measurement |
| ☐ 32-52 | A. L. Loomis and W. A. Marrison | Modern Developments in Precision Clocks |
| ☐ 32-53 | W. C. Hahn and C. F. Wagner | Standard Decrement Curves |
| ☐ 32M4 | C. F. Wagner and S. H. Wright | Calculation of Short Circuits on Power Systems |
| ☐ 32M5 | W. C. Hahn | Decrement Curves for Specific Systems |
| ☐ — | M. H. Woodward and A. F. Connery | Direct Printing Over Long Non-Loaded Submarine Telegraph Cables |

**Papers presented prior to September 1931 and upon which articles in this issue are based**

| Number | Author | Title |
|---|---|---|
| ☐ 31-92 | C. H. Sanderson and E. B. Ricketts | Automatic Combustion Control |
| ☐ 31-101 | D. D. Higgins and E. Wild | Reestablishing Excitation of a Loaded Alternator in Parallel with Others |
| ☐ 31-112 | H. W. Dodge and C. H. Willis | A Corona Tube Voltage Regulator |

*Members, Enrolled Students, and subscribers are entitled to one pamphlet copy of any paper in this list if requested within one year from above date. Thereafter a charge of 25 cents per copy will obtain.

*Address* **Order Department A.I.E.E.**

# Engineering Literature

## New Books

### In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during December are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

HANDBOOK OF INDUSTRIAL ELECTRICITY. By M. Kushlan. N. Y., McGraw-Hill Bk. Co., 1931. 535 p., 7x5 in., lea., $4.——A non-technical reference book for those engaged in electrical construction, maintenance, testing, inspection and contracting. It covers wiring for light, power, telephones, and signals in buildings of all kinds and for outdoor installations. Estimating is discussed.

LES MACHINES A COURANTS CONTINUS. By R. Langlois-Berthelot, with a preface by M. Paul Janet. Paris, Gauthier-Villars et Cie, 1931. 289 p., 10x7 in., paper, 75 Fr.——An elementary treatise on continuous-current machines discussing the principles, characteristics, and uses of dynamos and motors from a modern point of view, well fitted to prepare the reader for the study of a-c. machinery.

PERSONNEL MANAGEMENT. By W. D. Scott, R. C. Clothier and S. B. Mathewson. 2nd ed. N. Y., McGraw-Hill Bk. Co., 1931. 583 p., 9x6 in., cloth, $4.——A comprehensive outline of the principles of personnel management as they are understood and applied today, both to the management of individuals and of groups; summarizes experience of many employers; useful both as a text and for reference.

QUEST FOR POWER. By H. P. Vowles and M. W. Vowles. London, Chapman & Hall, Ltd., 1931. 354 p., 9x6 in., cloth, 15s.——The aim of the authors is to present a systematic, connected survey of modern progress in power engineering, displayed in proper perspective against a historical background and suitable for the general reader. This object has been accomplished with unusual success.

POLYPHASE INDUCTION MOTORS. By L. Lagron, trans. fm. French by R. C. Simpson and M. G. Say. London & Glasgow, Blackie & Son, Ltd., 1931. 218 p., 9x6 in., cloth, 15s.——The theory, design and use of the polyphase induction motor and its simpler variants are clearly and concisely described. The complete design of a 45-hp. low-voltage motor is worked out for both slip-ring and cage rotors. A chapter is devoted to testing, and another to power-factor correction and speed control.

YOUR HEALTH—AND YOUR EARNING POWER. N. Y., N.E.L.A., 1931. 181 p., 9x5 in., cloth, $0.65.——This book, prepared for distribution to employees of industrial concerns, is an instructive, non-technical handbook on the care of the body in health and disease. Diet, living habits, personal hygiene, disease prevention, first aid in illness, home nursing and first aid in accidents are discussed in simple, practical fashion.

ALTERNATING - CURRENT BRIDGE METHODS. By B. Hague. 2 ed., Lond. & N. Y., Isaac Pitman & Sons, 1931. 391 p., 9x6 in., cloth, $4.50.——Provides a fairly complete account of the theory and practical working of these methods, useful to post-graduate workers and those engaged in original research or accurate testing. Field is restricted to frequencies not exceeding those used in telephonic research. New edition, revised. Numerous references to original sources.

### ENGINEERING SOCIETIES LIBRARY

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

BALANCING OF MACHINERY. By C. N. Fletcher. Lond., Emmott & Co., 1931. 172 p., 9x6 in., cloth, 10s 6d.——Balancing of high-speed machinery is discussed from the point of view of the production engineer. The book summarizes the factors that affect balance, describes the better known apparatus for detecting unbalance, and the methods and calculations involved in correcting. Treatment is entirely practical.

COMMUNICATION. By D. O. Woodbury. N. Y., Dodd, Mead & Co., 1931. 280 p., 8x6 in., cloth, $2.50.——A popular account of the evolution of communication by telegraph, telephone, radio, and mail.

INCREDIBLE CARNEGIE, the Life of Andrew Carnegie (1835-1919). By J. K. Winkler. N. Y., Vanguard Press, 1931. 307 p., 9x6 in., cloth, $3.50.——Carnegie's spectacular rise from poverty to great wealth is told in interesting, journalistic fashion in this biography.

INDUSTRIAL HYGIENE for Engineers and Managers. By C. P. McCord, assisted by F. P. Allen. N. Y. & Lond., Harper & Brothers, 1931. 336 p., 10x6 in., cloth, $5.——A handbook on all phases of the preservation of life in industry, in which the latest methods of disease and accident prevention are discussed from the points of view of the physician and the executive.

INTERNATIONALER STROMAUSTAUSCH. By K. Dohrn. Munster i. Westf., Helios-Verlag, 1931. 69 p., 10x6 in., paper, 3.75 RM.——International electrical power networks being formed in Europe and America give rise to important economic and political questions, which are discussed in this pamphlet. The evolution and present condition of international interconnections in Switzerland, Austria, Scandinavia, Germany and Canada are discussed, and the policies adopted are studied.

RADIO TELEGRAPHY AND TELEPHONY. By R. L. Duncan and C. E. Drew. 2 ed. revised and enlarged, N. Y., J. Wiley & Sons; Lond., Chapman & Hall, Ltd. 1931, 1,046 p., 9x6 in., cloth, $7.50.——A comprehensive work, intended for use as a text-book by students and as a practical handbook by operators. The authors have aimed to cover the entire field, from the principles involved to the present complex application of them, in a simple, non-mathematical way.

WIRELESS. By L. B. Turner. Cambridge (England), University Press; New York, Macmillan Co. 1931, 528 p., 9x6 in., cloth, $8.50.——This book aims to present an account of radio theory and practise within the field of telegraphy and telephony which will be readable by a competent electrical engineer who has not studied high-frequency phenomena. The work will be useful to serious students who have passed the elementary stage.

# Selected Items From Current Literature

SELECTED references to current electrical engineering articles from Engineering Index Service's review of some 2,000 technical periodicals are given in the following columns. All articles indexed are on file in the Engineering Societies Library, New York, which will furnish photoprints of any article at a cost of 25 cents per page, or make translations of foreign articles at cost.

### AIRCRAFT

**Electric Equipment.** Applications of Electricity in Aircraft, H.A.Campbell. *Aviation Eng.*, v 5, Nov '31, p 13-17. Table gives maximum length to which circuits may be expected to be run; electrical calculations for twin-engined flying boat; wiring diagrams; generators and regulators; battery performance.

A Power Plant that Flies, R.E.Hudson. *Elec. Jl.*, 28, Nov '31, p 605-9. Electrical system designed to combine 100 per cent dependability with extraordinarily light weight.

### ARMATURES

Checking Winding Data with Slide Rule, W.O.Hurlbut. *Maintenance Eng.*, v 89, Oct '31, p 503-4. Outline of method of checking winding data with slide rule with special marks on upper stationary scale.

### BUSBARS

Generator Lead Tunnel Satisfies Many Demands. *Elec. World*, v 98, Nov 21, '31, p 906-7. At Ariel hydroelectric development of Inland Power and Light Co., 13,800-volt leads, which tie 56, 250-kva. generator directly to step-up transformers with only disconnecting switches circuit, are carried through concrete tunnel under transformer platform; layout is shown in some detail.

### CABLES

Use of Buried Cable for Underground Construction, W.R.Bullard. *Elec. World*, v 98, Dec 12, '31, p 1054-7. Suggests extension of use of buried cable to effect construction economies; operating advantages and disadvantages of buried cable.

**Operation.** Cable Operation—'30. *N.E.L.A.—Comm. Rept.* no. 161, Oct '31, 29 p. Rate of failures on high voltage underground systems continued in '30, downward trend in evidence since '26.

**Research.** Cable Research. *N.E.L.A.—Comm. Rept.* no. 160, Oct '31, 6 p. Research projects conducted under direction of cable research subcommittee since its organization, *i.e.*, effect of temperature on rate of deterioration of impregnated cable paper; study of ionization in paper-insulated high-voltage cables; influence of residual air and moisture in impregnated paper insulation. Bibliography.

**Testing.** Acceptance Inspection and Testing of Cable. *N.E.L.A.—Comm. Rept.* no. 162, Oct '31, 12 p. Marked discrepancy encountered at times between measured resistance of conductor and its area has been found to be entirely due to errors in one or more of various measurements. Bibliography.

### COMMUTATOR BRUSHES

Brush Efficiency, A.A.A.Rodriques. *Maintenance Eng.*, v 89, Oct '31, p 495. Practical discussion of proper methods of obtaining high brush efficiency through proper operation and maintenance.

### CONDUCTERS

**Installation.** Raceway Simplified Installation of Converter Leads, S.Watkins. *Elec. World*, v 98, Nov. '31, p 966. Economy in installing runs of heavy leads between supply transformers and two 300- and 500-kva. new rotary converters was solved in industrial plant.

### CONVERTERS

Revamping Old Converters Improves Operation, R. H. Newton. *Power*, v 74, Dec. 8, '31, p 831. Edison Elec. Illum. Co. of Boston revamping 5 of its 2,250-kw., 60-cycle booster converters: design and constructional features.

### CONVEYORS

On and Off Up and Down Automatically, R.G.Lockett. *Maintenance Eng.*, v 89, Oct '31, p 491-4. Design, construction and operating details of automatic vertical conveyor; electric control features.

**Electric Drive.** Individual Drives Operate Cotton Gin Economically, W.D.Sinclair. *Elec. World*, v 98, Nov 21, '31, p 908-9. Features of drives in 10-unit cotton gin; new gin will turn out cotton on shipping platform at figure of 13 kw-hr. per bale; typical installations; specifications of motor drives.

### ELECTRIC FURNACES

**Annealing.** Strip and Sheet Annealing in Electric Furnace with Atmosphere Control, W.S.Scott. *Iron Age*, v 128, Dec 3, '31, p 1422-5 & 32. Design and operation of furnaces for bright annealing developed by Westinghouse E. & M. Co.; savings between $1.50 and $3.50 a ton. (To be concluded.)

**Carburizing.** Electric Carburizing Saves Labor of Eighteen Men, E.F.Davis. *Elec. World*, v 98, Nov 7, '31, p 827-8. By substituting mechanical furnace where elements of time and temperature are under sensitive control and making such a furnace as automatic as practical, two men with two 90-kw. electric furnaces are producing equivalent output to 20 men by old box furnace practise.

**High Temperatures.** Methods of High Temperature Treatment, P.P.Cioffi. *Franklin Inst.—Jl.*, v 212, Nov '31, p 601-12. Direct heating of wire and tape specimens in gases; inductive heating of toroidal specimens; sketch illustrates glass furnace, steel furnace, and Gaede 4-stage mercury diffusion pump.

### ELECTRONS

Classical Electrodynamics and Conservation of Energy, W.F.G.Swann. *Franklin Inst.—Jl.*, v 212, Nov '31, p 563-76. Theoretical mathematical analysis.

### ENGINEERS

**Engineering.** Engineer's Growing Civic Responsibilities, F.L.Stuart. *A.S.C.E.—Trans.*, v 95, '31, p 1294-1302. Presidential address at annual convention at Tacoma, Wash., July 8, '31.

Engineers' Opportunities, F.L.Stuart. *Civil Eng. (N.Y.)*, v 1, Dec '31, p 1337-9. Present economic depression is result of insufficient production in years following war; longer working hours and increased output will constitute essential step in progress toward prosperity.

Future Will Demand More Economics in Engineering, W.S.Monroe. *Elec. World*, v 98, Nov 21, '31, p 904-6. From practical point of view, economics of engineering become largely matter of recognizing importance that fixed charges on investment bear to ultimate value of enterprise; also economics need more engineering; central-station industry has little idle capital in over-built plants; no fear of necessity for rapid write-off of modern stations.

New Competition and New Horizons in Engineering, F.H.McDonald. *Civil Eng. (N.Y.)*, v 1, Dec '31, p 1361-3. Undeveloped fields and modern demands of profession; recent changes in engineering and business which give new outlooks; social responsibility; problems of using goods.

**Earnings.** '30 Earnings of Mechanical Engineers—III. *Mech. Eng.*, v 53, Dec '31, p 876-82. Clippings from chart book of A.S.M.E. committee; earnings in principal industries; earnings and type of work.

**Employment.** Keeping Engineer Employed, H.M.Friend. *Power*, v 74, Dec 8, '31, p 835-6. What some large corporations are doing to maintain their engineering forces intact; wage cuts have been equitable.

**Liability.** Designer of Failed Coal Pocket Guilty of Manslaughter. *Eng. News-Rec.*, v 107, Dec 3, '31, p 899 & 902; editorial p 871. Collapse of New York coal pocket, which caused death of 3 men and injury of 11 others, resulted in conviction of designer by jury for second degree manslaughter.

### GALVANOMETERS

Portable String Galvanometer for Use at Moderate Frequencies, E.W.Marchant, J.K. Burkitt and A.H.Langley. *Sci. Instruments—Jl.*, v 8, July '31, p 209-14. Frequency of vibration of 150-200 per sec.; to secure critical damping, string is arranged in oil-filled case; to maintain proportionality between deflection and current, string is supported at ends by springs. (To be continued.)

### GENERATORS

Parallel Operation of A-C. Generators—II, E.H.Stivender. *Pwr. Plant Eng.*, v 35, Dec 1, '31, p 1147-8. Consideration of use of current-limiting reactors, as related to parallel operation.

### HEAT TREATMENT

Steel Strip and Sheet Annealing in Electric Furnace with Atmosphere Control. *N.E.L.A.—Comm. Rept.* no. 22, Nov '31, 13 p. Report supplements N.E.L.A. Publication No. 141.

### IRON AND STEEL PLANTS

**Electric Frequency.** Follansbee, W.Va. Plant of Follansbee Brothers Company Changes from 25 Cycles to 60 Cycles, J.S.Murray. *Iron & Steel Engr.*, v 8, Nov '31, p 453-66. Old and new plants analyzed; change-over discussed in detail; total demand averaged 3,800 kva.; plant was 100 per cent in operation at time of change.

**Electric Power.** Steel Mill Electrification Reduces Production Costs. *Elec. World*, v 98, Nov 14, '31, p 878-9. Lowered costs result from increased production, difference between purchased power and steam expenses, reduction of unit electricity rate due to increased utilization as result of electrification; Carpenter Steel Co., Reading, Pa.

### LIGHT AND LIGHTING

This Ultraviolet Situation, M.Luckiesh. *Elec. World*, v 98, Nov 7, '31, p 829-32. Curative values of less importance than preventive ones; summary of evidence argues for artificial sunlight; combination of health radiation and illumination advocated.

Size of Object, Visibility and Vision, C.E. Ferree and G.Rand. *Illum. Eng. Soc.—Trans.*, v 26, Oct '31, p 820-56. Effect of changes in size of object on speed of discrimination is studied for different intensities of illumination and different relations of object to background.

### AIRPORT

U.S. Aerodrome Lighting, K.W.Mackall. *Aircraft Eng.*, v 3, Nov '31, p 285-90. Characteristics of various types of lights in current use.

### INDUSTRIAL

Automatic Control of Industrial Lighting, E.H.Vedder and S.G.Hibben. *Mill and Factory Illust.* v 9, Oct '31, p 36-7. Survey of advantages of automatic control; circuit diagram of typical photo-cell automatic unit shows standard Mazda lamp used for pilot.

**Visual Efficiency.** Light and the Human Machine, M.Luckiesh. *Elec. World*, v 98, Dec 5, '31, p 1001-2. Eyes of subjects were tested at beginning and again at close of day's work; results compared and tabulated.

### LINES

**Losses.** Determining Tie Line Losses, H.Estrada and H.A.Dryar. *Elec. World*, v 98, Oct 24, '31, p 745-50. Tie line losses may have considerable effect on economical load allocation and decisions for interchange of energy; method of applying increment losses to these problems; other applications of increment loss are enumerated.

**Rural.** Characteristics of Rural Electric Lines, C.P.Wagner. *Agric. Eng.*, v 12, Nov '31, p 413-15. Presents detailed statistical analysis of territory under discussion.

### LOUD SPEAKERS

Use of Rochelle Salt Crystals for Electrical Reproducers and Microphones, C.B.Sawyer. *Inst. Radio Engrs.—Proc.*, v 19, Nov '31, p 2020-9. Methods developed permit cheap commercial production of Rochelle salt crystals; microphones, pick-ups, and especially speakers are described.

### MOTORS

**Protection.** Thermal Cutouts for Protecting A-C. Motors, H.D.Braley. *Power*, v 74, Nov 17, '31, p 703-5. Thermal cutouts for overload protection compared with protective devices that provide short-circuit protection; characteristics of devices for properly protecting motors against overloads, and types of thermal cutouts.

**Windings.** Winding Calculation Reduced to Single Slide-Rule Setting, W.O.Hurlbut. *Elec. West*, v 67, Nov 1, '31, p 228-9. Method of securing motor winding layout permits easy, rapid calculation of turn per phase and wire size for any given frame size.

### NETWORKS

**Design.** System Plan Alternatives Visualized for Executives, M.M.Samuels. *Elec. World*, v 98, Oct 31, '31, p 778-82. Expansion forecasting affected by current uncertainties; load prognostication on population basis safer than on customer total; significance of each plan can be condensed to tabular form for executive action; sample form used by author for analyzing plan.

**Fluctuation.** Starting Currents on Networks, L.O.Bell. *Elec. Jl.*, v 28, Nov '31, p 615-7. Duquesne Light Co. has tested low tension network to determine how much current can be drawn without causing noticeable flicker in lights.

**Losses.** System Losses—Their Analysis and Reduction, M.M.Koch. *Elec. World*, v 98, Nov 28, '31, p 948-51. Procedure to be followed in analyzing losses; methods of reducing them; samples of balance sheets and form used for detailed analysis of losses.

### OSCILLOGRAPHS

Cathode-Ray Oscillograph Timing Axis, F.T. Brewer. *Electronics*, v 3, Dec '31, p 222-3. Principles of performance of sweeping circuit; circuit diagrams and characteristics.

### PHOTOELECTRIC CELLS

A New Selenium Tube, G.F.Metcalf and A.J. King. *Electronics*, v 3, Dec '31, p 234-5. Characteristics of new FJ-31 cell manufactured by Gen. Elec. Co.; data on typical circuits. Bibliography.

**Applications.** Electronic Control of Machinery, R.F.Yates. *Iron Age*, v 128, Nov 19, '31, p 1299-1300 & 1349. Production gages, in which movement of anvils is amplified electrically by vacuum tube; grid-glow tube used in new stroboscope.

### PHOTOMETERS

Automatic Recording Photoelectric Cell Distribution Photometer, W.F.Little and H.J. Eckweiler. *Illum. Eng. Soc.—Trans.*, v 26, Oct '31, p 810-19. Efforts made to develop recording photometer which accurately integrates flicker from rotating luminaire and which completes, in time short enough to be practicable, continuous-curve record giving complete average candlepower data in surface of sphere.

## POLES, WOODEN

Making of Holding Tests of Guy Anchors. *Telephony*, v 101, Nov 21, '31, p 33-4. Method of making field tests of various types of anchors; photographs show set-up for experiments and also types of failure encountered.

## POTENTIOMETERS

Simple Method for Measurements of Residual Inductance on Potentiometers and Four-Terminal Resistance Coils, N.F.Astbury. *Sci. Instruments—Jl.*, v 8, July '31, p 221-3. Simple bridge method is described for measurement of inductances of potentiometers and four-terminal resistances.

## POWER PLANTS

**Diesel-Electric.** Diesel Stand-By Power in Hydro-Electric Plant, E.Swan. *Power*, v 74, Nov 17, '31, p 708-9. Design and operating characteristics of Central Power Company's Diesel Plant at Kearney, Nebraska; list of equipment.

**Hydroelectric.** Ice As Affecting Power Plants. *A.S.C.E.—Trans.*, v 95, '31, p 1134-5. Final report of committee of power division; surface formations; bottom formations. Bibliography.

Ice Prevention at Racks of Hydraulic Plants. *Pwr. Plant Eng.*, v 35, Nov 15, '31, p 1109-10. Description of two installations of electrically heated racks, also of open-channel and other mechanical methods.

Beauharnois Harnesses St. Lawrence for 2,000,000 Hp. *Elec. World*, v 98, Nov 14, '31, p 860-5. Provision also made for deep waterway; electrically driven machinery used for excavation; detailed illustration of operating gallery between wheel and generator levels.

Safe Harbor Development Adopts Kaplan Turbines. *Elec. World*, v 98, Dec 5, '31, p 992-6. Features of Holtwood plant of Pennsylvania Water & Power Co., and Conowingo plant of Susquehanna Power Co.

**Steam-Electric.** Operating Features of Station A, (San Francisco) C.E.Steinbeck. *Power*, v 74, Nov 17, '31, p 697-702. Summary providing background for detailed operating procedure; diagrams of piping.

## POWER SUPPLY

**Current Theft.** Current Theft and Its Prevention, S.A.Fletcher. *Elec. World*, v 98, Nov 21, '31, p 924-6. Notes on extent of practise; various methods of connecting meter boxes providing means of prevention.

**Rural.** Declares Rural Lines Cost Too Much, J.H.Matthews. *Elec. World*, v 98, Nov 28, '31, p 952-3. Author finds no reason for present farm line costs or quality; contends adequate low cost construction should be standardized.

## RADIO

**Amplifiers.** Audio-frequency compensation methods, J.G.Aceves. *Electronics*, v 3, Dec '31, p 224-5. Methods of compensation of losses in radio-frequency end of radio receivers in audio system; notes on reinforcement of high audio-frequencies and frequency band suppression; use of circuit as scratch filter for phonograph reproduction.

**Antennas.** Radiation Resistance of Complex Antennas, K.Tani. *Nat. Research Council Japan—Reports*, v 1, Aug '31, p 185-97. Theoretical mathematical analysis. (In English.)

**Detectors.** Grid Circuit Linear Detection, J.R.Nelson. *Radio Eng.*, v 11, Nov '31, p 32-4. If same results as are obtained with present detectors could be obtained by less radio-frequency voltage, cheaper radio-frequency amplifier could be used.

**Engineering.** Second Meeting of the International Technical Consulting Committee on Radio Communication, Copenhagen, '31. *Inst. Radio Engrs.—Proc.*, v 19, Dec '31, p 2219-49. 21 opinions which were unanimously approved at the '31 C.C.I.R. meeting are given together with 14 questions for consideration at third meeting to be held in Lisbon, Portugal; list of members of U.S. delegation.

**Frequency.** Notes on Generation of Absolute Frequencies, T.Kujirai and S.Fujitaka. *Nat. Research Council Japan—Reports*, v 1, Aug '31, p 199-201. Authors tried to eliminate intermediate standard tuning fork; generated required frequencies directly from oscillation of pendulum made of single steel rod, with period of about 1.093 sec., kept swinging with constant amplitude. (In English.)

**Interference.** Methods for Measuring Interfering Noises, L.Espenschied. *Inst. Radio Engrs.—Proc.*, v 19, Nov '31, p 1951-4. Various methods of measuring interference which have been found useful in Bell System.

**Measuring Instruments.** A direct Reading Modulation Meter, A.H.Cooper and G.P.Smith. *Wireless Engr. and Experimental Wireless*, v 8, Dec '31, p 647. Instrument does not require calibration from oscillograph or other apparatus; wiring diagram is given.

**Modulators.** Amplitude, Phase, and Frequency Modulation, H.Roder. *Inst. Radio Engrs.—Proc.*, v 19, Dec '31, p 2145-76. Comparative theoretical study of amplitude, phase, and frequency modulation. Bibliography.

**Oscillators.** Constant Frequency Oscillators, F.B.Llewellyn. *Inst. Radio Engrs.—Proc.*, v 19, Dec '31, p 2063-94. Manner in which frequency of vacuum tube oscillators depends upon operating voltages; theory of dependence derived; experimental data showing degree of frequency stability which may be expected as result of application of methods outlined in theory.

A New Treatment of Electron Tube Oscillators With Feed-Back Coupling, C.K.Jen. *Inst. Radio Engrs.—Proc.*, v 19, Dec '31, p 2109-44. Theoretical mathematical analysis.

A Recent Development in Vacuum Tube Oscillator Circuits, J.B.Dow. *Inst. Radio Engrs.—Proc.*, v 19, Dec '31, p 2095-2108. Constant frequency oscillator of two-anode type (UX-865) is described.

Adjustment of Multivibrator for Frequency Division, V.J.Andrew. *Inst. Radio Engrs.—Proc.*, v 19, Nov '31, p 1911-17. In multivibrator controlled by voltage of another frequency bearing harmonic relationship to multivibrator frequency, effect of varying control voltage is analyzed; method for determining best value of this voltage.

Neon Tube Audio-Frequency Oscillator, D. Pollack. *Radio Eng.*, v 11, Nov '31, p 24-5. Surface details and characteristics of oscillators which may be used in any position where sinusoidal waveform is not essential.

Vacuum Tubes as High-Frequency Oscillators, E.D.McArthur and E.E.Spitzer. *Inst. Radio Engrs.—Proc.*, v 19, Nov '31, p 1971-82. Problem of tubes for generating power at wavelengths below five meters is discussed; essential data are given for examples of each type of tube. Bibliography.

**Research.** Recording Characteristics of Radio Signals and Static, S.R.Winters. *Radio Engr.*, v 11, Nov '31, p 36-8. Three-in-one instrument, developed by radio laboratory of Bureau of Standards, measures strength of broadcasting stations, denotes fading of radio signals, and records static; 100-acre laboratory for radio transmission research is established near Fairfax, Va.; description of equipment and circuit diagrams.

**Telephone.** Radio Telephony by Ultra Short Waves, S.Uda. *Nat. Research Council Japan—Reports*, v 1, Aug '31, p 203-5. In previous experiments with decimeter waves, transmitter and receiver were different in construction, so that, for two-way communication, separate transmitter and receiver were needed; equipment much improved and single set now used both for transmitter and receiver.

**Transmission.** Some Observations of Behavior of Earth Currents and Their Correlation with Magnetic Disturbances and Radio Transmission, I.S.Bemis. *Inst. Radio Engrs.—Proc.*, v 19, Nov '31, p 1931-47. Radio transmission data collected on telephone circuits operating between New York and London and between New York and Buenos Aires; earth current data collected on two Bell System lines extending 100 mi. north and west from New York.

New Methods of Frequency Control Employing Long Lines, J.W.Conklin, J.L.Finch and C.W.Hansell. *Inst. Radio Engrs.—Proc.*, v 19, Nov '31, p 1918-30. Practical difficulties encountered in commercial operation of short-wave transmitters summarized; methods for meeting these objections through frequency control by long radio-frequency transmission lines.

**Transmitters.** Frequency Stabilization of Radio Transmitters, Y.Kusunose and S. Ishikawa. *Nat. Research Council Japan—Reports*, v 1, Aug '31, p 157-83. Experimental research with regard to frequency stabilization by means of constant-frequency oscillator; quartz-stabilized oscillator; mechanically-stabilized oscillator; valve-stabilized oscillator. (In English.)

**Waves.** Polarization of High-Frequency Waves and Their Direction Finding, S.Namba, E.Iso and S.Ueno. *Inst. Radio Engrs.—Proc.*, v 19, Nov '31, p 2000-19. Results of experiments which were conducted during past two years for purpose of studying high-frequency transmission phenomena, and some physical explanations deduced therefrom.

## RAILROADS

**A.E.R.A. Reports.** Electrical Section Reports. *A.R.E.A.—Bul.*, v 33, Aug '31, 84 p. Synopsis of reports of electrical section.

**Lackawanna Electrification.** A series of articles dealing with "major features," "new features," "power supply and distribution," "mercury arc rectifiers," "catenary system," "signals and interlocking system," "substations," "testing," etc., occupying practically the entire issue of the Gen. Elec. Rev., v 34, Nov '31, p 597 ff.

**Train Control.** Electronic Equipment in Train Control. *Electronics*, v 3, Dec '31, p 218-20. Reliability of vacuum tubes in industrial applications is shown by their practical use in railway signal control systems.

## RELAYS

**Photoelectric.** Light-Sensitive Relays Now on the Market. *Electronics*, v 3, Nov '31, p 194-5. Discussion covers Westinghouse, General Electric, Allen-Bradley, and Burgess equipment now available commercially.

**Protective.** Automatic Live Line Selection, C.W.Jones. *Elec. World*, v 98, Nov 14, '31, p 876. Scheme developed to select live line under conditions where substation is tapped off two transmission lines through motor-operated air-break switches; wiring diagram.

## SUBSTATIONS

Outdoor Substation Design. *N.E.L.A.—Comm. Rept.* no. 164, Nov '31, 43 p. Notes covering details of substation structures, materials, equipment, and protection.

## TELEPHONE

**Industry.** Present Day Economics of Telephony, R.A.Lumpkin. *Telephony*, v 101, Nov 28, '31, p 14-16. Effects of "depression proof" industry idea in public mind; possibilities and problems of future as shown by results of efforts in past year; newly understood policies outlined.

**Measurements.** Attenuation Measurements on Telephone and Telegraph Lines, J.W.Horton. *Radio Eng.*, v 11, Nov '31, p 25-6. Apparatus and connections for measuring line attenuation by modification of standard method.

**Relays.** Characteristics of Strowger Relays, K.W.Graybill. *Telephone Engr.*, v 35, Nov '31, p 30-1 & 49. Characteristics of various special types of relays; graphs showing details of their operation.

## TELEVISION

New Television System, R.W.Tanner. *Radio Eng.*, v 11, Nov '31, p 27-8. System described has possibilities in throwing received picture directly upon screen, without employing lens; new type of mercury arc tube is used for illumination.

## VACUUM TUBES

New Electron Tubes—Facts and Rumors. *Electronics*, v 3, Dec '31, p 216-7. Editorial announcing new short-wave tube for television, *i.e.*, Triple-Twin tube of Cable Laboratories, combining detector and power stage in same envelope; r.f. pentodes with preliminary rating and characteristics.

**Cathode Ray.** Improvements in Cathode-Ray Tube Design, V.K.Zworykin. *Electronics*, v 3, Nov '31, p 188-90. Tube developed is of hot-cathode, high-vacuum type; focusing done electrostatically; special features afford many new applications of oscillograph, including use as television receiver.

**Cold.** A "Cold" Filamentless Radio Tube, C.W.Hough. *Electronics*, v 3, Nov '41, p 182-3. Tube developed by A.Hund of Ampere, N.J., operates as amplifier, modulator, detector, oscillator; note on cold tube invented in Germany, by G.Seibt.

**Pentode.** Pentode Tubes Used as Triodes, J.R.Nelson. *Electronics*, v. 3, Dec '31, p 226-7 & 254. Curves show pentode characteristics of 247-type, output current and harmonic content of power pentode, effect of by-passing self-bias resistance of push-pull pentodes, and power output and distortion of pentodes in parallel; features of tube used as triode.

**Screen-Grid.** Choosing a Screen-Grid Tube, R.DeCola. *Radio Eng.*, v 11, Dec '31, p 15-16, & 32. Experimental inquiry with reference to characteristics of '235, '551 and '224-type radio tubes.

**Transmitting.** Design and Development of High-Power Oscillator or Amplifier Tube UV-862, R.W.Larsen. *Radio Eng.*, v 11, Dec '31, p 18-22 & 30. Technical account of development of UV-862 transmitter electron tube; table of characteristics and construction details of tube.

**Voltmeters.** Vacuum Tube Theory and Practice. *Telephone Engr.*, v 35, Nov '31, p 23-4 & 36. New type of instrument known as rectifier-type voltmeter; used to measure voltage of any frequency from one to 30,000 cycles with fair accuracy; theory and use of rectifier type voltmeter in telephone plant testing work.

## WELDING

Control of Spot and Flash Welds, G.A. Hughes. *Welding Engr.*, v 16, July '31, p 33-6. Summary of tests on resistance butt welded joints; Lehigh University welding symposiums; comparative Brinell and Rockwell hardness tests made on resistance welds in low carbon steel.

**Houses, Steel-Frame.** Residences of Welded Steel Construction. *Eng. News-Rec.*, v 107, Nov 26, '31, p 839-40. Symposium consisting of 2 papers; comparative cost estimate of steel and wood-frame construction.

**Coal Mines.** Electric Arc Welding in Mines, C.Lee. *Elec. World*, v 98, Nov 28, '31, p 953-4. Economy of welding in coal-mine practise with various types of equipment; curves showing cost of resistance welding *vs.* motor-generator set.

**X-Ray Analysis.** Guaranteed by X-Ray Inspection, W.H.Shipman. *Am. Mach.*, v 75, Nov 5, '31, p 708-9. X-ray inspecting and testing methods at Barberton plant of Babcock and Wilcox Co; cost of continuous use will not be more than $5 per hr. ordinarily.

# Industrial Notes

**Construction Volume in 1931.**—In reviewing construction activities in the final quarter of 1931, as well as in the year itself, the F. W. Dodge Corporation finds that the 1931 total for all types of construction in the thirty-seven states east of the Rockies amounted to $3,092,849,500 in actual contracts awarded in that area. The year's final quarter produced a contract total of $530,141,700 for all classes of construction in these thirty-seven states. Of this total for the last three months of the year, 34 per cent represents construction of public works and utilities, which amounted to $180,178,200. This compares with 32 per cent of the whole in the final quarter of 1930.

**New Southern Agent For Corning Glass.**—The Corning Glass Works, Corning, N. Y., has announced the appointment of the W. L. Rose Equipment Company, in St. Louis, Mo., as agents for the sale of PYREX power insulators in the southern part of Illinois and eastern part of Missouri, and Arkansas, and the western part of Tennessee.

**New Speed Recorder.**—An operation and speed recorder has been developed by the Amthor Testing Instrument Company, Inc., 309 Johnson Street, Brooklyn, N. Y., which automatically produces a detailed record of the speeds and operation of any rotating machine during the entire day. It shows all starting and stopping periods, the revolutions per minute, fluctuations, etc., recorded directly from the action of the machine itself. A few of the more common applications are on turbines for recording operating speeds and the correctness of the over-speed or safety trip, and on engines and motors.

**New Pole-Top Switches.**—The Delta-Star Electric Company, Chicago, announces a new line of two and three-pole, gang operated pole-top switches for distribution line voltages up to 34.5 kv. The tilting insulator carries a hinged loop and as the switch opens this loop travels along, keeping the stranded conductor from dropping down, eliminating the usual hinged links. The insulator pins, levers and fittings are of malleable iron, the channel base of steel. All parts, bolts and nuts at line potential are of non-ferrous metal. Solderless clamp connector terminals are provided for connection to the line conductors.

**New Contact Alloys.**—Pitting of electrical contacts is said to be practically eliminated with the new contact alloys developed by P. R. Mallory & Company, Indianapolis, Indiana. These alloys possess marked advantages over ordinary contact materials. The specific applications are as follows: Alloy known as 3W3 is recommended for oil circuit breakers as well as interrupter contacts for resistance seam welders operating in air. Another, known as 20S, is suitable for arcing tips of very high current density. Still another, G11, is used for arcing tips of low current density and also for make and break contacts where current density is high and non-welding necessary. G13 is used for make and break contacts where current density is high and welding of contacts is not encountered.

**Allen-Bradley Exhibition of Motor Control.**—The most extensive exhibit of motor control equipment ever brought together in Chicago by a single manufacturer will take place during the four weeks beginning February 1st, when the Allen-Bradley Company, of Milwaukee, will display units representing their entire line of motor controllers and accessories. The fifth floor of the Engineering Building, at 205 West Wacker Drive, has been reserved for this display, which will consist of several hundred pieces of Allen-Bradley control equipment, ranging from their smallest photoelectric relay and push-button stations to their largest high-tension automatic starters. The complete line covers controllers for practically all industries and includes standard duty, water-tight, dust-tight, and explosion-proof equipment. The control circuits of the control devices on display will be connected to power feeders so the visitor can observe the operation of the equipment. The exhibit will be in charge of Eugene F. LeNoir, assisted by several members of the Allen-Bradley engineering staff, who, during the four weeks of the exhibit, will give frequent talks before groups of engineers and students.

# Trade Literature

**Transformers.**—Bulletin 148, 24 pp. Describes transformers for instrument and metering service. Allis-Chalmers Manufacturing Co., Milwaukee, Wis.

**Splice Boxes.**—Bulletin, 8 pp. Describes a new and comprehensive line of splice boxes which have been developed because of the increased popularity and possibilities of this type of cable joint. G & W Electric Specialty Company, 7780 Dante Avenue, Chicago, Ill.

**Gearmotors.**—Bulletin 20536, 4 pp. Describes Westinghouse "gearmotors," consisting of speed reducers combined with induction motors into single, self-contained units. Twenty reduction ratios of 1.12:1 to 10:1 are available for each motor speed and horsepower. Westinghouse Electric & Mfg. Co., East Pittsburgh, Penna.

**Motors.**—Bulletin H-1, 14 pp. Describes Star ball-bearing motors designed specifically for hoist duty, with and without built-in brakes. Star Electric Motor Company, Newark, N. J.

**Illumination.**—Bulletin 375-J, 52 pp. Comprises the Holophane "Datalog." This issue contains new developments on lighting equipment for 1932 and includes an engineering section and recommended standards of foot-candles illumination. Holophane Company, Inc., 342 Madison Avenue, New York.

**Ground Tester.**—Bulletin 1300, describes a new small, light weight, direct-reading instrument for measuring ground resistance. This instrument is mounted in a cast aluminum case and weighs 7½ pounds. James G. Biddle Company, 1211 Arch Street, Philadelphia, Penna.

**Floodlighting.**—Bulletin GEA-1505, 4 pp., Floodlighting for outdoor construction; Bulletin GEA-1506, 4 pp., Floodlighting monuments and memorials; Bulletin GEA-1507, 4 pp., Floodlighting for homes and estates; Bulletin GEA-1509, 4 pp., Illumination of parks. General Electric Company, Schenectady, N. Y.

**Mechanical Stokers.**—Catalog, 40 pp. A condensed catalog of mechanical stokers manufactured by fourteen different producers of such equipment. Included are brief but complete descriptions of the most prominent types of stokers. The descriptive matter is confined strictly to engineering data, permitting ready comparison of the various types. Stoker Manufacturers Association, Foot of Walker Street, Detroit, Mich.

**Transformers.**—Bulletin 3110. Describes a new constant current street lighting transformer. This transformer has a unique arrangement whereby both primary and secondary coils move through a small angle thus giving better regulation and a higher power factor. The new unit is represented as having many superior operating characteristics; quiet in operation, low in maintenance cost and has higher operating efficiencies. It is manufactured in all standard sizes from 3 to 30 kva. for both pole and subway use. Moloney Electric Company, 5390 Kingshighway-Bircher St., St. Louis, Mo.

**F.** L. HUTCHINSON, for the past twenty years national secretary and executive manager of the A.I.E.E., died suddenly, February 26. This sad event occurred during the closing of forms for this issue of Electrical Engineering, but we believe that the readers will pardon the resulting delay. *p. 202-203*

**W**OUND-ROTOR induction machines may be given special characteristics by connecting their rotors and stators in parallel. *p. 171-173*

**W**IDE flexibility in distance measuring characteristics is claimed for a new high speed relay developed especially for short power lines. *p. 157-160*

**G**ENERATOR overvoltage may increase rapidly following sudden loss of load, especially in hydro units; a method for calculating this rise, with a typical example, is given in this issue (*p. 163-167*). Tests show that such overvoltages can be limited to safe values by the use of suitable equipment. *p. 160-163*

**M**ANY A.I.E.E. leaders have received recent recognition in the form of promotions and special awards. *p. 209-214*

**H**AS modern civilization lived up to its lofty mission? Dr. M. I. Pupin, 1932 John Fritz Medalist, raises this question and gives his answer to it. *p. 156-157*

**T**APE armored telephone toll cable buried directly in the ground possesses several advantages over other types of line; special equipment has been developed for laying this cable. *p. 168-171*

**E**NGINEERS through local relief committees, have taken special measures to combat unemployment. Reports of surveys conducted by local A.I.E.E. sections indicate that conditions vary widely. *p. 205-207*

**P**OPULATION forecasts when carefully and intelligently made fill a real need in the planning of engineering projects. Such forecasts are especially valuable to the telephone industry in planning future plant expansion. *p. 185-188*

**L**AST CALL for the A.I.E.E. Great Lakes District meeting to be held March 14-16 at Milwaukee; a few minor changes have been made in the program (*p. 202*). All of the technical papers to be presented are abstracted in this issue. *p. 188-192*

**I**NTERCONNECTION of power systems, to be most advantageous, should be carried out only after a most careful study of the problems of each of the systems involved. Interconnection services are classified and evaluated, and the development and operation of interconnected systems discussed from various angles, in a group of four articles. *p. 174-185*

**A**.I.E.E. winter convention attracted 1,429 registrants, but this was only one of the many factors attesting its success. A report covering the many features of the convention including President Skinner's opening address, two medal presentations, fourteen committee meetings, and the board of directors meeting, may be found in this month's news section. Discussion at technical sessions will be treated in a later issue. *p. 193-202*

# The Engineer and His Responsibilities as a Citizen

**In his opening speech before the Institute at its 1932 winter convention in New York, N. Y., President Skinner stressed the contributions of the engineer to the material development of the country and toward maintaining a high standard of living. Because of his ability to judge the value of so many forms of national activity, the engineer's greater participation as a citizen was urged. Excerpts from Doctor Skinner's speech follow.**

DURING the last year or two we have heard much in regard to the part our so-called machine age has played in bringing about this period of depression and unemployment. We hear talk of over-production, of under-consumption, of difficulties in distribution, of necessity for shorter working hours, and many other similar questions. Without attempting in any way to discuss or pass on these questions it does seem desirable to point out that these changes, bringing about mass production through standardization and the application of the power driven machine, are inevitable and must and will continue.

These things have been going on ever since the first application of power to displace handicraft at almost the beginning of the last century. We might speak of this as the inevitableness of change, and change will continue so long as more effective methods and machinery are developed. Development cannot be stopped by declaring a holiday on research and invention. . . .

At this point it should be remarked that equalization of rates, equal control of operation, and taxation so adjusted that the old service does not help to support the new to its hurt, will, of course, in the end be beneficial to all concerned. When broadly interconnected power systems, with their highly efficient generating stations, either steam or water, can furnish dependable electric power at a cost much below that of the small isolated plant, the small plant must be abandoned. When there is devised, as has already been done, a continuous rolling mill which receives an ingot at one end and without pause keeps this metal moving until it is rolled up as a continuous sheet at the other end, the older type of sheet mill requiring its intense human labor must give way to the new order. These and a multitude of other changes have been and are under way. What is necessary above everything else in connection with such changes is that we adjust ourselves to these changes, and that there be as little disturbance as possible to those elements which are of necessity affected or displaced. This first of all applies to the human element involved in each case. Our relatively high living standard should not only be maintained but increased and extended to all who do their part in production and distribution.

We should endeavor so to adjust our laws and regulations that new and competitive devices of merit are on an equitable basis with those which have preceded them. This adjustment in many cases may well take the form of easement of the burdens of the older facilities as well as such equitable control of the newer that each may find its proper sphere of usefulness without detriment to the other. Perhaps the outstanding example of the need of such equitable arrangement is found in our transportation systems today. The engineer above all others should stand for fair dealing based on deductions brought about through unquestioned fact finding, and it is the engineer above all others who by training and experience is in the best position to arrive at correct conclusions in connection with many of the problems with which we are faced.

We hear much at the present time of the necessity for increased taxation. We hear comparatively little of reduction in expenses, which could be brought about by more orderly conduct of our affairs. For many years engineers have advocated more effective coordination and correlation of the public works functions of the Government. The President, in his recent message to Congress, has advocated legislation to bring this about, and . . . it is hoped that a bill for this purpose now pending before Congress will be passed, if for no other reason than to accelerate public construction in periods such as those which we have been experiencing during the last two years.

In what has been said, I have hinted at some of the problems before us as engineers, and I wish particularly to emphasize our responsibilities as citizens as well as engineers, urging participation in those larger affairs which affect not only engineers but all citizens of our country and in which the engineer is in a peculiar position to guide and to lead.

C E Skinner

# The Power Age and Modern Civilization

**Although the moving powers of heat and electricity have raised man's physical existence to Olympian heights, they have not worked similar miracles in his spiritual life. Engineers and scientists are called upon to banish fear and hatred from the human heart by application of that greatest power of all —the power of love.**

By
M. I. PUPIN
Honorary Member A.I.E.E.

Columbia University
New York, N. Y.

FARADAY'S DISCOVERY of electromagnetic induction, a hundred years ago, is the closing event of a great epoch in the history of physical science and engineering. It is the epoch in which the power age was born.

Watt's invention of the steam engine marks the beginning of this epoch. It suggested to the genius of Carnot the immortal idea embodied in his well known law. This law defines what Carnot called the moving power of fire, that is of heat, a name which today is one of the greatest names in physical science.

Carnot's interpretation of the moving power of heat completed in 1824 the first great step in the evolution of the power age. The second great step was made when in 1820 Oersted discovered the magnetic force of moving electricity and a few years later Faraday discovered the electric force generated by moving magnetism. The law of action of these forces defined the moving power of electricity just as Carnot's law defined the moving power of heat. We know today that these two moving powers are the fundamental physical powers in the universe, and that their revelation was the greatest achievement ever recorded in the history of engineering sciences. It inaugurated, a hundred years ago, the power age. This age is the parent of our present civilization and the moving powers of heat and of electricity are the propelling powers in the physical evolution of this civilization.

Our civilization very often is called the machine civilization and what I call the power age often is called the age of machines. I don't like these names for the simple reason that machines are the creation of the hands of mortal man. They are transient, but the moving power of heat and the moving power of electricity are eternal; these powers are the immortal elements in the physical structure of our civilization.

Advancement of science during the power age, that is during the last hundred years, revealed that the same fundamental powers which are at work in the evolution of our civilization were also at work in the evolution of organic life ever since life appeared on this terrestrial globe and that they are also the only propelling powers in the evolution of the luminous stars. Radiations from these stars tell us that the moving powers of heat and of electricity are of celestial origin; they were brought to earth on the wings of solar radiation and remained dormant until the genius of Watt, Carnot, Oersted, Faraday, and Henry called them to the service of man. This service is the service of our central star to this tiny terrestrial globe; its mission on this earth recalls the mission of the celestial flame which, according to an ancient legend, the Titan Prometheus snatched from the radiant chariot of the sun god Helios and brought down to earth. The ancients believed that the mission of that celestial flame was to make the life of man similar to the life of the Olympian gods.

We believe that the mission of the moving powers of heat and of electricity, our most precious gifts from our central star, is to raise the life of man to Olympian heights. But has our civilization, the offspring of the power age, lived up to the lofty aim of this mission?

Two pictures occur to me when I attempt to answer that question—two entirely different pictures. In one of the pictures I see the triumphant conquest of space by the automobile and the aeronautical art. I see the wonders of power distribution increasing a hundredfold the comforts and the creative power of man, and I am thrilled by the electric waves which gliding over wires or wandering through space convey on their wings speech and melody over continents and oceans to every nook and corner of this terrestrial globe. These are a few of the miracles of our power age by which the moving powers of heat and of electricity have displayed the magic of their celestial origin; they certainly have made the physical side of human life even more glorious than the life of the Olympian gods. This achievement of the power age is its greatest glory.

But the spiritual side of human life, exhibited by another picture, is far from edifying. In this second picture we see desolation on every side in the wake of the most deadly war which the world has ever seen. The world appears here standing on the verge of economic collapse, and yet vast armies and navies are devouring the meager remnants of the wealth of nations while millions of idle workers are starving. The most repulsive figures in this horrible picture are fear and hatred, which, like two ugly demons, are hovering on each side of the boundary lines between neighboring nations.

Banish these demons from the human heart and there will be no need of vast armies and navies to guard our security against hostile neighbors; there will be no hostile neighbors, and wars will become a dying memory only of former barbarous ages. But the celestial ser-

---

An address delivered by Doctor Pupin when the John Fritz Medal was presented to him at a special session of the A.I.E.E. winter convention on the evening of Jan. 27, 1932.

vants of our civilization, the moving powers of heat and of electricity, have not banished them.

Science admits that the magic of these two primordial powers cannot unaided purge the soul of man and eliminate the poisons which corrupt its spiritual life. Another moving power is sorely needed which can penetrate more deeply than the moving power of even the infinitely minute electrons into the depths of the human heart. This need was recognized nearly 2,000 years ago when our Saviour revealed the moving power in the spiritual world and commanded us to love the Lord our God, and to love our neighbors as ourselves.

This was a message of the approaching power age in the spiritual world. But this age has not yet arrived; mankind has not yet yielded to the greatest moving power in the spiritual world, and without its aid the moving powers of heat and of electricity cannot contribute their full share to the evolution of the spiritual life of man.

Love of the eternal truth and of their work to reveal this truth for the good of mankind has guided the scientists and engineers to the great triumphs of science. These triumphs of love will persuade the reluctant world that the victorious triumph of the moving power of love which Christ discovered will be the greatest triumph of the power age.

# A High Speed Relay for Short Lines

**A new high speed distance relay with composite impedance-reactance characteristic has been developed. This modification combines the mechanical simplicity of the impedance type relay having inherent possibilities for high speed of operation so desirable where stability is a factor, with, on the shorter lines, the greater independence of the reactance type relay from the effects of fault-resistance.**

By

S. L. GOLDSBOROUGH Westinghouse Elec. & Mfg. Co., Newark, N. J.
Associate A.I.E.E.

W. A. LEWIS Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Associate A.I.E.E.

TRANSMISSION of power over longer distances and the concentration of greater amounts of power over a single circuit have rendered the presence of a short circuit on the system a more serious matter, and a considerable effort therefore has been made to reduce the duration of the short circuits. The result has been the development of circuit breakers and relays operating to clear the disturbance in a very short time. The conventional type of induction overcurrent relaying, depending upon successively increasing time intervals to obtain proper selectivity between circuit breakers, is no longer suitable where the maximum speed is desired; and so a new form of relaying, known as distance relaying, has been developed for the general protection of transmission and distribution lines. Relays operating on the distance principle make use of the characteristic impedance or reactance of the circuit, as determined by comparing the voltage and current at the relaying point, to determine the distance from the relay to the fault. Hence, selectivity between circuit breakers can be obtained without the use of increasing time intervals in the time settings of relays as the generating station is approached.

The tripping-time characteristic employed with the new types of distance relays is shown in Fig. 1. When a fault occurs between station *A* and the point *m* the relay trips instantaneously. When a fault occurs between the point *m* and the point *n*, a time delay $t_1$ purposely is introduced in the relay at *A*. If the fault is between station *B* and the point *n*, the time delay introduced in the relay at *A* will allow the relays at *B* to trip the circuit breaker at *B* first, so the relay at *A* resets and does not trip its breaker. If, on the other hand, the fault is between *m* and *B* the breaker at *A* will be tripped after a time delay $t_1$. It is customary also to provide a third range of protection which will trip the circuit breaker at *A* after a time interval $t_2$, for a fault at any location between station *A* and the point *p*, if it is not cleared earlier by the action of other relay elements.

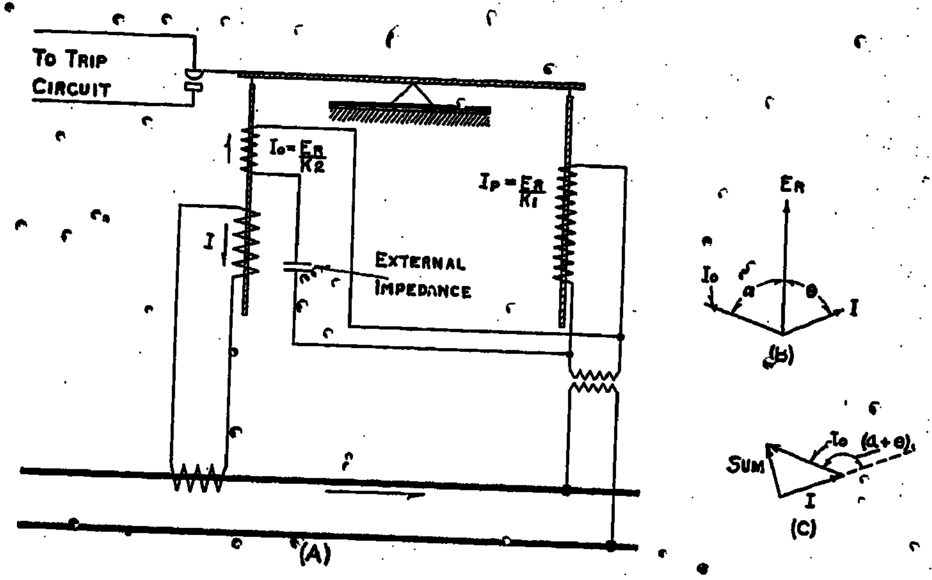

Fig. 2. Schematic diagram of new modified relay

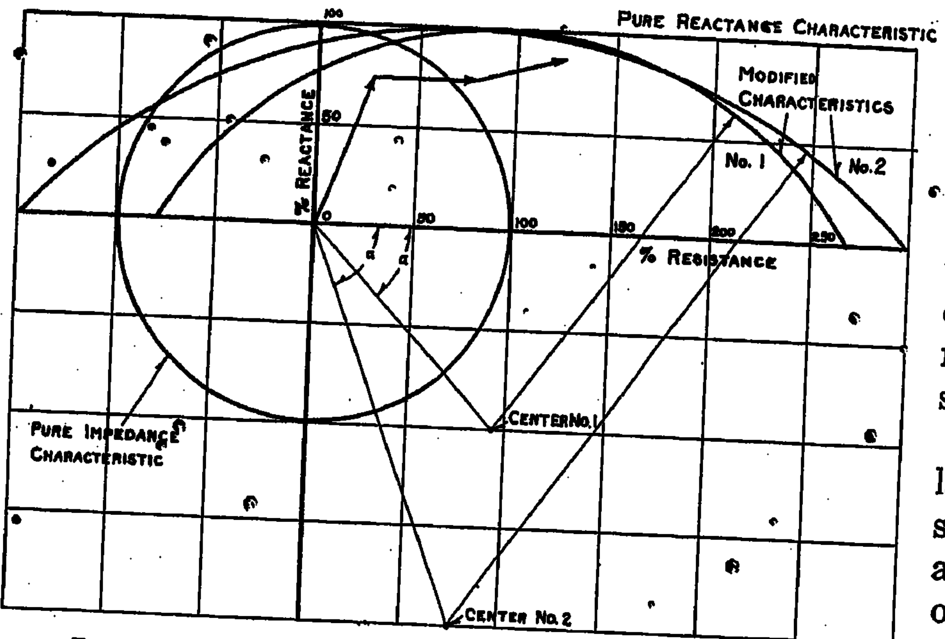

Fig. 3. Tripping characteristic of modified relay

Two general types of relays having the same time characteristics have been developed. These two types are impedance relays and reactance relays, the first of these operating on the impedance of the line between the relay and the fault, and the second on the reactance alone. Each of these types has advantages, but is subject also to certain disadvantages. The new relay described here combines the principal advantages of both of these types.

The new relay is essentially a modification of the simple balanced-beam impedance relay, as may be seen from Fig. 2. The impedance relay consists essentially of the balanced beam supporting two plungers. On one side of the relay a current coil acts to close the relay contacts and on the other side a potential coil acts to hold the contacts open. The modification, which gives the new relay its desirable characteristics, consists in the addition of a second voltage coil to the current side of the relay.

The simple impedance relay with one voltage coil and one current coil will balance when the pull of the current coil just balances the pull of the voltage coil. If the current pull increases the relay will operate to close the contacts to the trip circuit. The pull will just balance when the ratio of voltage to current is a definite constant, depending upon the design and adjustment of the relay. This constant ratio will be equal to an impedance, since impedance equals voltage divided by current. For all smaller values of impedance, the current pull will exceed the voltage pull and the relay will operate, whereas for all larger values of impedance the relay will not operate. This characteristic is shown graphically in Fig. 3 by the circle marked "pure impedance characteristic." In this figure per cent resistance is plotted along one axis and per cent reactance along the other. When the impedance is 100 per cent, the values of resistance and reactance plotted in this diagram will give a circle about the origin with 100 per cent impedance as a radius. Thus the relay trips for points lying within the circle, and does not trip for points lying outside of the circle.

The addition of the second potential coil on the current side of the relay does not change the fundamental circular characteristic of the relay, but, when plotted in the same form, has the effect of shifting the center of the circle and changing its radius. The new location of the center and the new value of the radius will depend upon the effectiveness of the second potential coil as well as on the phase angle of the current through this coil with respect to the current in the main current coil. Two such modified characteristics are shown in Fig. 3.

With the simple impedance relay, the presence of a large amount of accidental fault resistance, as may sometimes occur on relatively short lines, may cause the apparent impedance as measured by the relay to fall outside of the characteristic circle, when the impedance of the line alone, between the relay and the point of fault, would fall within the characteristic circle. For such cases the proper element of the relay would be prevented from tripping. The modified characteristics as shown in the figure greatly increase the area within which the relay will trip and thus overcome this difficulty.

A relay operating on a pure reactance characteristic, that is, one designed to trip for all values of reactance up to a given value, regardless of the fault resistance, would also largely overcome this difficulty. However, the apparent reactance of high power factor loads existing before the short circuit would be very low, so that such a relay would trip under load conditions unless prevented from doing so by auxiliary devices. It is difficult to give the auxiliary devices the exact characteristics needed, and in addition some time delay is introduced by their operation, which is undesirable where high speed of fault clearing is an important factor. The modified-characteristic relay overcomes this disadvantage also because the circular characteristics intersect the resistance axis at values of resistance which will prevent operation of the relay under the heaviest loads.

The manner in which this characteristic is used to obtain the desired tripping-time characteristic illustrated in Fig. 1 is shown in Fig. 4. Three distance measuring elements are used in the complete relay, the first tripping the circuit breaker instantaneously, the second and third elements operating through an adjust-

able timer to interpose the necessary adjustable time delays $t_1$ and $t_2$. Tests have shown that arc resistance is generally quite small at the inception of the fault, but that it may increase to rather large values if the arc is allowed to persist. This indicates that in the first zone in which the relay is designed to trip instantaneously the error in distance measurement due to the effect of arc resistance will not seriously affect the operation of the relay, so that the simple impedance element may be used. However, in the second zone of the relay, such as between $m$ and $n$ in Fig. 1, where a definite time purposely is introduced into the operation of the relay, the arc resistance may increase to important values. Hence, on the shorter lines, the arc resistance may become large enough in comparison with the impedance of the line section to affect the operation of the relay, and the use of the modified characteristic as shown in Fig. 4 is indicated for the second distance element of the relay. The third distance element is provided for back-up protection only, and may be set to balance for faults so remote that the arc resistance will not affect its operation. Hence, a pure impedance element may likewise be used for the third element. Thus, referring to Fig. 4, for a fault between $m$ and station $B$, where a time delay $t_1$ is required, values of fault resistance considerably in excess of the impedance of the section may be permitted without affecting the performance of the relay in any way.

The complete relay is shown in Fig. 5. In addition to the three distance elements and the timer already mentioned, there is included a sensitive directional element to insure that the relay will trip only when the fault is in the proper direction from the relay.

Mechanically the three distance measuring elements are duplicates. However, on the second element the voltage coil on the current side is provided in order to obtain the desired modified characteristic. The voltage side of each element is provided with two voltage coils, instead of the single coil indicated in Fig. 2, in order to prevent chattering and the tripping of the beam during the period when the voltage is going through zero. These two coils have separate cores but are so arranged that the beam completes the magnetic circuit in each case, and the fluxes in the two cores are shifted in phase from each other so that a practically constant voltage restraint is produced.

The timing element consists of a small floating-armature synchronous motor driven from a small saturating current transformer. The motor drives a bridging contact through suitable reduction gears so as momentarily to bridge two sets of stationary contacts which can be shifted independently on a scale in order to vary the timing. The motor normally is prevented from operating by a normally closed contact on the third or back-up distance element of the relay, which of course operates for all faults within the range of the relay. The maximum time is adjustable up to approximately 3 sec.

The directional element is of the pure wattmeter type and consists of a rectangular aluminum loop which acts as the short-circuited secondary of a small potential transformer and rides in a magnetic field produced by two current coils. Motion about the pivoted axis of the loop thus is produced and the direction of the motion is dependent upon the relative polarity of the current and voltage.

The new relay is intended for application to the shorter line sections, where the arc resistance may reach comparatively large values, for protection against line-to-line, double line-to-ground and three-phase faults. To prevent differences in the distance measurement depending upon the type of fault, the current windings of the relay should be connected to utilize the difference between the currents flowing in the two line conductors to which the relay is assigned, and not the current in a single line, since the latter would produce errors amounting to 15 per cent or perhaps even more depending upon which of the types of fault occurred.

The factor which limits the length of line to which the relay can be applied is the requirement that the element with the composite characteristic must not operate on load currents. The longer the line the greater is the possibility of this occurring, and for the particular characteristic discussed, the limit is approximately 2 ohms, measured in terms of the secondary voltages and currents applied to the relay.

The principle employed in the new relay is particularly valuable in that it imparts a wide flexibility to the distance measuring characteristics. Where necessary, it can be applied to any one or all of the three elements and practically any sort of characteristic which experience may indicate to be desirable can be obtained by proper choice of characteristics for the auxiliary coil.

# Generator Overvoltage when Dropping Load

Sudden dropping of load tends to result in overvoltage of generators. Tests show definitely that such overvoltage can be prevented by the use of high speed regulators and bridge type field rheostats, or by inserting resistance automatically in the generator field circuit.

By

TOTAL or partial loss of load on waterwheel-driven generators or hydroelectric stations frequently results in undesirable voltage rise, and in such cases it is desirable to limit this voltage rise in order to avoid overstressing the insulation of generators and connected apparatus.

In the past this sometimes has been accomplished by use of overvoltage, overspeed, or overfrequency relays which automatically open the field circuit and trip the generator from the line or bus when the voltage or speed reaches a predetermined value. This is a very effective way of limiting the overvoltage, but it has the disadvantage of making necessary the resynchronization of the different machines in a station, to get them back into service.

In an earlier article ("Over-Voltage on Transmission Systems Due to Dropping of Load," A.I.E.E. TRANS., 1925, V. 44, p. 872-80) was shown the manner in which under various conditions transmission line voltage will rise as a result of load dropping. The purpose of this paper is to show how the voltage on a waterwheel generator or hydroelectric station may be held within reasonable limits at a time when full load is suddenly lost, without opening the field circuits of the machines or tripping them from the line or bus.

Information given is based upon the results of tests made on a 47,000-kva. generator at the Spier Falls plant of the New York Power and Light Corporation. In these tests use was made of a newly developed high speed generator voltage regulator and a wheatstone bridge type of main exciter field rheostat which made possible the quick reduction of generator field current thereby limiting the generator voltage. Tests were made also upon the same generator to show the possibilities of limiting generator voltage by automatically inserting resistance in the alternator field.

In Fig. 1 is given a simplified diagram of the test connections used including a six-element oscillograph. The main exciter is compound wound, but as tests were desired for a shunt wound exciter, a switch was arranged to insert an 0.08-ohm resistor in the alternator field circuit to change the time constant of the circuit to a value simulating that of a shunt wound main exciter. There being no low voltage bus or circuit breaker, load always was dropped in the tests by tripping the transformer high voltage circuit breaker.

## REGULATOR EQUIPMENT

The wheatstone bridge rheostat shown in Fig. 1 is suitable where it is desirable to reduce the main exciter voltage to a very low value or reverse it, or when the very quick reduction of exciter voltage is desirable, as in the case under consideration.

Arms marked *A* are operated simultaneously by motor *M*. Arms marked *B* are operated simultaneously by a handwheel to give the desired voltage reduction when the high speed relays *X* open. In the case under consideration a setting was made such that when relays *X* opened, the main exciter armature voltage was reduced to a negative value of approximately 10 volts.

The primary control element, Fig. 2, of the high speed regulator used consists of a three-phase torque motor, to the rotor of which are attached two pairs of contacts. Of these, both front and rear make contact with disks connected to a shaft driven at constant speed by a

---

small a-c. motor. The front disk has cam shaped teeth while the rear disk is smooth.

This regulator remains inoperative with both pairs of contacts out of engagement as long as no change in excitation is required. For slight changes in voltage only the front contacts $L_1$ and $R_2$ and the motor operated field rheostat are affected, a "notching" action resulting varying from a single brief impulse to practically continuous operation of the motor depending upon the correction required. Only for greater changes in voltage do the back contacts $L_2$ and $R_2$ and the high speed relays $X$ and $Y$ come into action to maintain the voltage until the motor operated rheostat has moved to a position corresponding to the required excitation.

The notching action of the front contacts in conjunction with the intermittent operation of the rheostat prevents overtravel of the latter with consequent hunting. The back contacts go into operation when the a-c. voltage has changed from 3 to 15 per cent, according to the adjustment made. The regulator will hold constant voltage for all frequencies between 25 and 85 cycles.

## RESISTANCE IN FIELD CIRCUIT

In Fig. 3 are indicated the connections and devices used to insert resistance automatically in the alternator field circuit upon the occurrence of overvoltage. The contact making voltmeter type of overvoltage relay endeavors to hold a-c. voltage in accordance with its setting by repeatedly opening and closing a contactor connected across a resistor in the alternator field circuit. As soon as the contactor opens, the setting of the overvoltage relay may be changed if desired to hold normal voltage or a voltage of some predetermined value. This change in the setting of overvoltage relay is accomplished by the use of a hand reset relay which, upon closing its contacts, changes the value of resistance in the coil circuit of the overvoltage relay. In the case under consideration the overvoltage relay was set to operate at approximately 16.8 kv. or 22 per cent above normal voltage.

## TEST RESULTS

Results of dropping load on the 47,000 kva. generator under the conditions mentioned are shown in Figs. 4, 5, and 6. When load was dropped, there were two or three cycles of single-phase operation caused by the three poles of the 110-kv. circuit breaker not opening at exactly the same moment. Because of this it may be noticed that the alternator field current did not decrease instantaneously at zero time, but dropped to its new value in about three cycles, which is reasonable when it is considered that it took that time to drop the load completely. In all cases where a 40,000-kw. load was dropped, a maximum of 138 per cent of normal speed was reached in approximately 3.5 sec.

Referring to Figs. 4 and 5, approximately 4 per cent higher alternator voltage was obtained with the compound than with the shunt connected main exciter when a 40,000-kw. load was tripped, using the wheatstone bridge arrangement. Also, with the shunt exciter the overvoltage was reduced more quickly than with the compound exciter. When using the shunt exciter the maximum voltage was 16.5 kv. or approximately 20 per cent above normal, and for the compound exciter, 17.2 kv. or approximately 25 per cent above normal. This shows very clearly the effectiveness of the regulator with the wheatstone bridge arrangement because with no regulator the alternator voltage would have reached 180 per cent of normal value when tripping the

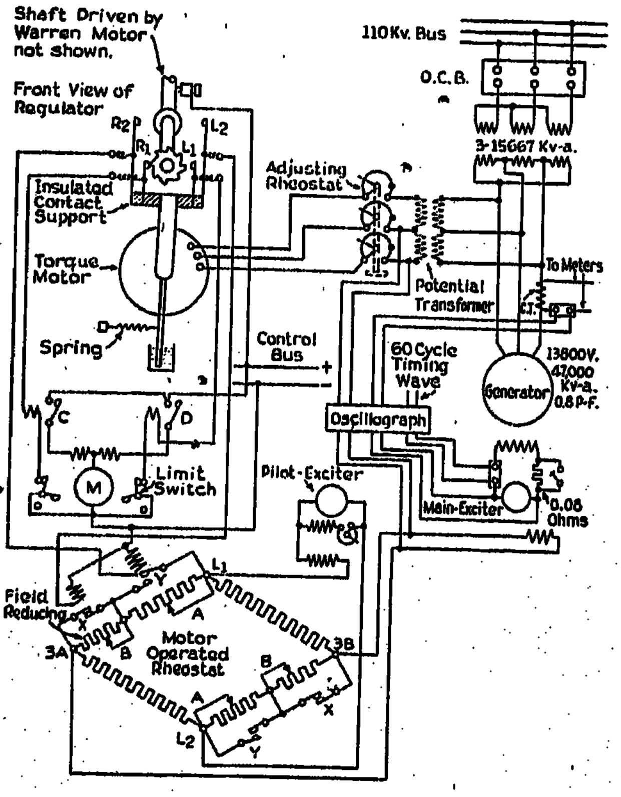

Fig. 1. Connections for tests at Spier Falls station

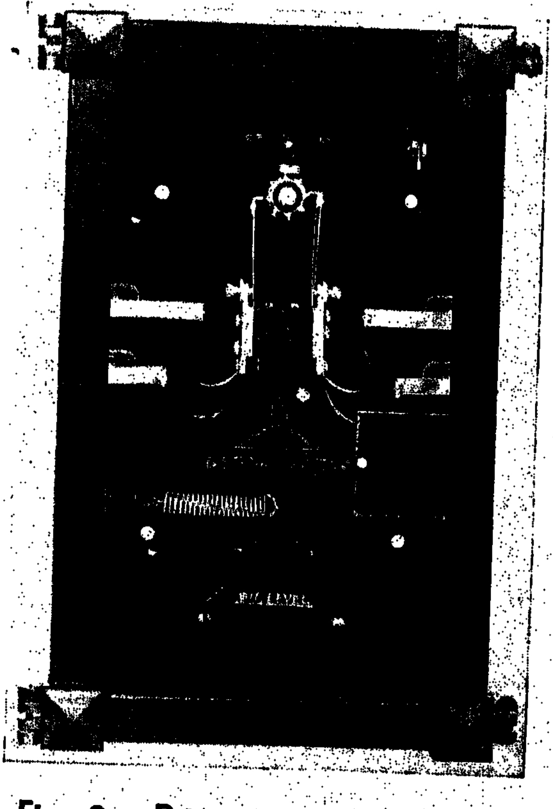

Fig. 2. Primary control element of high speed regulator

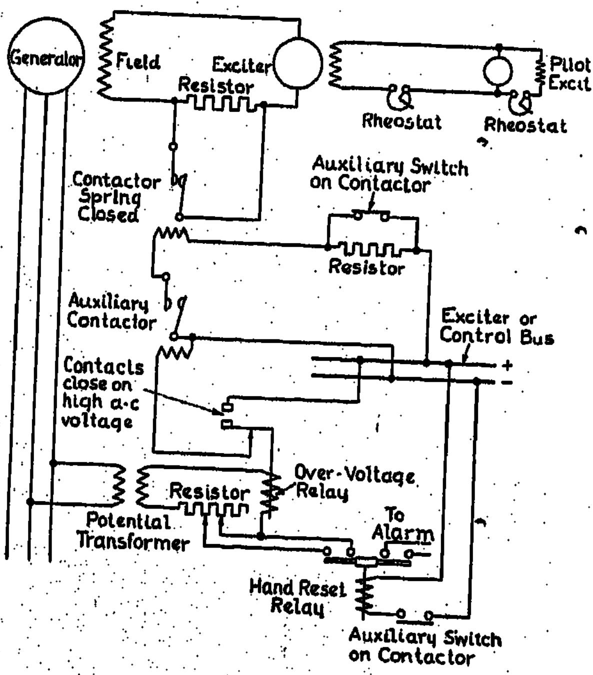

Fig. 3. Method of automatically inserting resistance in alternator field circuit upon occurrence of overvoltage

transformer high voltage circuit breaker and dropping a 40,000-kw. load of 0.9-power factor. Without the effect of transformer magnetizing current as would be the case if load were tripped on the low voltage side of the transformer, the alternator voltage would reach double value with no regulator or voltage limiting means.

What may be accomplished in limiting alternator voltage by automatically inserting resistance of 1.12 ohms in the alternator field circuit when dropping a 40,000-kw. load of 0.9-power factor is shown in Fig. 6. In this test the overvoltage relay shown in Fig. 3 was set to operate at 16.8 kv., and it held this value. It may be noticed that the maximum alternator voltage reached was 17.7 kv., or approximately 128 per cent of normal. In attempting to hold a-c. voltage the overvoltage relay opened and closed the contactor connected across the 1.12-ohm resistor in the alternator field circuit, giving the sudden increases and decreases in alternator voltage. This operation continued until the regulator could gain control, and lower the a-c. voltage to a point where the overvoltage relay would not operate. This was accomplished at the end of approximately 10 sec., as shown by a high speed voltage chart record. At that point, the regulator, which had been doing all it could to reduce the excitation, finally gained control and brought the voltage back to normal in about another 5 sec. The rather long time which elapsed before the regulator gained control was due to the use of a series rheostat instead of the wheatstone bridge arrangement.

## Conclusions

The tests described indicate that a suitable regulator and wheatstone bridge type of exciter field rheostat set to give zero or slightly negative main exciter armature voltage provide a simple means of limiting overvoltage caused by dropping load. Under ordinary conditions such equipment functions as required to hold normal a-c. voltage, but at the same time is ready to prevent the voltage from reaching dangerous values which would overstress the insulation of generators and connected apparatus. Furthermore, the use of such equipment has made possible the design of lightning arresters and protective apparatus to give better protection and at the same time not be subject to failure on overdynamic voltage.

The alternative method of automatically inserting resistance in the alternator field circuit also is very effective in keeping the a-c. voltage within desired limits when load is lost. Therefore, this method is available for use where overvoltage protection is needed and there are no generator voltage regulators; or where regulators are being used, but the excitation system is of the older type and it is neither desirable nor economical to change the exciter field circuit to include such equipment as the wheatstone bridge.

In the tests described, load was dropped by tripping the transformer high voltage circuit breaker and therefore the effect of line charging current was not included. The effect of charging current is to give a higher value

of voltage, the amount varying with the length and voltage of the line and the number of generators and transformers connected after load is lost.

Curve $A^1$ in Fig. 4 shows that it is possible to calculate very closely the overvoltage on generators caused by the dropping of load. The method of this calculation is described in the companion article immediately following.

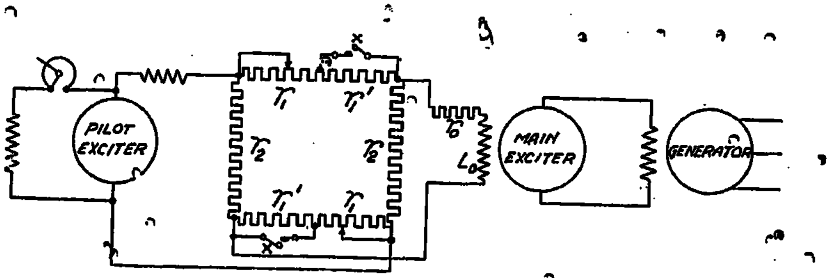

Fig. 1. Schematic diagram of excitation circuits using wheatstone bridge type rheostat

# Calculation of Generator Overvoltage

**Following the sudden loss of load by an alternator, speed and terminal voltage tend to increase rapidly. In the following article, a method is outlined for predetermining such overvoltage, with especial reference to waterwheel generators. Test results which have been obtained on an actual machine prove that the curve of overvoltage which may be calculated by this method closely follows that secured in practise.**

By
**J. W. BUTLER**
Associate A.I.E.E.
General Electric Co.,
Schenectady, N. Y.

CALCULATION of dynamic overvoltage of alternators following the sudden dropping of load is a subject that as yet has not been covered very extensively. The predetermination of the extent of such overvoltage is very desirable, however, in that it enables the necessary precautions to be taken to guard against the disadvantages which may result from voltages greater than normal. These may be especially serious in waterwheel generators. The method of calculation outlined applied especially to this type of unit, and allows the alternator terminal voltage to be expressed in terms of time subsequent to the loss of load. Test results which have been obtained on a 37,500-kw. machine prove the accuracy of the calculated results.

The factors influencing this type of overvoltage are overspeeding of the units, and the action of the generator voltage regulators. The major portion of overvoltage subsequent to loss of load is contributed by the increase in speed of the generator itself rather than by the increase in excitation due to overspeeding of the exciters. As a result, simplifying assumptions may be made relative to the exciter characteristics without appreciably affecting the accuracy. Assumptions used in this article and applying to the pilot exciter are as follows:

1. The time constant of the pilot exciter shunt field is so small as compared to the equivalent time constant of the speed-time curve that the shunt field current follows the speed exactly.
2. The load saturation curve of the pilot exciter coincides with the no-load saturation over the operating range. This is approximately true for pilot exciters that are flat-compounded and liberally designed.

Assumptions applying to the main exciter are:

1. Shunt wound main exciters will be considered, as shunt windings are generally believed to have the better characteristics and are commonly used at the present time.
2. The inductance of main exciter field circuit remains constant, but is corrected by a factor, depending upon the type of field structure.
3. The open circuit instead of the load saturation curve of the main exciter is used.

These last two assumptions compensate in a measure for the effect of the voltage coming down on a higher curve than the saturation curve, due to eddy currents when the field current decreases rapidly.

Heaviside's operational calculus is used in the analysis. The multiplier 1 appearing in the operational form of eqs. 1, 2, 4, 6, and 7, is called Heaviside's unit function. It is used in the derivations of his formulas, and even if it is not written down, it is tacitly assumed to be present. Generally speaking, it means that the action begins at $t = 0$ and time cannot be counted backward; that is, negative values of time cannot be used. The symbol $p$ is the Heaviside operator, which replaces $\frac{d}{dt}$ wherever it appears in the differential equations. An explanation of these terms as well as the steps involved in solving these differential equations to obtain eqs. 3, 5, and 8, is given in various texts. "Operational Circuit Analysis" by V. Bush, and "Heaviside's Operational Calculus" by E. J. Berg are especially recommended. However, if it is desired to work out a particular problem without going into it deeply, eqs. 3, 5, and 8 may be used without studying either their origin or Heaviside's operational calculus.

---

Especially written for ELECTRICAL ENGINEERING and including the information given in the appendix to "Overvoltage on Transmission System Caused by Dropping Load" (No. 31-140) presented at the A.I.E.E. South West District meeting, Kansas City, Mo., Oct. 22-24, 1931.

### PILOT EXCITER ARMATURE VOLTAGE

With the assumptions previously outlined, the curve of pilot exciter armature voltage readily may be obtained as follows: From the saturation curve of the pilot exciter at normal speed, saturation curves for 110-per cent, 120-per cent, etc., speed may be drawn. Then drawing in the $RI$ line (product of field resistance and field current) as indicated on Fig. 2, the voltage for each speed is read as the intersection of the $RI$ line and the saturation curve for the particular speed.

A curve ordinarily may be obtained from the water-wheel manufacturer giving the speed of the unit upon sudden loss of load as a function of time; hence, by using the values of voltage for different speeds in conjunction with this speed-time curve, a voltage-time curve may be drawn. An empirical expression for this pilot exciter voltage-time curve in operational form using one exponential is

$$e_1 = a + \frac{b-a}{T_1p+1}\,1 \qquad (1)$$

where

$a$ = initial value of voltage

$b$ = final value of voltage

$$p = \frac{d}{dt}$$

and

$$\text{the time constant } T_1 = \frac{t_o}{\log_\epsilon \dfrac{b-a}{b-e_o}}$$

$e_o$ and $t_o$ are the coordinates of a particular point on the curve. It is preferable to take a point in the region where the greatest accuracy is desired.

### MAIN EXCITER FIELD CURRENT

The next step is to determine the main exciter field current considering regulator action on the bridge rheostat, and overspeeding of the pilot exciter. The excitation circuits, employing the wheatstone bridge type rheostat, are shown on Fig. 1. The method will be developed for this type of rheostat, but it is obvious that the method of attack would be the same for other types of control. The application and operation of the bridge type of rheostat are described in the companion article "Generator Overvoltage When Dropping Load" by E.J. Burnham, immediately preceding.

e voltage $e_1$ operates upon the bridge circuit, in $r_o$ and $L_o$ are the shunt field resistance and inducrespectively and $r_1$, $r_1'$ and $r_2$ are the rheostat re- Upon indication of overvoltage, the regulator cts $x$ inserting both blocks of $r_1'$ in the cir- alue of $r_1'$ usually is sufficient to reverse the

Consider the case when the regulator fails to operate. The current through the main exciter field will be

$$i_o = \frac{a\,(r_2-r_1)}{2\,r_1r_2 + r_o\,(r_2+r_1)} + \frac{r_2-r_1}{2\,r_1r_2 + (r_o+pL_o)(r_2+r_1)} \times \frac{b-a}{T_1p+1}\,1 \qquad (2)$$

The solution of which is

$$i_o = \frac{a}{m} + \frac{b-a}{nT_1}\,(A_o + A_1\epsilon^{-a_1t} + A_2\epsilon^{-a_2t}) \qquad (3)$$

where

$$m = \frac{2\,r_1r_2 + r_o\,(r_2+r_1)}{r_2-r_1} \qquad n = \frac{L_o\,(r_2+r_1)}{r_2-r_1}$$

$$A_o = \frac{1}{a_1a_2}$$

$$A_1 = \frac{1}{-a_1\,(a_2-a_1)} \qquad a_1 = \frac{m}{n}$$

$$A_2 = \frac{1}{-a_2\,(a_1-a_2)} \qquad a_2 = \frac{1}{T_1}$$

The contacts $x$ are opened by a voltage regulator in 3 cycles after the indication of 5 per cent overvoltage. This overvoltage will appear the instant load is lost. Due to the quick action of the regulator and the time constants of the circuits involved, it can be assumed with very little error that the loss of load and opening of the contacts $x$ occur simultaneously.

Hence, the equation for the current after the regulator acts can be written

$$i_o = \frac{a\,(r_2-r_1)}{2\,r_1r_2 + r_o\,(r_2+r_1)} - 2\left[\frac{a\,(r_2+r_o)}{2\,r_2r_1 + r_o\,(r_2+r_1)} \times \frac{r_2r_1}{2\,r_2\,(r_1+r_1') + (r_o+pL_o)\,(r_2+r_1+r_1')}\right]1$$

$$+\frac{r_2-r_1-r_1'}{2\,r_2(r_1+r_1')+(r_o+pL_o)(r_2+r_1+r_1')} \times \frac{(b-a)}{T_1p+1}\,1$$

The solution being (4)

$$i_o = Y_1 + Y_2\epsilon^{-a_2t} + Y_3\epsilon^{-a_3} \qquad (5)$$

where

$$Y_1 = \frac{b\,(r_2-r_1-r_1')}{2\,r_2\,(r_1+r_1') + r_o\,(r_2+r_1+r_1')}$$

$$Y_2 = \frac{(r_2-r_1-r_1')\,(b-a)}{L_o\,(r_2+r_1+r_1')\,(a_2-a_3)}$$

$$Y_3 = \frac{(r_2-r_1-r_1')(b-a)}{[2\,r_2\,(r_1+r_1') + r_o\,(r_2+r_1+r_1')]\,[(T_1\,a_3-1)]} + \frac{2\,a\,(r_2+r_o)\,r_2r_1'}{[2r_2r_1+r_o(r_2+r_1)][2r_2(r_1+r_1')+r_o(r_2+r_1+r_1')]}$$

$$a_3 = \frac{2 r_2 (r_1 + r_1')}{L_o (r_2 + r_1 + r_1')} + \frac{r_o}{L_o}$$

$$a_2 = \frac{1}{T_1}$$

Thus eq. 5 gives main exciter field current considering regulator action on the bridge rheostat and overspeeding of the pilot exciter. This current flowing through the main exciter shunt field produces main exciter armature voltage and current which will now be considered.

## MAIN EXCITER ARMATURE VOLTAGE AND CURRENT

By plotting eq. 5, the curve of main exciter armature voltage can be determined, considering the increase in speed, as follows: For any particular value of $i_o$ flowing at time $t$ the voltage is read from the saturation curve (taken at normal speed). From the speed-time curve of the unit, the speed of the set can be read for the particular time $t$ chosen, and the voltage increased in direct ratio. The voltage function thus obtained is that which operates upon the generator field. The operational equation of such a curve, similar to that of eq. 1, is

$$E = E_o - \frac{E_1}{T_2 p - 1} 1 \qquad (6)$$

where

$E$ = main exciter armature voltage

$E_o$ = voltage before loss of load

$E_1$ = increase in main exciter armature voltage (final value minus the initial value $E_o$)

$T_2$ = time constant obtained from main exciter armature voltage-time curve

The problem now is to find an equation of generator field current as a function of time. Having this, generator terminal voltage for any value of field current can be read directly from the saturation curve and corrected for the increased speed at the particular time chosen.

There are two factors affecting the generator field current. Upon sudden loss of load, the field current drops immediately to a value necessary to produce flux back of transient reactance. It then builds up to a value that existed before loss of load, according to the open circuit time constant of the generator field circuit, and provided constant slipring voltage is maintained. But in this case under consideration, due to the regulator action and increased speed of exciters, the slipring voltage varies according to eq. 6.

With the voltage expressed by eq. 6 applied to the sliprings, and considering the drop of current at $t = 0$, the following type of equation for generator field current will result:

$$I = I_o - I_o' \frac{p}{T'_{do} p + 1} 1 + \frac{E_1}{r} \frac{1}{(T_2 p + 1)(T'_{do} p + 1)} 1 \qquad (7)$$

The solution being

$$I = I_o - I_o' \epsilon^{-c_1 t} + I_1 (C_o + C_1 \epsilon^{-c_1 t} + C_2 \epsilon^{-c_2 t}) \qquad (8)$$

where

$I_o$ = field current before loss of load

$I_1 = \frac{E_1}{r T_2 T'_{do}}$

$T'_{do}$ = open circuit time constant of generator

$r$ = resistance of field circuit

$I_o'$ = the decrease in field current the instant load is lost. This calculation is explained under the heading "Calculations for Instant of Dropping Load" following.

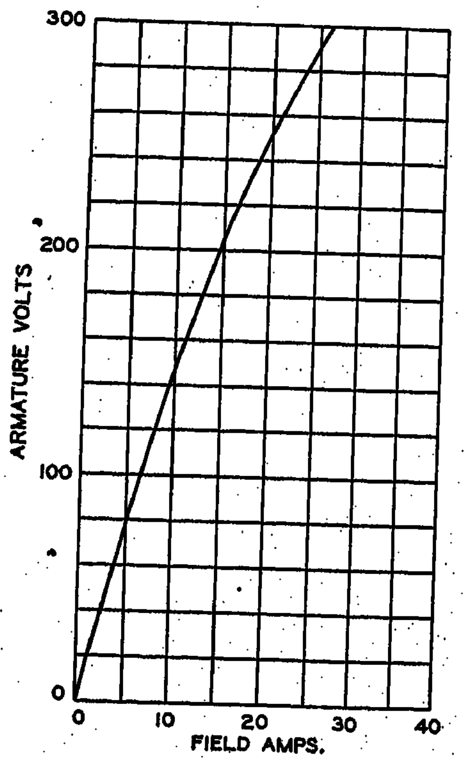

**Fig. 3.** Main-exciter saturation curve

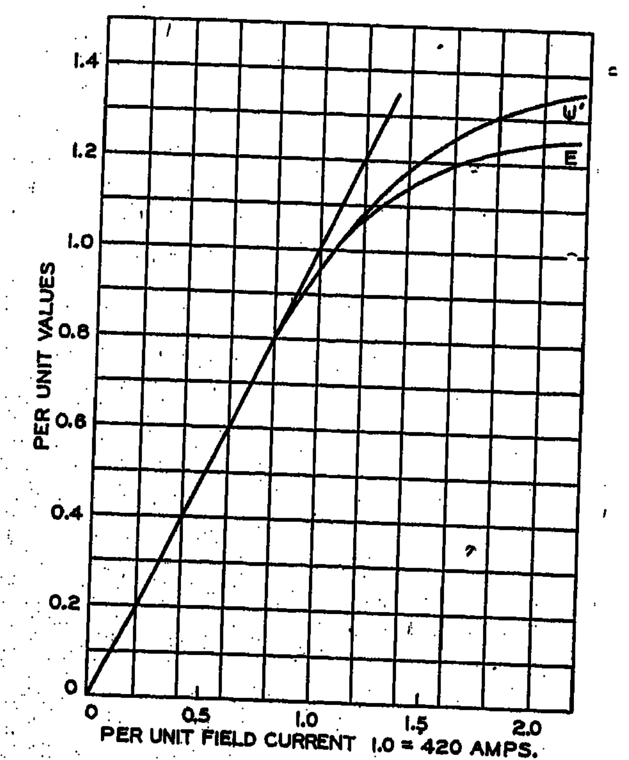

**Fig. 4.** Calculated linkage and voltage saturation curves of generator

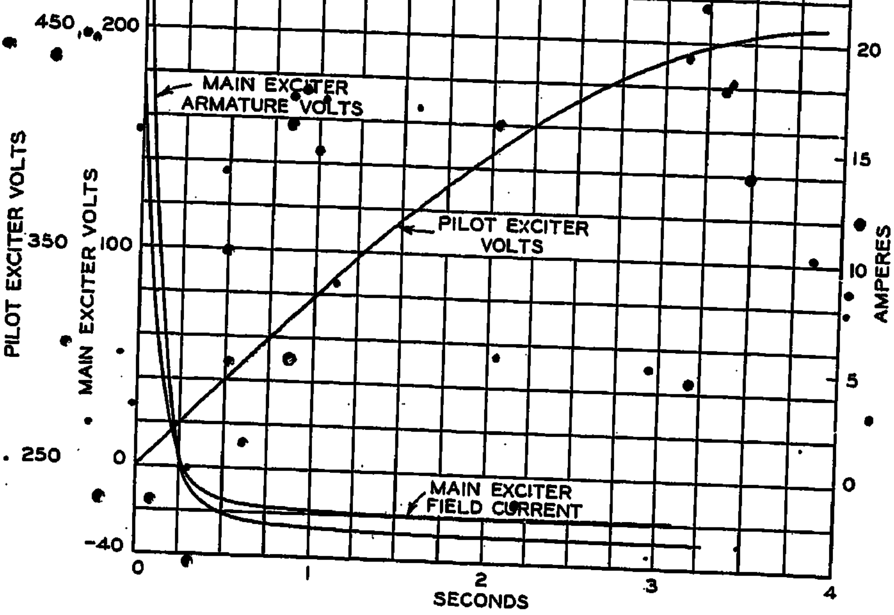

Fig. 5. **Exciter characteristics**

$$C_o = \frac{1}{c_1 c_2}$$

$$C_1 = \frac{1}{-c_1(c_2 - c_1)} \qquad c_1 = \frac{1}{T'_{do}}$$

$$C_2 = \frac{1}{-c_2(c_1 - c_2)} \qquad c_2 = \frac{1}{T_2}$$

After plotting eq. 8, the curve of generator terminal voltage can be determined by using the generator saturation curve and speed-time curve as was explained for main exciter armature voltage. This completes the calculation for conditions at the generator terminals. Although quite involved, and not covered in this article, the same method can be extended to include a long transmission line remaining connected after load is dropped.

### CALCULATION FOR INSTANT OF DROPPING LOAD

The calculation of generator field current drop and armature voltage rise the instant load is dropped, is given in "Synchronous Machines—III" by R.E. Doherty and C.A. Nickle, A.I.E.E. TRANS., V. 46, 1927, p. 1-18; and "Two Reaction Theory of Synchronous Machines" by R.H. Park, A.I.E.E. TRANS., V. 48, July 1929, p. 716-30. Extending these derivations to include pole leakage due to saturation, the total per unit field flux linkage under load is

$$\frac{x_{ad}}{-x'_d}\left[I - i_d(x_d - x'_d) + I_s\frac{x'_d - x_{ld}}{x_{ad}}\right] \qquad (9)$$

All quantities are in per unit values and defined as follows:

$x_{ad}$ = armature reaction reactance direct axis
$x_d$ = synchronous reactance direct axis
$x_q$ = synchronous reactance quadrature axis
$x'_d$ = transient reactance direct axis
$x_{ld}$ = armature leakage reactance direct axis
$i_d$ = $i \sin(\delta + \phi)$
$i$ = load current
$\delta$ = load angle
$\phi$ = power factor angle
$I$ = full load excitation neglecting saturation
$I_s$ = excitation due to saturation

During sudden changes of load, the quantity in the bracket of eq. 9 must remain constant. This may be denoted by $\Psi'$ as follows:

$$\Psi' = I - i_d(x_d - x'_d) + I_s\frac{x'_d - x_{ld}}{x_{ad}} \qquad (10)$$

A curve of $\Psi'$ and per unit field current can be plotted from the open circuit saturation curve of the machine. Then for a given load condition $\Psi'$ can be calculated, and when load is lost it remains constant the first instant; hence, from the curve of $\Psi'$ the per unit excitation the first instant can be obtained and the corresponding voltage read from the saturation curve.

The effect of amortisseur winding currents is neglected due to their fast time constant.

### NUMERICAL EXAMPLE

An application of the method described will be illustrated by calculations for a 37,500-kw., 0.8-power-factor generator. Actual tests were made on this machine and provide a check as to the accuracy of the method.

Generator constants:

$X_{ad}$ = 0.76 $X_{ld}$ = 0.27
$X_d$ = 1.03 $T'_{do}$ = 4.5 seconds
$X_q$ = 0.65 $r$ = 0.337 ohms (field circuit resistance)
$X'_d$ = 0.37 Saturation curve, Fig. 4

Main exciter constants:

$r_o$ = 4.32 ohms (shunt field resistance)
$L_o$ = 7 henrys (inductance of shunt field circuit)
Saturation curve, Fig. 3.

Pilot exciter:

Saturation curve, Fig. 2.
Bridge type rheostat constants:
$r_1$ = 4 $r_1'$ = 100 $r_2$ = 48 (refer Fig. 1)

By using the saturation curve of Fig. 2 for various speeds and the speed-time curve of Fig. 6, the pilot exciter voltage curve Fig. 5 is plotted. Eq. 1 then becomes

$$e_1 = 250 + \frac{210}{2p + 1}1$$

With the constants given for the rheostat and main exciter, eq. 5 becomes

$$i_o = -2.3 + 1.16\,\epsilon^{-0.5t} + 19.35\,\epsilon^{-10t}$$

The curve of $i_o$ is plotted as shown on Fig. 5. By using this, the speed-time curve of Fig. 6, and the saturation curve of Fig. 3, a curve of slipring (main exciter armature) voltage as a function of time is plotted as shown in Fig. 5. The operational equation, eq. 6, becomes

$$E = 265 + \frac{295}{0.165\,p + 1}\,1$$

Hence, eq. 8 becomes

$$I = 785 - I_o'\,\epsilon^{-t/4.5} - 1180\,(0.75 - 0.78\,\epsilon^{-0.22t} + 0.03\,\epsilon^{-6t})$$

It will now be shown how to calculate the value of $I_o'$. For the particular machine under consideration, eq. 10 becomes

$$\Psi' = I - i_d\,0.66 + 0.132\,I_s$$

The machine was delivering 40,000 kw. at 0.9 power factor and normal voltage, or 44,500 kva. when load was dropped. Hence, based on machine rating 0.94 per unit current was flowing.

For this condition

$$\delta + \phi = \tan^{-1}\frac{ix_q \sin = \phi}{\cos\phi}$$

$$\delta + \phi = 49 \text{ deg.}$$

Hence

$$i_d = 0.94 \sin 49 \text{ deg.}$$
$$= 0.71$$

$I$ is excitation neglecting saturation and is obtained as follows: Referring to Fig. 7

$$e_d = I = e_t \cos\theta + j\,(e_t \sin\theta + i_a x_d)$$
$$= 0.9 + j\,(0.435 + 0.97)$$
$$= 1.67$$

where

$e_d$ = per unit voltage back of synchronous reactance
$I$ = per unit field current to produce $e_d$
$e_t$ = per unit terminal voltage
$i_a$ = per unit armature current
$\theta$ = power factor angle

$I_s$ is excitation due to saturation and is obtained as follows. Referring again to Fig. 7

$$e_v = I' = e_t \cos\theta + j\,(e_t \sin\theta + i_a x_{ld})$$
$$= 0.9 + j\,(0.435 + 0.254)$$
$$= 1.13$$

where

$e_v$ = per unit voltage back of leakage reactance
$I'$ = per unit field current to produce $e_v$

Thus 1.13 is the per unit excitation necessary neglecting saturation; but from the saturation curve we find it takes 1.38 per unit excitation to get 1.13 per unit voltage, hence, $I_s = 0.25$ due to saturation. Therefore; the value of $\Psi$ becomes

$$\Psi = 1.67 + 0.71\,(0.66) + 0.132\,(0.25)$$
$$= 1.24$$

When the machine loses load, $i_d$ goes to zero and the first instant $\Psi'$ must remain constant. So we turn to the no-load curve of $\Psi'$ and find that the value of field current necessary to produce 1.24 $\Psi'$ is 1.58. Also, from the no-load saturation curve we find that 1.58 field current produces 1.18 voltage, the value obtained at $t = 0$.

On this particular machine, unit field current is 420 amperes (air-gap line, normal voltage). Hence, the value of field current the first instant is 663 amperes and $I_o'$ is 122 amperes.

Using this value of $I_o'$ and dividing through by 420 to change to per unit, we get for generator field current

$$I = (1.87 - 0.29\,\epsilon^{-0.22t}) - 2.8(0.75 - 0.78\,\epsilon^{-0.22t}) + 0.03\,\epsilon^{-6t})$$

Plotting this equation results in the current curve of Fig. 6 and using this with the open-circuit saturation curve of the generator and its speed-time curve, the generator terminal voltage is plotted as in Fig. 6. The results check with surprising accuracy, values obtained by test considering that there were four or five cycles of arcing in the breaker disconnecting the load and that calculated values of unsaturated machine constants were used.

# Tape Armored Telephone Toll Cable

Toll cables buried directly in the earth are coming into increased use. Such cables are not installed in the usual clay conduit but are protected by layers of paper, jute, and steel tapes. Complete equipment for laying this cable has been developed.

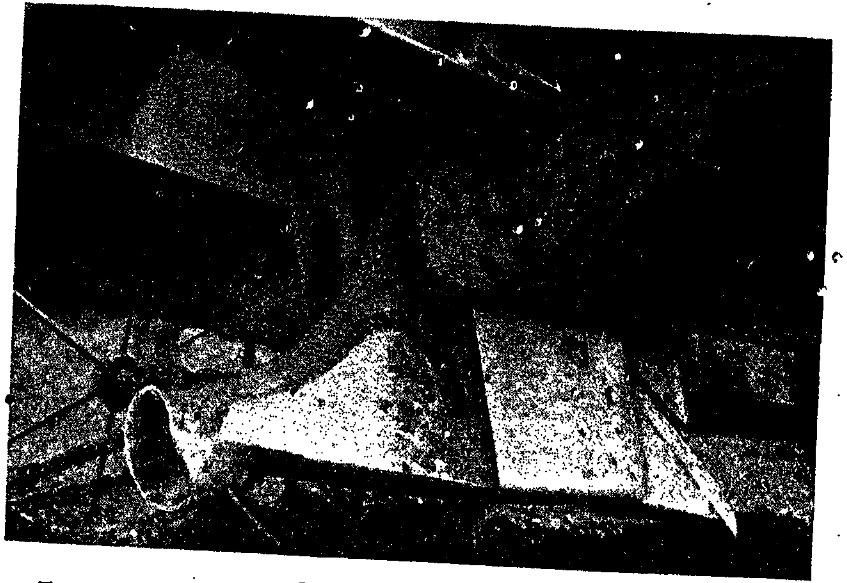

Fig. 1. Lower part of cable-laying plow and tube

TOLL CABLE in this country has in the past been installed either aerially on pole lines, or underground in clay conduit, depending largely upon the number of cable units needed to meet service requirements over a given period of time. Although there will continue to be definite fields for these two types of construction, there are many routes where ground conditions are favorable and on which one or two cables will serve all needs for a long period; it is for these cases that buried tape armored cables were developed.

The cable is termed "tape armored" because of its outer protection. Lead-sheath cable of the type ordinarily used for toll service is covered first with a wrapping of paper followed by two layers of jute roving. Two steel tapes, one over the other, then are applied, each tape being 2 inches wide and 41 mils thick. A separation of one-half inch is maintained between adjacent turns of the tape, and the outer layer is so placed that it covers the space left between the windings of the inner layer. Two wrappings of jute cover the tape. The lead sheath, paper, jute, and steel tapes are thoroughly coated with an asphalt compound; to prevent adjacent layers from sticking together on the cable reels the completed cable is given a coat of whitewash. Such a cable of so-called full size has a diameter of 3¼ in. and a weight of 11.3 lb. per ft. as compared with 2⅝-in. diameter and 8-lb. weight of unarmored cable.

Buried tape armored cables possess several advantages over cables carried on pole line or in underground conduit:

1. Easements for buried tape armored cable on private rights-of-way may sometimes be obtained more cheaply than for pole lines, as the use of the land for ordinary agricultural activities is not disturbed.

2. Induced currents from paralleling power lines are appreciably less than in unarmored aerial or underground cables, due to the shielding effect of the steel tapes. This factor is discussed in "Trends in Telephone and Power Practise as Affecting Coordination," by W. H. Harrison and A. E. Silver, A.I.E.E. TRANSACTIONS, June 1931, p. 437-447.

3. Cable may be laid to follow the contour of rough country and have sharp bends to avoid obstructions, while conduit must have a fairly even grade and long radius curves to permit cable being pulled through it.

4. Manholes are required at spacings of from 500 to 700 ft. if conduit is provided, while with tape armored cables, manholes may be omitted except at loading points which normally occur at 6,000-ft. intervals.

On the other hand, as tape armored cables are buried directly in the earth, the location and repair of troubles are generally more difficult and expensive than for aerial cables. However, improvements in methods for maintaining buried cables should reduce such costs, and in any event, the amount of trouble per cable mile reasonably may be expected to be much less than on aerial cables because of their security from fire, storm, and bullets.

The question of the best possible location for buried cable is one requiring careful consideration. It is thought that right-of-way on private property generally is more desirable than on public highways where road improvements are liable to necessitate expensive cable relocation. On the other hand, the difficulty of obtaining private property easements at a reasonable price, or high construction costs on privately owned land, may make it advisable to place the cable on the highway and so locate it as to subject it to the least probability of having to be moved.

Although with fairly open country, frequent roads, and adequate maps, ordinarily there would be no necessity for a preliminary aerial survey, the first tape armored toll cable in this country was installed by the Southwestern Bell Telephone Company between Fort Worth and Cisco, Texas, in country which made it advisable to photograph the general route from an airplane. The topography for 85 miles of the total 100 miles on this route is extremely rugged, with large quantities of rock in the soil and the ground covered with dense growths of scrub oak and other underbrush. Roads are few and accurate maps were not obtainable. However, the aerial photographs enabled the tentative route to be marked out easily and was of assistance in

---

Based upon "Tape Armored Telephone Toll Cable" (No. 31-134) presented at the A.I.E.E. South West District meeting, Kansas City, Mo., October 22-24, 1931.

expediting the ground survey which is of course necessary in any event.

As the Fort Worth-Cisco and other tape armored cables later installed are largely on private rights-of-way, in many instances in cultivated fields, special tractors of the caterpillar type had to be designed to transport the 5-ton cable reels over soft and often muddy ground. There have been also some developments of four-wheel-drive truck equipment for handling deliveries on the right-of-way as well as on the highway.

The equipment for digging the trench, laying the cable, and making the backfill has changed considerably since the early design. For trenching in earth, a commercial wheel type excavating machine was first used and proved quite satisfactory until soil containing a considerable quantity of rock was encountered. A rock-breaking plow then was designed, and answered the needs quite satisfactorily except in cases where solid rock was encountered and pneumatic drills and blasting were required. The cable was laid in the trench directly from the reel, except in such cases as crossing under paved highways and pipe lines, or on steep slopes, where the cable was pulled over rollers placed on the bottom of the trench. Backfilling was accomplished by a separate machine of the type commonly used for filling trenches by scraping the upturned dirt back into the trench.

The use of the rock-breaking plow focused attention on the further possibility of combining the equipment. This led to the development of the outfit shown in Fig. 2 which not only digs the trench but also lays the cable and then fills the excavation, all in one operation. The equipment consists essentially of two main parts, a chassis, and a vertical central portion which may be raised or lowered to bury the cable at depths up to 28 inches. Properly speaking the plow of this equipment does not dig a trench, but merely cuts a slot into the ground. Some earth is thrown out and after the cable is laid this is drawn to the center of the slot by the backfiller. If desired, a tractor may be run over the disturbed earth to pack it down.

Two tractors, sometimes three, are required to pull the cable-reel trailer, plow, and backfiller. The essential features of the plow and cable-laying tube are shown in Fig. 1. The forward or cutting end is a steel plate having a sharpened edge and a shoe provided at the bottom to make a larger space for the cable. Side plates are welded to the cutting blade and to the outer sides of the tube through which the cable passes. The cable enters this tube directly from the reel, and as the pipe extends into the ground, the cable is deposited at the bottom of the trench and is not dragged through the ground at any time. After laying more than 300 miles of cable, this plow is still in good condition.

Small boulders and tree roots often made progress very difficult for the cable-laying plow and it was found that with a narrow slot first cut into the earth, the usual plowing and cable laying operations were considerably expedited. The plow used for this purpose is called a rooter plow as shown in Fig. 3. It is of rugged design and fits the same chassis as the cable-laying plow so that either attachment may be used interchangeably.

The lead sleeve covering the cable splice necessary every 750 ft. was at first protected by a cast iron case. This covering was found to be rather expensive and it was felt that a cheaper protection consisting of a wood case made of 2-in. creosoted yellow pine lumber would serve equally well. Space for branch cables is provided by two openings in one of the end pieces. The exposed lead sheath and sleeve within the case are painted with an asphaltum compound and covered with three layers of muslin tape which also is painted with the compound. The loading manholes for tape armored cables also are of 2-in. creosoted yellow pine. After the top is placed, it is covered with earth, the depth from the surface to the top of the manhole being at least 18 inches. This is necessary as it is desirable not to interfere with the use of the land for ordinary agricultural purposes. The type of manhole illustrated in Fig. 4 costs less than one-third that of the most economically built concrete manhole of similar dimensions. Markers

ig. 2. Complete cable-laying quipment of improved design, consisting of tractors, chassis for cable eel, cable-laying plow and tube, nd backfiller

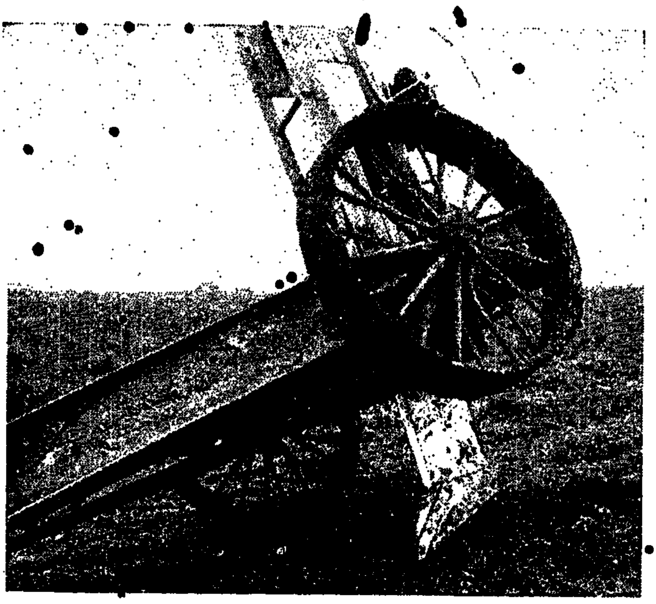

Fig. 3. (Left) Rooter plow which may be placed in the chassis, for cutting a preliminary slot in difficult ground containing tree roots and small boulders

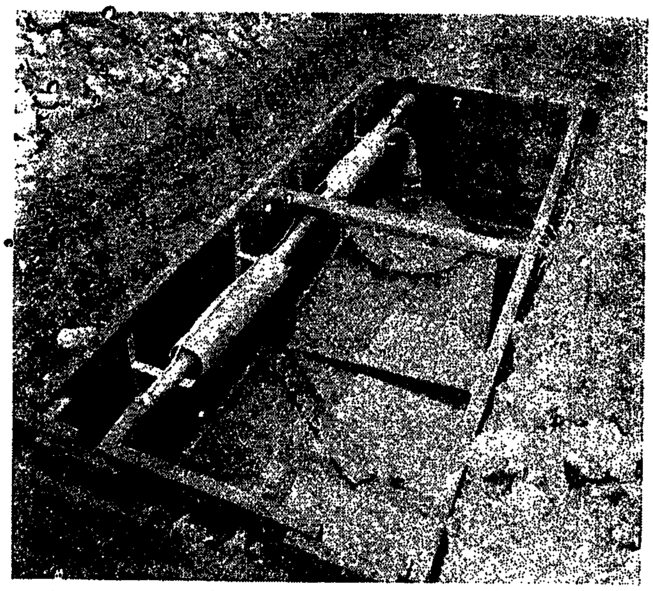
Fig. 4. (Right) Wood manhole. No floor is provided, the loading coil pots being buried in the earth



usually are provided at each manhole and at points along the cable route to enable the ready location of trouble, and the placing of additional loading coils or a future cable. To prevent damage by other excavating activities, warning signs are placed on each side of a road under which cable is laid, at pipe lines and railroad crossings, and at similar locations.

Electrical tests on tape armored cables do not differ appreciably from those used for unarmored cables. It is estimated that the minimum number of tests normally required is 5,150 individual measurements per mile of cable, and if conditions difficult of correction are encountered, many of the tests must be repeated. For the cables between St. Louis and Dallas, the estimated minimum number of individual test measurements reaches the rather astounding total of 4,500,000.

Since troubles in buried cables may be more difficult to locate and clear than for those on pole lines or in clay conduits, it is desirable that tape armored cable, when first placed, be as free as possible from defects which are likely to allow moisture to enter. The lead sheath is tested with nitrogen under pressure, at the factory, upon arrival at the destination, just before the cable is laid or plowed in, one or two days later, and then, before the splicing operations begin. As splicing necessitates the removal of the sheath at each end of a length of cable, most of the gas is lost. Nitrogen again is introduced upon completion of splicing in one loading section, 6,000 ft., and is allowed to remain for about two days. If no leaks are found, the loading coils are spliced in, and the loading splices tested with gas. Gage readings are taken and recorded during all these tests.

A discussion of the application of gas pressure testing for the detection of sheath breaks during installation and with the cable in service has been given by B. S. Wagner and A. C. Burroway in "Recent Developments in Telephone Construction Practises," A.I.E.E. TRANSACTIONS, July 1929, p. 836-848. In connection with constant gas-pressure testing on completed cables, however, two recent improvements seem worthy of mention here. First, the combined contactor-terminal which is compact, gas-tight, may be mounted either in a manhole or on a post, and is so constructed that the contactor may be replaced very easily. The second is an improved alarm circuit that avoids a difficulty possible in the earlier circuits; namely, the operation of any one contactor will render the alarm circuit insensitive to the subsequent operation of any other contactor in the 50-mile cable section until the first contactor is disconnected or the gas pressure is raised in the cable section it covers. This difficulty, resulting from the fact that a single alarm circuit is used for an entire repeater section of cable, is avoided by the plan shown in Fig. 5, based on the wheatstone bridge principle. Contactors at various points of the cable pair operate on reduced gas pressure and they short circuit given values of resistance. Equal values of resistance are located in the bridge at the repeater station. As each pair of resistances has a different value, the attendant at the repeater station merely inserts a non-metallic plug in each jack in turn until the correct one is found as evidenced by silencing of the alarm. The bridge then is rebalanced and remains so until another contactor operates.

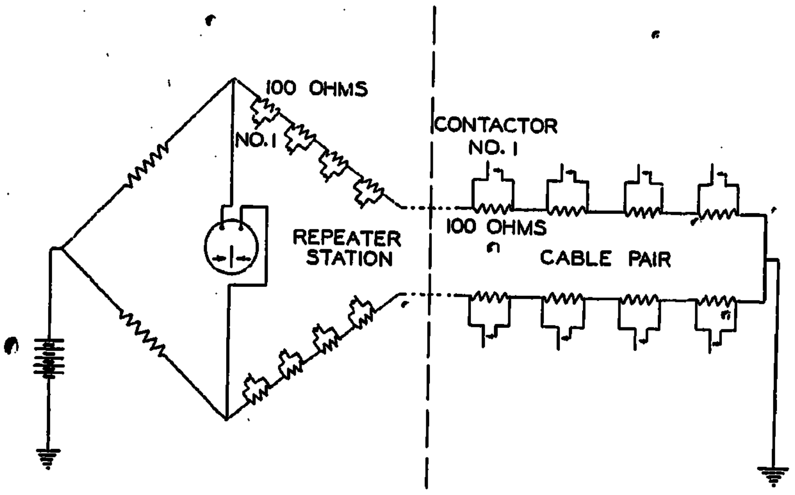


Fig. 5. Circuit of improved gas pressure alarm

To protect the cables during periods when the gas alarm is inoperative, as, for example, when a large sheath break or repair operation may permit practically all the gas to escape from a plug section, another maintenance device known as the low insulation resistance alarm is often used. This operates when moisture entering the cable lowers the insulation resistance between the conductors and the cable sheath. A number of pairs in the outer layer adjacent to the lead sheath is connected to a relay mechanism in the repeater station which automatically and in regular sequence switches these conductors to a sensitive insulation measuring device. A decrease in the resistance below a predetermined value causes an alarm to operate, and wheatstone bridge measurements then are made to locate the trouble The exceedingly small currents flowing through the moistened insulation are amplified by vacuum tubes sufficiently to operate the alarm.

No direct comparisons are available on which to base the relative costs of aerial and buried tape armored cables. However, it appears that one aerial cable on a pole line costs about 90 per cent of that of one buried tape armored cable, and two aerial cables on a pole line would cost about 85 per cent that of two buried tape armored cables. However, certain developments now under consideration promise a rather substantial reduction in the cost of buried cable and if these prove successful, it is quite probable that buried plant may cost even less than aerial cable.

There is another factor difficult of evaluation and that is the effect of service interruptions. Continuous and dependable service is one of the principal objectives of a telephone company and service failures are not only annoying to patrons but result in loss of revenue to the company. As previously discussed, it would seem that buried cable should be subject to less damage from external sources than aerial construction. If this is borne out by further experience, the use of buried cable may become more extensive.

# Paralleling Rotor and Stator

**A wound rotor induction machine may be given special characteristics by connecting the stator and rotor windings in parallel, either directly or through an auto-transformer. Pull-out torque, hp. output, and efficiency at large loads are increased for motor operation; and maximum kva. output is increased for operation as an induction generator.**

WOUND ROTOR induction motors normally are operated with the sliprings short-circuited. However, both rotor and stator may be independently magnetized thus permitting power to be taken or delivered through any one or two of the three channels, namely, the stator, rotor, and shaft. Further, the stator and rotor voltage and frequency can be adjusted to the same values, making it possible to parallel the stator and rotor. The advantages which have been found for such a scheme are as follows:

1. The breakdown torque of the machine operating as a motor can be approximately doubled, increasing the rating of a given motor.
2. Generator capacity and maximum output can be increased.
3. Higher efficiencies may be secured at large loads.

## STARTING AND OPERATION

The principle of operation of the motor is indicated in Fig. 1. With the switch $S_1$ open, the stator is supplied from the three-phase line, and the rotor is connected to the armature of a synchronous generator. The latter serves as a path for the secondary current, allowing the induction motor to be started and operate much the same as if the rings were short-circuited. If the stator phase rotation is 1-2-3, the voltages induced in the rotor will be of low frequency with a phase rotation of *a-b-c*, causing current to flow in the synchronous machine armature in the order *A-B-C*. The induction motor will rotate in a clockwise direction.

With the stator disconnected from the supply and short-circuited directly or through transformers, and power supplied to the rotor from the alternator, the induction machine may be started again. If the phase rotation of

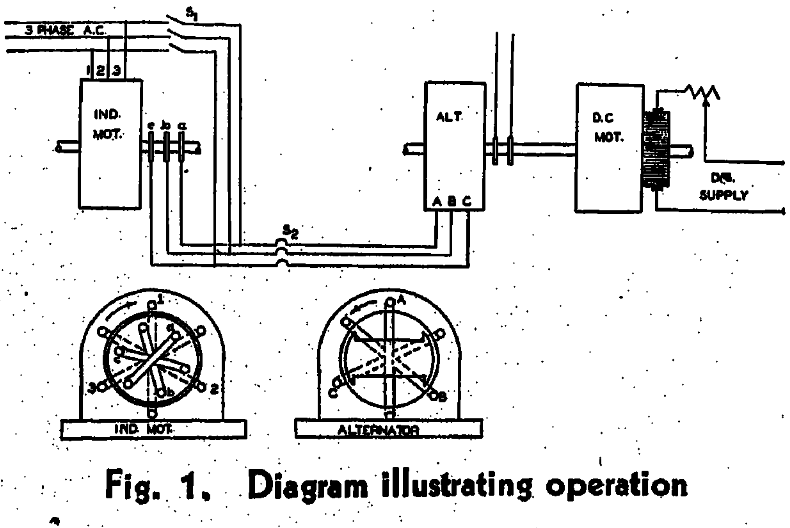

Fig. 1. Diagram illustrating operation

Based upon "An Induction Motor with Paralleled Rotor and Stator" (No. 32-27) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25-29, 1932.

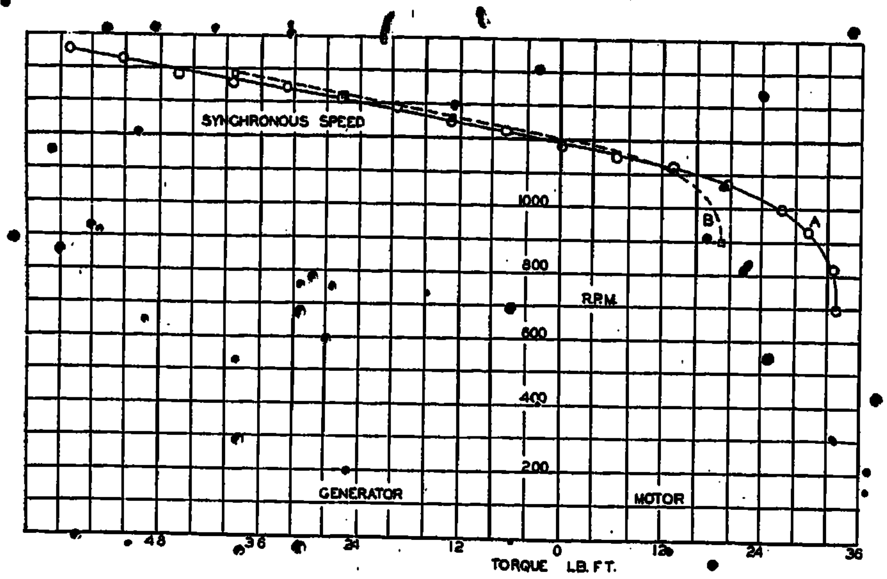

Fig. 2. Speed-torque curves of machine

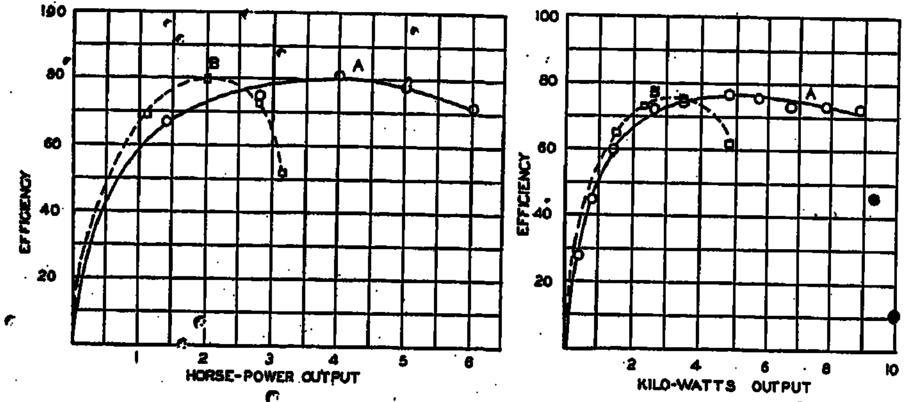
Curve A—Rotor and stator paralleled
Curve B—Rotor short-circuited



Figs. 3 and 4. Efficiency as a motor (left), and as a generator (right)

Curve A—Rotor and stator paralleled
Curve B—Rotor short-circuited

the alternator is *C-B-A* the induction machine will rotate in the same direction as above, and the low-frequency currents in the stator will be in the direction 3-2-1.

If the stator now is connected to the line in the usual manner, and at the same time the rotor continues to be supplied from the alternator with phase rotation *C-B-A*, the supply transformers will act as a low impedance path for the slip-frequency currents in the stator and the alternator will complete the path for the slip-frequency currents of the rotor. The magnitude of the voltage impressed on the rotor is dependent upon the field excitation of the synchronous machine. The frequency of the voltage depends upon the speed of the synchronous machine. By adjusting these two factors, the rotor and stator can be made to have the same voltage and frequency so that they can be synchronized and electrically connected through switch $S_1$. Switch $S_2$ now can be opened and the induction motor will continue to operate, both stator and rotor receiving power from the line. Rotation will be less than synchronous speed; the high frequency current in the stator will be in the order 1-2-3, and the low frequency currents in the order of 3-2-1. The high frequency currents in the rotor will be in the order of *c-b-a* and the low frequency current in the order of *a-b-c*. The machine when so connected has characteristics similar to those of the normal induction motor. When loaded the speed decreases slightly. When driven above synchronous speed the machine acts as an induction generator; the low-frequency currents in the stator and rotor are opposite in phase rotation to what they are as a motor.

The characteristics of the motor with its rotor and stator paralleled can be determined by applying ordinary induction motor theory. Using slip as parameter it is possible to determine the torque, stator copper loss, rotor loss, etc., by the power fed into the stator and for the same slip determine values for the same items which are produced by the power fed into the rotor.

## EXPERIMENTAL INVESTIGATIONS

Calculations and analysis of operation were checked experimentally. The machine selected for tests was a wound-rotor induction motor rated 10 hp., 60 cycles, three-phase, 1,140 r.p.m., 220-volt stator, 206-volt rotor. The motor had nearly a 1 to 1 ratio of stator to rotor turns. In order to keep within the limitations of the laboratory circuits, the voltage on each phase was dropped to 110 volts, 60 cycles, and the characteristics were determined with stator and rotor paralleled. In this machine the voltage supplied to each phase is a fundamental voltage, while the current will contain not only a fundamental component but also a low-frequency component. The results of these tests are shown as curve *A* in Figs. 2 to 5. For comparison, curve *B* in each figure shows the characteristics of the motor with normal connections.

As indicated in these figures, the breakdown torque of the motor can be approximately doubled by using the stator and rotor in parallel; likewise that the generator capacity and maximum output can be increased by the parallel connection. With the parallel connection, high efficiencies are obtained for large loads on account of reduced copper losses per unit output. However, the efficiencies are low for light loads because of larger iron losses and copper losses produced by the additional exciting current, the maximum efficiency for the two cases can be seen to be approximately the same for either the condition of motor or generator operation. The curves of Fig. 5 for generator operation show that the phase current with the parallel connection will be less than the phase current with the rotor short-circuited.

The circle diagram of the motor when the rings are short-circuited is indicated in Fig. 6. The no-load losses for this machine are very small but it can be seen that when the rotor and stator are paralleled the no-load line current contains a larger power component. This is because of the increased iron losses due to the high-frequency rotor flux and also the superposition of the two fluxes traveling in the iron at different speeds. In addition to this the exciting current in the rotor causes copper losses which increase the no-load input.

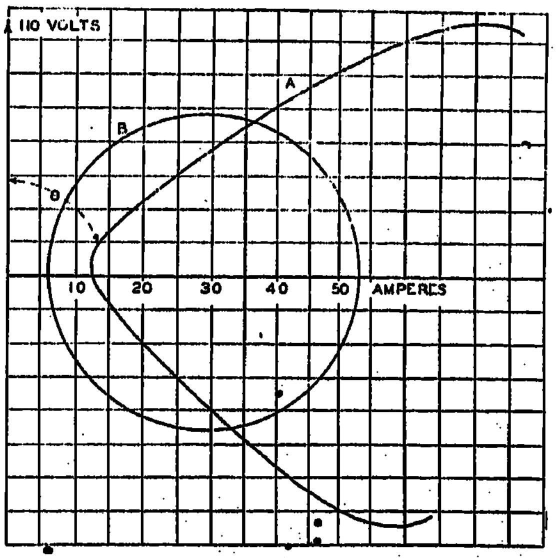

**Fig. 6. Locus of line current**

Curve A—Rotor and stator paralleled
Curve B—Rotor short-circuited

It will be noted also that the maximum power component of the input current is a little less than twice the maximum power component of the motor when its rings are short-circuited. This is caused by a slight terminal voltage drop with these heavy loads. It may be assumed that the heart-shaped diagram would have had a slightly higher maximum power component if the voltage had remained constant. The arithmetic sum of stator and rotor currents was almost equal to the line current.

The exciting current taken by the motor is indicated by the oscillogram of Fig. 7. It can be seen in Fig. 8 that some of the high frequency waves have pointed peaks and the other maximum values of the same wave have rounded points. This indicates a high saturation during part of the cycle.

When the machine is loaded, the high frequency currents and the low frequency currents are each slightly out of phase. This is caused by different constants in the rotor from those in the stator; *i. e.*, the ratio of stator inductance to stator resistance is different than the ratio of rotor inductance to rotor resistance. It also can be seen in Fig. 8 that the low frequency current is slightly less than the high frequency current in the same phase.

The effect of the low frequency currents upon the line will depend to a certain extent upon the ratio of the motor rating to the rating of the transformers supplying the load. It is obvious that if this ratio is large, the efficiency might be reduced.

It is possible to operate a wound rotor induction motor with its rotor and stator paralleled when the voltage ratio is not 1 to 1, by connecting the low voltage rotor to the high voltage line through an autotransformer. The behavior of the machine under these conditions should be better than when no transformer is used, since the transformer will by-pass part of the low frequency current that ordinarily would flow through the supply transformers

The tests made on the machine as a motor and as a generator indicated two disadvantages of the parallel connection; the machine was noisy and the exciting current was high. This noise might be eliminated by special designing. Also due to the superimposed fluxes rotating in opposite directions the iron of the motor was saturated; this difficulty could be minimized by a special design.

Variations in the rotor and stator constants and in external resistances permit a number of combinations of motor characteristics to be obtained, including both high starting torque and good regulation. Also if the machine is to be subjected to a wide range of load, maximum efficiency may be obtained by the use of a switching arrangement in the rotor that will short-circuit the rings when the load is light, and connect the rotor and stator in parallel when the load is heavy.

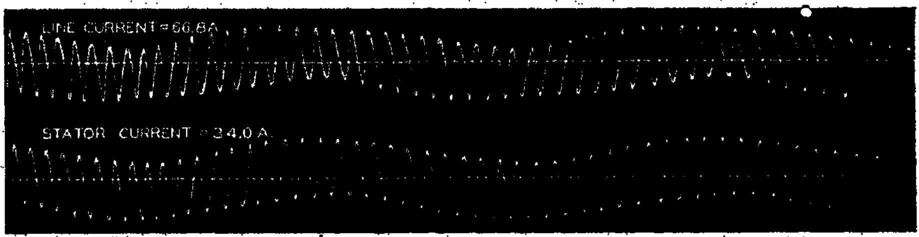

**Fig. 8. Full-load current with rotor and stator paralleled 220 volts applied**

# Interconnection of Electric Power Systems

**Companies with adjacent power systems are showing an ever increasing tendency to interconnect their properties. Supplementing previously published information, the following four articles classify and discuss the various interconnection services available.**

INTERCONNECTION refers to the physical tying together of two or more independently owned or managed electric systems for the purpose of realizing financial benefits or improvement of service by the interchange of power and energy. The importance of linking power sources, transmission facilities, and load areas is fully recognized. Interconnection aids the electric utility industry in providing the customer with an electric supply adequate to his requirements in quantity, quality, and reliability.

In order to take full advantage of an interconnection, careful studies must be made, based upon a thorough understanding of the problems of each of the systems. The various factors involved first should be classified and defined so as to avoid confusion and error in comparing different schemes.

The subject of interconnection may be considered under the arbitrary divisions of (1) classification of service; (2) evaluation or economics; (3) contract; (4) design and construction; and (5) operation. The first two divisions, namely classification and evaluation, are considered by A. E. Bauhan in the first of the four articles immediately following. The second article, that by G. M. Keenan, discusses the development and operation of interconnected power systems, placing emphasis on the execution of a well formulated operating plan. The third article, by E. W. Dillard and W. R. Bell, enumerates the advantages as well as some of the disadvantages and difficulties in operating a particular interconnected system covering the more densely populated sections of New England. The last of the group, an article by H. S. Fitch, describes the plan of interconnection and operation of contiguous power systems independently serving a vast industrial region of Pennsylvania, Ohio, and West Virginia. In this case each system is under separate control, both financial and operating, with all the diverse standards and ideas of technical, commercial, and accounting nature.

## Interconnection Services Classified and Evaluated

By
A. E. BAUHAN
Member A.I.E.E.
Public Service Elec. & Gas Co., Newark, N. J.

DETERMINATION of the economic merits of an interconnection, that is, its evaluation, is greatly facilitated by an orderly and logical classification of the services which that interconnection will render. Recognition of the various classes of service is not only helpful but is quite essential in the preparation and application of the interconnection contract, as each class of service requires different provisions and rates of payment. Such classification is helpful in rationalizing design, as for instance in determining whether the services to be rendered by the interconnection warrant a double or only a single circuit.

The classification offered here is not intended to be an enumeration of benefits rendered by interconnection but rather a delineation of the types of transactions which take place over interconnections. It is an attempt at earmarking or labeling the various amounts of power or blocks of energy in the light of what they do—of what service they perform—as necessitated principally by evaluation and contractual expression. Seven main service divisions may be recognized: emergency service, load diversity, firm power, storage power, intra-company use, economy flow, and unintentional flow.

Emergency service is the assistance which one company renders to another in the event of breakdown of equipment, unusual load demands, or other abnormal conditions resulting in power requirements in excess of the capacity of the normal power sources of the company in difficulty. When emergency service makes possible a definite recognizable reduction in the amount of generating capacity it is sometimes referred to as reserve diversity.

---

Based upon "Interconnection Services, Their Classification and Evaluation" (No. 31-106) presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1931.

Load diversity refers to those transactions which result in a saving of generating capacity by reason of the non-coincidence of the times of the peak loads of the interconnected companies. For instance, if a system having a morning peak is interconnected with a system having its peak at 5:00 p.m. a saving in generating capacity results. If the diversity is found to be, say, 40,000 kw., each at the time of its peak could receive from the other 20,000 kw., thus realizing a saving of installed capacity of that amount. Three subdivisions of load diversity, daily, monthly, and yearly, are illustrated in Figs. 1, 2, and 3. The total diversity saving is equal to the daily diversity of the combined-peak day plus the monthly diversity of the combined-peak month plus the yearly diversity.

Firm power arises when one company, instead of installing necessary generating capacity in its own system, chooses to buy power from the other system. It involves a sale contract of either long or short term, with a firm obligation on the part of the seller to hold available capacity for the use of the buyer in lieu of installed capacity.

Storage power transactions involve the conversion of energy generated off-peak in one system into peak capacity in another system, through the medium of storage, usually the storage of hydraulic potential energy. There are two classes of storage power transactions; (1) pumped storage, by which relatively low-cost energy is used to pump water into a storage pond during off-peak hours; and (2) improved utilization of storage, in which generation during off-peak hours is substituted for energy which would otherwise be taken out of storage. In either case the stored energy is utilized at such a rate of discharge and at such a time as will create additional capacity values. Examples of storage power transactions are illustrated in Figs. 4, 5, and 6.

Intra-company use refers to interconnecting facilities used by one of the companies in place of other facilities which otherwise it would have had to provide for its own purposes. Interconnecting facilities which may thus be used include transmission lines and structures, substation equipment, tertiary windings in interconnection transformers which take the place of separate two-winding transformers, and rights-of-way. In some of these transactions energy for intra-company use is commingled with interconnection flows, and in such cases contractual arrangements are necessary to provide for their separation and to limit the intra-company use so that interconnection flow is not unduly hampered.

Economy flow occurs when energy used by one system and which could have been generated by that system is for the sake of economy actually generated by another.

Unintentional flow is included because it is desirable to consider deviations from the intended flow and inadvertent flows when none is intended.

## EVALUATION

Before decision can be reached as to whether or not a proposed interconnection should be installed, it is necessary to estimate and present its economies. The following is intended to indicate the general procedure and mode of attack to be used in evaluating a proposed interconnection.

*Generating Capacity Savings*—From the load data and operating characteristics of the systems it will be determined that certain capacity savings are to be realized by taking advantage of the various services which have been enumerated. For instance the availability of emergency service may make it possible to reduce the spare capacity from 20 per cent or 25 per cent to 15 per cent, or from 15 to 10 per cent; or, where without interconnection it had been thought necessary to have three spare generating units, with interconnection it may be decided that two units will suffice. If there is load diversity in the interconnected systems this results in a comparatively definite capacity saving. Similarly, the opportunity for storage power transactions yields a determinable capacity saving.

*Capital Cost Saving*—After the amount of capacity saved has been ascertained the resultant capital cost saving must be determined by applying appropriate

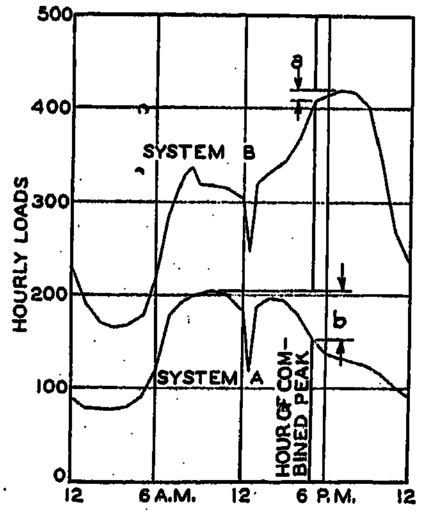

**Fig. 1. Daily load cycle**

Daily diversity = a + b

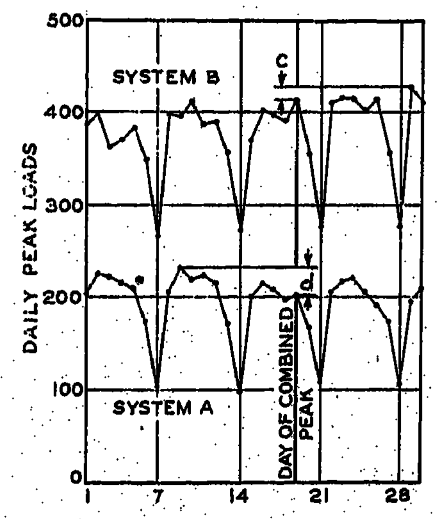

**Fig. 2. Monthly load cycle**

Month diversity = c + d

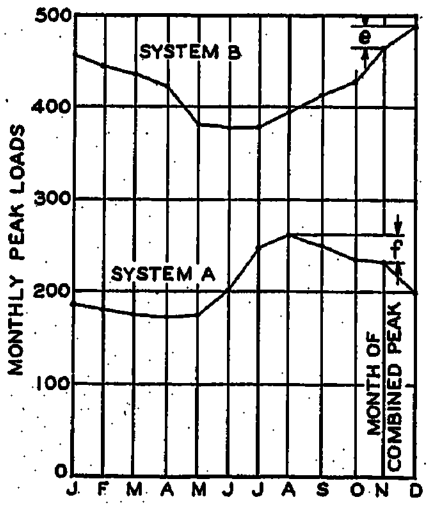

**Fig. 3. Yearly load cycle**

Yearly diversity = e + f

unit costs to the kilowatts of avoided capacity. If a more concrete study is being made, the particular year-by-year program of generating station investments "without interconnection" may be set up and compared with the "with interconnection" program. Any capital savings resulting from intra-company use of the interconnecting facilities or from firm-power transactions must also be taken into account. The total capital cost saving then is compared with the capital cost of the interconnection.

*Annual Fixed Charges*—Avoided investment naturally results in a reduction of generating station fixed charges. On the other hand, fixed charges are incurred on the interconnecting facilities. The term fixed charges ordinarily is meant to include the annual costs in money, insurance, taxes, retirement expense, and general expense; and in the case of facilities other than generating stations, it is sometimes convenient to include operation and maintenance expense. Usually they are determined and expressed as a percentage of capital cost.

The annual cost of money represents the compensation which must be given to capital to attract it to industry for the purposes under consideration. In the absence of abnormal conditions it is likely to be the prevailing allowable return on public utility property. Insurance, it should be remembered, includes not only premiums paid for all types of protection but also the cost of any self-insurance. Taxes can be determined only after careful consideration of the manner and the amount in which they are levied in each particular locality. Taxes levied on the gross receipts of the company ordinarily have no effect on interconnection economics. The necessity for including income taxes, with proper recognition of the effect of borrowed funds, must not be overlooked. Retirement expense should be determined on a sinking fund basis using the rate of interest earned on securities suitable for investment in trust funds. General expense includes administrative salaries, general office expenses, law expenses, relief and welfare work, etc. In some cases it may be considered that general expense will be unaffected by interconnection.

Naturally, no generally applicable fixed charge percentages can be cited. However, to indicate the order of the fixed charges it may be said that for steam-electric generating stations they frequently will be about 12 or 13 per cent, and for hydroelectric developments perhaps 9 per cent or 10 per cent. For steel tower transmission lines fixed charges are affected somewhat by the proportion of the investment in right-of-way, but they may be from 12 to 14 per cent with operation and maintenance expenses included. Substations, likewise including operation and maintenance expenses, will be somewhat higher; usually between 14 and 17 per cent.

*Annual Production Expense Savings*—After the saving in fixed charges has been determined it remains to evaluate the effect of interconnection on generating station production expense. This requires, first, determination of station load schedules with and without interconnection and, second, application of the individual station production expense formulas to the end that the changes in the fixed and variable elements of production expense be determined.

The output of each station and the character of its load for most economical conditions with and without interconnection may be obtained by resorting to integrated duration curves, or duration curves, for the loads of the individual systems on one hand and for the combined system on the other, on an annual, seasonal, or monthly basis, according to the degree of precision desired. Due allowance must be made for the outage of generating units for normal and abnormal mainte-

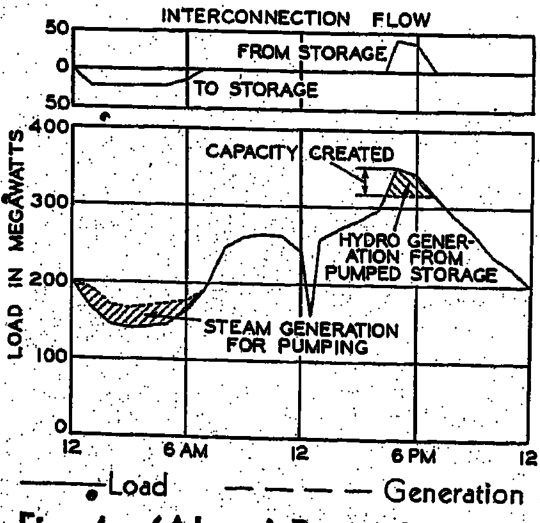

**Fig. 4. (Above) Pumped storage**

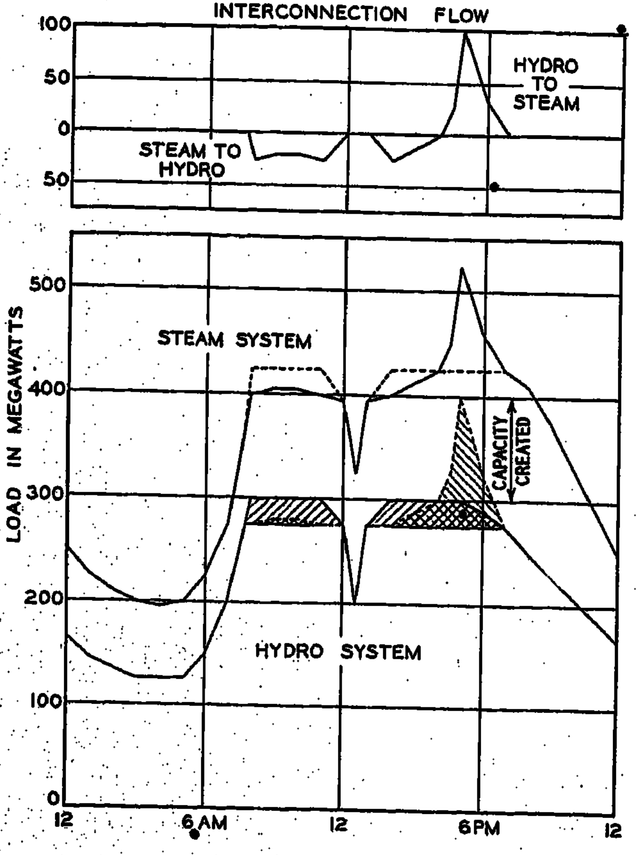

**Fig. 5. (Middle) Improved use of storage on systems having dissimilar peak characteristics**

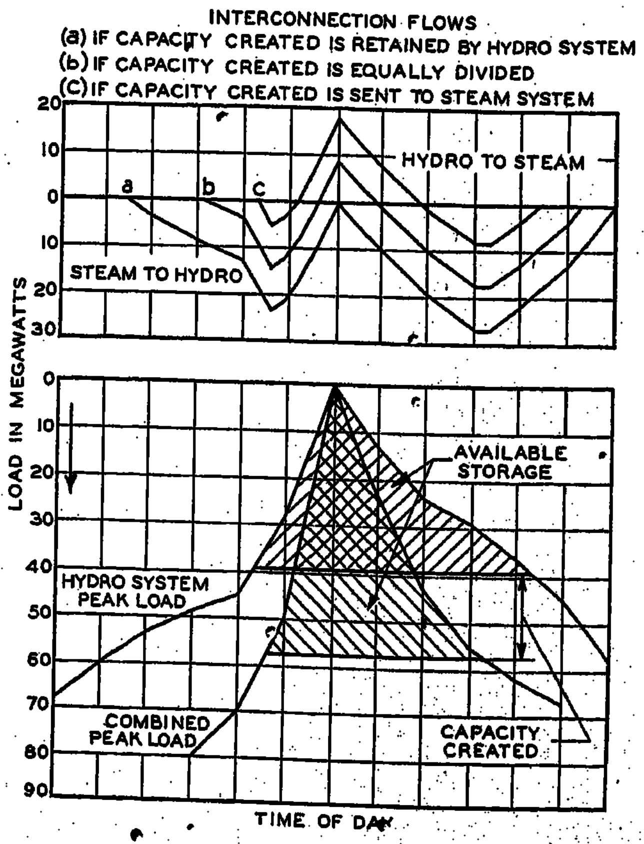

**Fig. 6. (Extreme right) Improved use of storage with similar system peak characteristics**

nance. It must be remembered that the interconnection transactions will be limited by transmission losses, the capacity of interstation and interconnection transmission, the necessities of service protection in local areas, minimum steaming conditions, and the minor imperfections of operation and of contracts.

Before the production expense savings due to interconnection can be determined it is necessary to know the behavior of production expense as a function of station output for each generating station in the interconnected systems. For interconnection studies the two-part annual production expense formula has been found sufficiently accurate and most suitable. Derivation and use of this formula have been discussed in "Presidential Address to Junior Engineering Society" by Dr. John Hopkinson in Transactions of Junior Engineering Society (British) 1892, and reprinted in *Rate Research*, v. 2, 1912, p. 23-38; and in "Discussion of the Elements Entering Into the Cost of Producing Power" by W. B. Skinkle in *Iron and Steel Engineer*, June 1928, p. 278. Such a two-part formula arises from the experience that within a limited range of annual capacity factors the production expense is made up of a fixed element independent of annual output and a variable element directly proportional to the number of kilowatt-hours generated in the period.

Obviously the avoidance of generating capacity installation accomplishes a reduction in the fixed element of production expense. Approximately, and frequently with sufficient accuracy in the case of a long-term study, the saving in fixed element expense is the number of kilowatts of avoided capacity resulting from the interconnection transactions multiplied by a figure (for large steam stations possibly between $3.00 and $5.00) representing the fixed element of production expense per kilowatt of avoided capacity. Its effect is similar to avoided fixed charges.

The change in variable element of production expense involves only the multiplication of the energy quantities determined for each generating station with and without interconnection, by the corresponding increment cost per kilowatt-hour from the two-part formula and obtaining the difference between the two plans of operation. Frequently the net effect of interconnection on this item is not a saving, but a decided loss. The explanation of course is that the interconnection forestalls installation of modern, highly efficient equipment, and increases the duty on older plants having higher variable costs.

*Net Savings*—Net savings resulting from the interconnection are obtained from the combination of net fixed charge savings and net production expense savings, which may well be presented by means of a tabulation showing the amount of these savings for each year studied.

No attempt has been made here to show how savings may be divided between the interconnecting parties, since this is a matter for agreement between them. Nevertheless, it is a factor which may affect some of the items of evaluation, and certainly requires careful recognition of the equities for each particular class of interconnection service in the agreements relating to the project.

# Interconnection Development and Operation

By
**G. M. KEENAN**
Fellow A.I.E.E.

Pa.-N. J. Interconnection, Hazleton, Pa.

SYNCHRONIZED electric supply systems function as a unit, all the component parts responding to variations in the load demand. Under the interest of single ownership this inherent unit characteristic naturally was recognized but through the screen of diverse interests of multiple ownerships in interconnection is not so clearly apparent. If the best economic results are to be obtained the development and operation of each part must be related to the development and operation of the whole unit.

How much coordination is required? Some believe that all the benefits of interconnection can be obtained only by developing and operating the system just as though it were all owned by one company. The trend in that direction is inevitable and the individual company's interests need not be submerged by such a procedure. Others believe all the practical benefits may be obtained with much less coordination; that continuing interconnection over greater and greater areas so complicates complete coordinating arrangements that they become economically unjustifiable, and that better results will be obtained by maintaining stronger company individuality. It generally is agreed, however, that there must be at least sufficient coordination to care for equities in established contracts and to avoid penalizing any of the participating companies.

## DEVELOPMENT OF INTERCONNECTIONS

Coordination in development of the interconnected system usually requires cooperative planning of generating capacity, interconnected transmission, border line service to customers, and system operating facilities. The intention is to provide the economically right

---

Based upon "Interconnection Development and Operation" (No. 31-119) presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1931.

electric supply system for the load areas served while so arranging the business relations between the ownerships as to share equitably the benefits between the customers and stockholders of the properties involved.

Generating capacity must be distributed economically among the various types of steam and hydroelectric stations strategically located in relation to the load requirements and properly correlated for the absorption of all available by-product power from irrigation, navigation, flood control, water supply and industrial development. There is no difference between this problem and that of a system under one ownership, except in the breadth of its scope and possibilities.

The interconnecting transmission system should be developed cooperatively to assure the economical utilization of the generating capacity and the reliable supply of electric service to load areas with sufficient operating flexibility in the system design to permit prompt resynchronizing when portions have been separated from the main system. The tendency is to increase transmission costs, and special effort is required to maintain the proper economic balance. Performance of interconnected loops is demanding more and more attention. Short-circuit current, stability, voltage regulation, and power flow in closed loops must be analyzed, and if necessary controlled by special equipment.

Service should be supplied border line customers in the most economical manner regardless of ownership, and the proper equities worked out between companies.

### Planning of Operation

Cooperative planning of system operating facilities is essential as a result of the unit characteristics of the interconnected system. The men directing the operation must be provided with adequate facilities to show what is going on, to determine how the performance should be properly correlated and readjusted, and to take the necessary action to accomplish the results required. The objective in the operation of electric supply systems is to produce most economically the most reliable service possible with the system provided; at the same time, maintenance must be accomplished efficiently. The coordination of all operating and maintenance personnel and operating equipment on the system to bring about this objective requires careful planning and execution.

Interconnected system operation differs from system operation under single ownership only in the method by which the objective is accomplished and in the necessity of properly caring for the equities resulting from differences in ownership. Some interconnected systems have gone to centralized control just as have all corresponding systems under one management. Planning with centralized control requires assembling yearly, monthly, and weekly load and maintenance forecasts for the various systems in the interconnection, and consolidating them into one interconnected system forecast. Operating schedules are prepared, based on these predictions and with a complete knowledge of characteristics and costs of all fuel generating stations, as well as quantity and limitations of available hydroelectric and by-product power.

On interconnected systems where centralized direction has not been established each company carries through its own planning and then checks with adjoining companies. Knowing the costs of the blocks of generation above and below that sufficient to carry its own load, each company determines with its neighbor where load and reserve can be placed for greatest economy.

### Execution of Operating Plan

An interconnected-system operator coordinates the performance of the individual companies in the execution of the operating plan where centralized direction is provided on the interconnection. The various company system operators do not report to the interconnected-system operator any more than a switchboard operator reports to a local system operator. Only such coordinating directions are given and received as are required to produce dependable, economical, unified operation; in neither case is there any need for loss of individual initiative or responsibility. The function of the interconnected-system operator in some cases is assigned by mutual consent of the companies involved to some one company system operator.

The interconnected-system operator keeps in touch with the demands made upon the system and the performance of the personnel and equipment in meeting those demands. His course is charted by the schedule of operation which has been prepared. He compares the demands which have developed with those predicted, and from his thorough knowledge of all elements of the system, adjusts the performance of equipment and personnel to compensate most economically and effectively for deviations of the actual from the scheduled demands.

Details of directing are so numerous that it is essential to develop a method of procedure which delegates as far down the line as possible, the detailed observation of indications and responsibilities for compensating adjustments. Direction is superposed only where coordination between the operating points is necessary. Every switchman, substation operator, and generating station operator usually is allowed to do all he can without coordinating direction from the local system operator of his area who, in turn, handles all he possibly can without coordinating direction from his company system operator. Methods of procedure and standard practise are established through written operating instructions reducing to a minimum the number of directions necessary for either emergency or normal operation. Complete and thorough training of all the operating personnel is essential to be sure that everyone can be counted upon to respond as promptly as possible, and thus harmonize action over large areas even though the individuals do not know just what is being done simultaneously by other individuals.

When such a system is well established with well trained personnel, lightning storms and similar emergencies are handled satisfactorily without any one person knowing all that is taking place; in fact often it becomes necessary to spend some little time on assembled records after the emergency is over in order to determine what actually happened and whether or not individual equipment and personnel have functioned properly.

Most existing interconnections have no centralized direction. The system operators of adjoining companies coördinate the performance of their companies and by such action, progressing through the interconnected group, produce unified operation. In exactly the same manner, many companies have handled their own operation between the switchboard operators at two or three generating stations before justifying system operators. The effectiveness of the de-centralized method is increased by occasional meetings of those directing operation of the individual companies where operating problems and practises may be reviewed and a mutual agreement reached on methods of procedure.

In a closed loop interconnection without phase shifting transformers or other such equipment, it is impossible to direct the power flow. Adjustments can be made only for the individual company's conditions by so regulating that company's generation as to produce the net power flow desired. As yet no satisfactory method of accounting for equities in interconnected loop operation between several companies has been developed.

Little attention is paid to the power flow on tie lines in a system under one ownership until there is danger of reaching some physical limitation on the circuit. Power flow on tie lines between different ownerships in interconnection, however, becomes one of the bases on which money is exchanged; therefore it becomes a part of execution of the operating plan to sort out, classify, and account for the different classes of power flowing. Unless care is exercised in establishing principles not only in operation but in the contracts, this work is likely to become excessively complicated.

As long as the properties are synchronized so-called incidental or uncontrollable power will flow across the interconnection even though no power flow is scheduled. It is necessary therefore to have an incidental rate which will encourage complete utilization of the instantaneous diversity without penalizing anyone.

An encouraging emergency rate is necessary which will induce everyone to rely upon the interconnection reserve but which will at the same time adequately compensate those properties producing the power in emergency. The rate used for a sustained emergency must compensate the property supplying the capacity and yet not penalize too severely the companies using the capacity, unless the necessity for this use has arisen from negligence in maintenance, poor planning, and development or wilful leaning to prevent investment in capacity.

In interconnection as in democratic government the total benefits to be shared are in proportion to the total participation; and the regulation imposed on the individual participant should be the minimum which is necessary to make the benefits proportionally available to all.

# Interconnection in the New England District

By
E. W. DILLARD
Member A.I.E.E.

W. R. BELL
Associate A.I.E.E.

Both of
New England Power Engg. &
Service Corp., Boston, Mass.

COMPREHENSIVE interconnection of power generating sources has developed in New England largely because of the high load density and the economical combination of hydroelectric and steam-electric sources which have existed in this territory. The first ties were made somewhat prior to 1917 and were used to obtain steam relay power for hydroelectric developments, and to provide a market for surplus energy generated by water power. More recent ties have been made to permit also the absorption of large quantities of surplus steam-electric power from high grade steam plants and to pool resources by the sale of firm capacity in order that economical construction schedules might be obtained.

## BENEFITS DERIVED

Interconnected companies not under a common financial control have not availed themselves of peak diversity to save capacity installation; each company has assumed responsibility for its own primary load. Although 5 per cent diversity amounting to say 50,000 kw. exists, this is utilized as a worthwhile safety factor, and the systems therefore are continually tied together even though kilowatthours are not exchanged. Between certain of the commonly owned groups, a larger di-

---

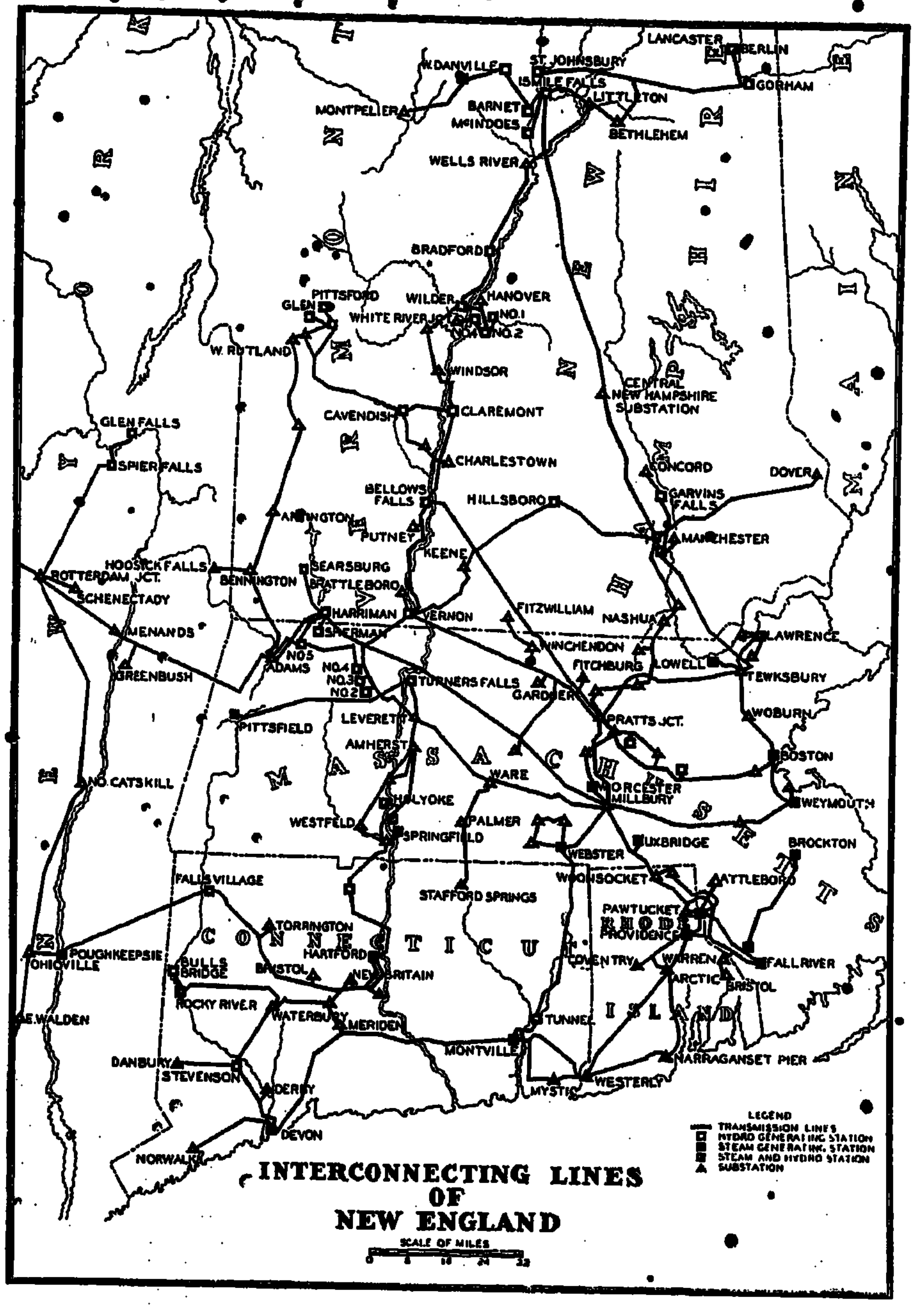

Fig. 7. New England interconnection

versity on the order of 7 per cent is utilized at a considerable saving. This diversity exists because of peaks occurring on different days of the week. On the interconnected system there is no large diversity due to differences in time.

No particular advantage is taken of reserve diversity. Individual companies usually carry spare capacity equal to that of the largest unit; interconnected systems usually carry about 10 per cent of their operating units as spare capacity. In general, it has been demonstrated that the loss of from 25,000 to 50,000 kw. on the system results in less than a 1/10-cycle drop in frequency.

Interconnected companies generally, as a matter of insurance, wish to keep tie lines closed as much as possible. There have been numerous instances in which tie lines have been valuable for emergency interchange upon the occurrence of apparatus failure, operating mistakes, and the like. Excellent relations exist between interconnected companies in such matters, and there have been but very few cases in which special charges were made for such services.

Low water is not classified as an emergency condition because all the major connected systems have water power sufficiently relayed with steam or purchased power. During various periods of fuel shortage, the New England power system, with the exception of the winter of 1917-1918, has been fortunate enough to obtain sufficient fuel for its own plants. It has taken advantage of interconnection by arranging to supply fuel to interconnected steam plants, in return receiving power at prearranged prices.

The use of interconnected lines for economy flow has shown large financial returns, and now, when surplus hydro power or economical steam is available, there is no operation of uneconomical plants excepting in some special cases where for special reasons there is a need of local generation. Almost all companies purchase power when it is to be had for less than local generating costs. The savings from major operations of this sort usually are split equally between the companies participating.

## CONTRACT RELATIONS

Usually no contracts are drawn for other than the purchase of firm capacity, and each company builds the portion of interconnecting lines in its own territory. The interconnected companies of comparable size have established a definite system whereby, based on cost differentials and demands, the generating costs of connected plants can be determined, and interchanges are worked out daily. Under these exchanges there is no guarantee of service but when economic conditions shift unexpectedly it is customary for each company to continue its schedule until, with mutual understanding, adjustments can be made. It is customary also for all companies to assist each other in emergencies.

Plans for interchange usually are made daily, in advance so that definite schedules can be arranged late in the afternoon for the following day. The New England power system dispatcher is in touch with the dispatchers of the adjacent systems and determines the quantities of power which can be furnished or absorbed. These compared with his own sources and costs readily determine the economical set-up for the day, and schedules are arranged.

## DISADVANTAGES AND DIFFICULTIES

One of the major difficulties that has arisen with interconnections lies in the inability to exchange an exact predetermined amount of power with a number of systems at the same time. Careful regulation of speed is of prime importance in this problem. Interchange has been controlled reasonably well by allowing one system to assume responsibility for speed control, each of the other systems taking care of the exchange over interconnections. Considerable work has been done in developing automatic frequency control apparatus which can hold speed much closer than the usual type of steam or hydraulic governor. This method of operation has a further advantage in the maintenance of more exact time for electric clocks.

## JOINT PLANNING OF CONSTRUCTION

The New England power system has had the good fortune to have many alternatives in planning additional sources of power. There have been possible water-power developments of various types as well as a variety of methods of extending steam generating facilities. The development at Fifteen Mile Falls was of such size that it could not be justified without various interconnections to assist in its absorption. Its character is such as to make it a desirable adjunct to any system depending entirely on steam, and this made it possible to sell a large block of power to the Edison Electric Illuminating Company of Boston.

The New England power system load has grown to such a size that the capacity and power requirements for growth should not be studied as a whole but should be divided into three major classes: (1) base load; (2) power or day load of 2,000 hrs. per year; (3) peak and spare capacity. These various classes of load grow about equally on a percentage basis, but the short-hour or peak type of load grows far faster on a quantitative basis. Additional requirements of base steam of the best grade grow slowly, and if this type of plant is increased too far in advance of requirements, it crowds into short-hour use expensive plants designed for better load factor. For the second class, the day load or 2,000-hr. power, it is apparent that plant capacity should be secured for a lesser first cost than for class one. A few hydro possibilities are peculiarly suited to this service. If the hydroelectric plant site affords sufficient storage, permits the power house to be close to the dam, and does not restrict its size, the increment first cost of unusual capacity may be favorable. These conditions existed at the Fifteen Mile Falls development. The water available at this plant, though sufficient to operate at full capacity but 2,000 hours per year, can be used when it is most valuable, and involves a negligible operating cost for additional capacity.

The third requirement of the systems is a capacity suitable for meeting annual peaks and carrying through the year and during the peak period day-to-day spare. The necessity of this sort of facility has been well illustrated by the development of the Rocky River pumping plant of the Connecticut Light & Power Company. The Fifteen Mile Falls plant also is well adapted to supply this type of power. While the older and rather uneconomical steam plants also are suited to this type of service, the cost of being ready to serve for peaks and spare is higher than that of suitable hydro plants. The Fifteen Mile Falls type of plant will confine their use for this purpose to a very small part of the year.

Interconnection has made possible therefore a large development of power of decidedly the type needed on the New England system and which also fitted well into the Edison system but not feasible of development without a very large or interconnected system. It has made the entire output of this development more immediately useful and has put off the construction of further base load steam capacity, which in turn will be desirable of construction in large blocks or more economical absorption later in the combined New England systems.

## FEATURES OF DESIGN

Automatic frequency control apparatus has been installed at three hydroelectric plants on the New England power system in order that it may be possible during a great many hours of the year to have at least one of the plants in position to handle the burden of speed control. Different operating periods for run-of-river plants and storage plants require that automatic frequency control apparatus be installed in both types of stations to insure automatic speed regulation being available practically at all times without departing materially from the normal economic schedule of operation. It has been found that a frequency deviation of not more than 1/20 of a cycle from normal approaches the best possible conditions for load interchange.

The increasing interconnection of transmission lines, together with the increased use and reliance upon electric power, is necessitating always greater reliability and freedom from disturbances. In New England, disturbances originating from lightning present the most formidable problem in transmission line operation. Where justified economically, transmission lines in this district are being built with unusually short spacing of supporting structures to secure a low average height above ground; and overhead ground wires usually are provided. Horizontal construction with single circuit towers and two overhead ground wires are being used generally on all major lines. The natural condition of high footing resistance that obtains throughout New England has been overcome partially by steel grillages for tower footings. Considerable betterment in the performance of transmission lines has been secured by increased insulation and proper line location. Sleet is another formidable foe, and attempt is being made to design major lines to operate through the worst sleet conditions with not more serious troubles than broken conductors. Vertically spaced line designs generally have been abandoned. Considerable use has been made of sleet thawing.

As the result of high speed oil circuit breakers and high speed relays now being installed a considerable improvement in operating conditions is expected. The Fifteen Mile Falls development was equipped with 220-kv. circuit breakers having an over-all relay and circuit breaker operating time of the order of eight cycles (0.13 sec.) and it is hoped to secure similar characteristics in breakers purchased in the future for the lower voltage developments. Tests on the 220-kv. breakers, some of which were taken under actual operating conditions, showed the removal of short circuits in quite a spectacular fashion, with only very small voltage disturbances and a remarkable lack of damage at the point of application of the short circuit. Considerable increase in synchronizing power during the short circuits also was secured.

Experience with this system indicates that the economical application of a high voltage interconnection necessitates such power factor correction as to insure the operation of the high voltage lines at practically unity power factor. Interconnected lines must operate also at a somewhat less drop in potential to avoid voltage variation when the point of feed is shifted on the system. Approximately 180,000 kva. of synchronous condenser capacity is in operation on the New England power system, and has proved justified on the basis of economy of transmission and voltage control. On the New England system there has been no occasion up to the present time that has necessitated the use of load ratio control for shifting load or balancing power between parallel circuits. No-load tap shifting devices have a widespread use on this system; their operation has been so successful that the New England companies were among the first to standardize upon external tap shifting devices for practically all important transformers.

# Pa.-Ohio-West Va. Interconnection

By
**H. S. FITCH**
Associate A.I.E.E.

West Penn Power Co., Pittsburgh, Pa.

TEN INDEPENDENT operating companies of western Pennsylvania, eastern Ohio, West Virginia, and Maryland operate normally in parallel to secure the manifold advantages of the interconnection of their facilities. Each of the systems has had its own romantic growth from the small local generating plant to the highly developed load area with its network of power lines furnished by modern power stations. It was proper then that these independent neighboring companies should cooperate to realize the benefits of interconnection. These benefits now are being secured, the common understanding of every day problems of parallel operations being secured through the working committee of operating men from each of the ten individual systems.

The territory served by the ten operating companies constituting this interconnected system has an approximate total area of 101,000 sq. miles, and a population of about 9,000,000 including 300 cities and towns of all classes. An estimate of the peak load of this group for 1930 occurring in December between 9 and 11 a.m. is 1,750,000 kw.; the annual load factor is about 70 per cent.

### CONTRACTUAL RELATIONS

Reliability of service, capital investment economy, operating economy, and the stabilization of frequency, voltage, or reactive kilovoltampere conditions on transmission systems, are all represented on the contractual relations of these interconnected companies. Neighboring companies first contacted on the frontiers of their respective systems for the mutual protection of those districts having only one source of power. Ever since 1916 capital investment economies have been secured on these systems by the use of short-time contracts for the purpose of dovetailing the steps in power station building programs. In this manner, the economic waste that goes with building generating stations too far in advance of the individual system load has been eliminated by staggering construction between independent companies.

An example of the combined financing of power stations exists in the Windsor power station owned jointly by the Ohio Power Company and the West Penn Power Company. This station built jointly in 1917 produced all the major benefits of the interconnection of generating facilities as well as many other operating and investment economies. Combined financing of transmission lines also has been secured between the Associated Gas and Electric Company and the West Penn Power Company by working out a program whereby each company constructed sections of high voltage transmission line serving its own system and then tying in with other sections owned jointly by these companies. Five years of perfect cooperation have been the result of this unique arrangement.

A strong transmission backbone now exists throughout the ten interconnected companies, and the whole system is a fine example of how planning and operation can be accomplished safely with a much lower percentage in spare generating capacity than is possible without such interconnection. The reserve capacities are so distributed that what any one system will be called upon to furnish represents in many cases only the overload capacities of the machines in usual operation. Another factor, the protection of service based upon mutual assistance when necessary, is commercially the most important of all the possibilities of interconnection. Several instances of emergency have proved the benefit of this form of protection.

### OPERATING BENEFITS

The study of the problem of reduction in spare generating capacity on this interconected transmission system has resolved itself into two phases; one, the

---

Based upon "The Pennsylvania-Ohio-West Virginia Interconnection" (No. 31-103) presented at the A.I.E.E. summer convention, Asheville, N.C., June 22-26, 1931.

utilization of the operating or spinning reserve capacity of the generating units, and the other, the coordination of the operation of the reserve capacity between these various companies so as to carry the required spinning reserve in the most economical manner. The resultant diversity by combining spinning reserve capacities makes possible a decrease in the total reserve capacity in service without the loss of reliability, and the proper proportioning of the spinning reserve capacity between the component parts of the system materially decreases the amount carried on any one system. On this interconnected system it is believed that the spinning reserve carried by any one company should be 10 per cent of the load carried by a steam station and 5 per cent of the load carried by a hydro station. When any one company generates more than 20 per cent of its load on any one steam unit, it should carry as its portion a spinning reserve equivalent to 50 per cent of the load on this unit. Each of the two metropolitan systems serving Cleveland and Pittsburgh with their adjacent territories carries its own reserve, equal to the largest unit on its system. These urban systems follow the practise of holding this reserve only in the overload and less efficient capacities of the generating equipment actually in operation.

Windsor station, being the central point of the interconnected system, acts under supervision of the working committee as a clearing house for all data on existing reserve capacity. Any changes in spinning reserve capacity desired by one of the companies are transmitted to the Windsor dispatcher. In no case is the spinning reserve deficient for more than two hours. If an accumulation of circumstances causes the required spinning reserve to be decreased by more than 25 per cent, the Windsor dispatcher at once has a check made of all possible reserve, and if the actual spinning reserve is not equal to at least 7½ per cent of the then total system peak, he requests that additional capacity be placed in service at the most convenient location as soon as possible. Through the proper use of this reserve generating capacity the interconnection has wrought such wonders that the public is often unaware that trouble has ever occurred.

The tying together of small communities within the same system commonly results in a large saving due to load diversity; however, it has been found that the

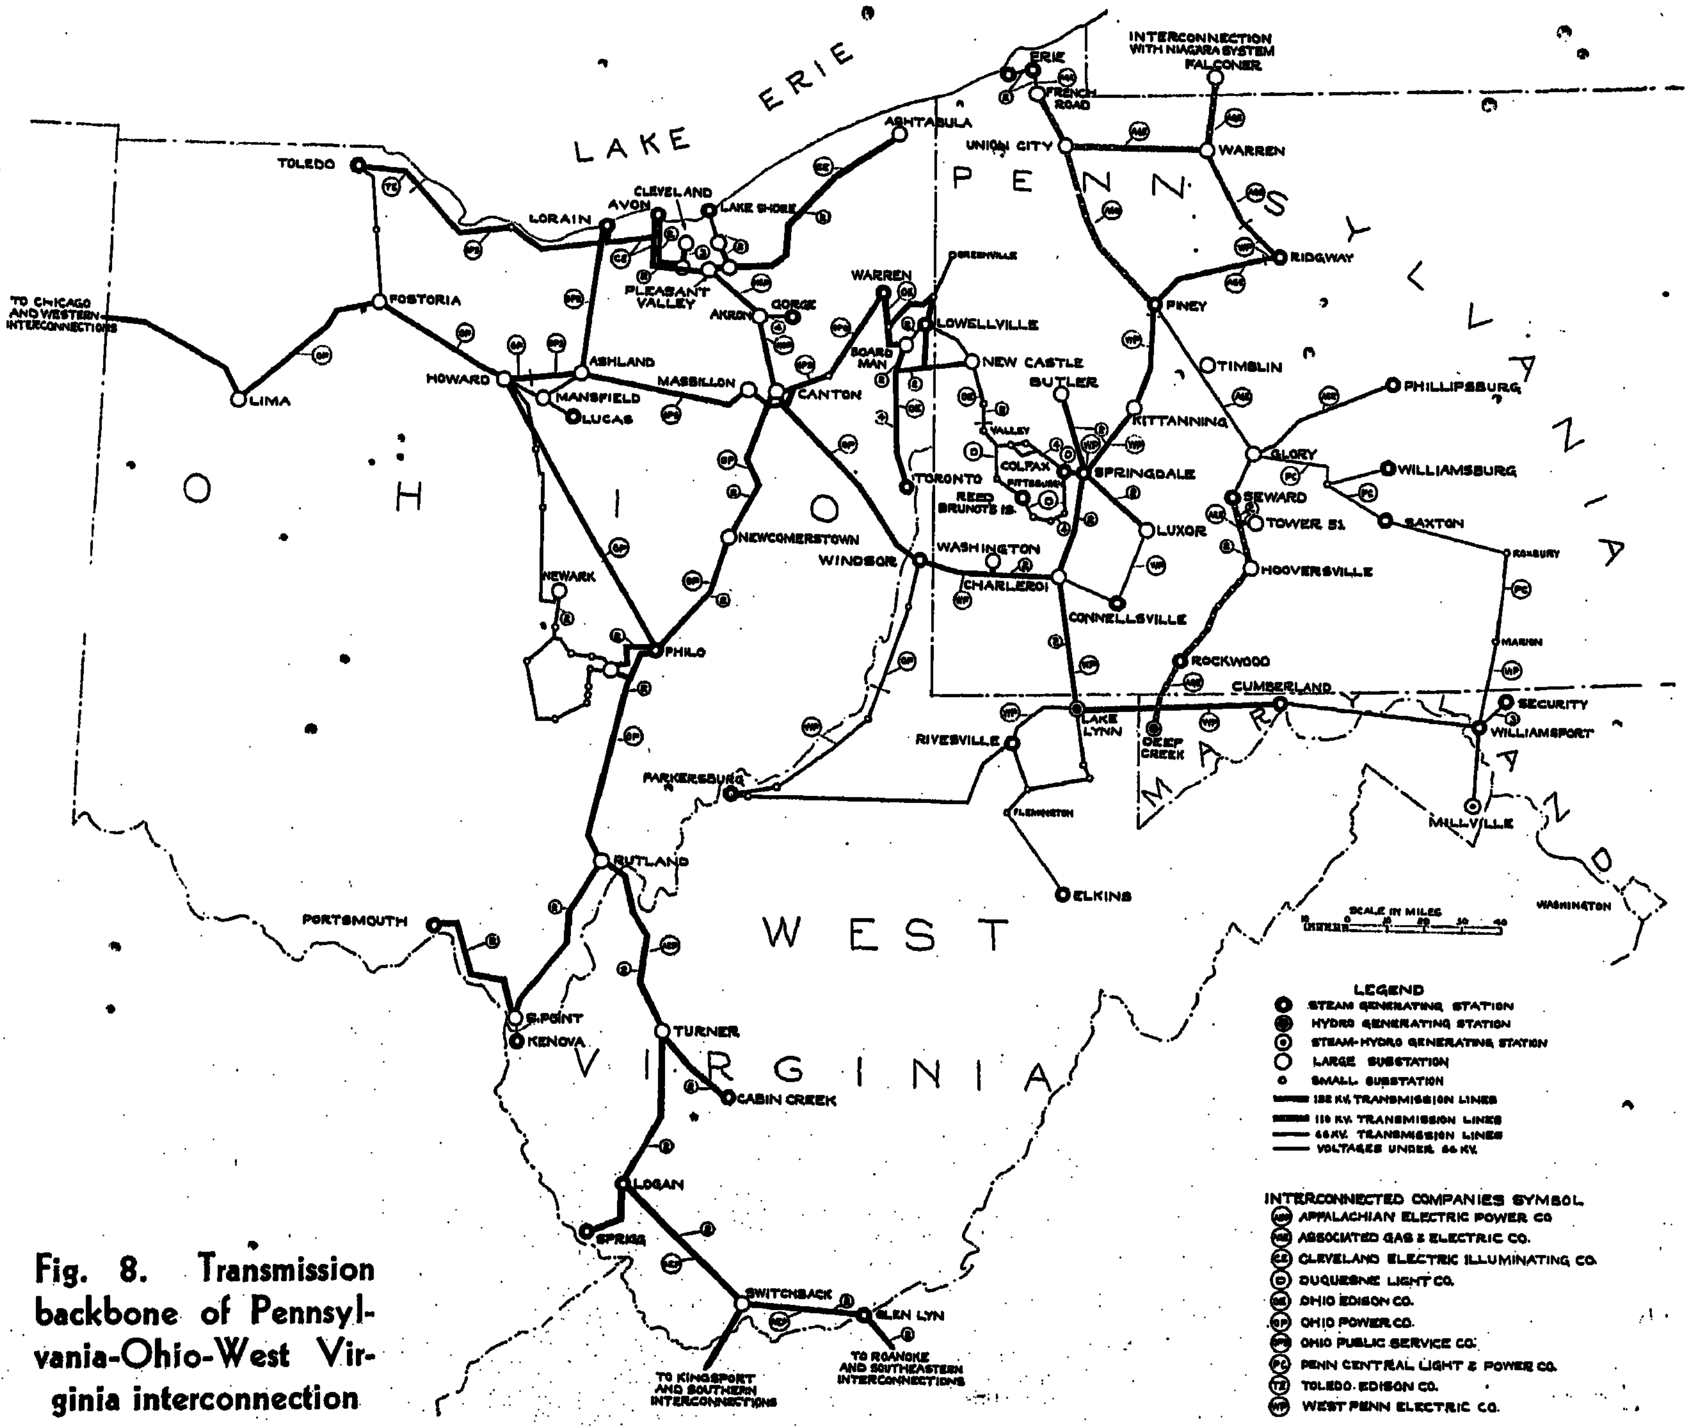

**Fig. 8. Transmission backbone of Pennsylvania-Ohio-West Virginia interconnection**

interconnection of large systems does not produce this same diversity saving. A typical case is that of the western part of the interconnected system on which, with a system peak of 490,000 kw., the diversity between the four individual systems was only 15,000 kw. or 3 per cent.

The expected diversity between industrial and lighting loads cannot always be secured, as there are times when the evening peak of the groups serving essentially industrial systems approaches within 8 per cent of the morning peak. Also, the low water conditions prevailing since November 1929 create an evening peak for the steam stations. The diversity in the industrial load itself has increased noticeably during the last two or three years, no doubt due to the use of off-peak power by many industries. The difference in time between sections of the interconnected system is scarcely noticeable in the group as a whole.

Fig. 9. View of switchboard room and load dispatcher's headquarters at Windsor station

## STABILITY

Installation of the 132-kv. transmission backbone and care in the selection of characteristics of equipment at the terminals, have caused instability to be no longer the serious problem that existed with earlier interconnections. As Windsor is the center of all interconnected operations, so is this station the center of the stability problem. The generators at Windsor are of the large air-gap type with a high short-circuit ratio, requiring a heavy no-load magnetization. Consequently with full excitation and no-load a low maximum voltage is indicated. These machines are not much affected by load changes and are inherently stable. The voltage regulators at Windsor are of the Tirrill type, one per exciter direct connected to its generator. From the standpoint of stability this arrangement of exciters is satisfactory, since steam units do not overspeed to any great extent. The voltage regulators operate in parallel through the usual compensating coils which force a correct sharing of the reactive kilovoltamperes. Automatic frequency control normally operates upon three units.

Throughout its history the Windsor station has stood like a rock against the many momentary surges transmitted to it from the east or the west. It has handled successfully many rapid load changes on the order of 50,000 to 90,000 kw. The problem of stability on each system is mainly staying in synchronism with Windsor.

East of the Windsor station a main transmission line extends 41 miles to Charleroi substation, from which a main transmission line extends south to the Lake Lynn hydroelectric station, and north to the Springdale steam-electric station. Most of the eastern parts of the interconnected system are tied in at these two last named stations. The synchronizing power of the lines between Windsor and Springdale, and between Windsor and Lake Lynn, is 500,000 kw., which is ample to hold these stations together. The generating units at Lake Lynn and Springdale have a low short-circuit ratio.

An unusual situation exists between two of the systems which are so tied together through autotransformers with dead-grounded neutral that either system may receive ground fault disturbances from the other. However, so far no difficulty has been encountered from these connections.

The most vulnerable point of this eastern system is near the Springdale station where there is a short-circuit capacity of 1,200,000 kva. Calculations indicate that a three-phase short-circuit fault must be isolated within 16 cycles or the units are likely to go out of step. A severe case of dynamic instability on the occurrence of a fault on both of the two 132-kv. lines near Springdale caused two generators to trip out on overspeed. Following this the excess voltage protective devices of the voltage regulators at Springdale were removed from service, and the subsequent occurrence of a more severe short circuit caused no generators to be tripped out of service.

In several instances the high power factor and low generator short-circuit ratios at Springdale have caused the operators to place a leading power factor upon a generator during load shifting, with the result that the generators fell out of step, without however interrupting service.

The interconnected systems to the west of Windsor station are somewhat more extensive and complex; certain of the lines form a 250-mile high voltage transmission ring involving five power companies with a total generator capacity of nearly 1,250,000 kw. Occasional operation with this ring closed on itself has demonstrated the inflexibility of interchange control, and therefore the loop is left open. Comparatively few cases of static instability has been reported on any of the interconnected systems.

The regulation of the flow of reactive power and the distribution among generating units is not a problem on this interconnected system. This is due largely to the high power factor maintained on lines and generating stations, made possible by the character of the load and the synchronous condenser capacity located at the transmission substations. On the systems of the West Penn Power Company and the Ohio Power Company alone there is synchronous condenser equipment totaling 172,500 kva. not including the generating units at hydroelectric stations which may be operating with low gate opening. The voltage of the generating units at the principal power stations is held practically flat, there being not more than a 3 per cent variation between light and heavy load. Load ratio control equipment is used to a limited extent to give control of the reactive current.

### FREQUENCY AND POWER FLOW CONTROL

Close regulation of the load among the interconnected systems of this group and among the individual power stations of each system has been a most difficult problem. It has been necessary for the working committee to hold many meetings to analyze these problems and determine a common basis for action. These meetings have been followed by continual educational work among the load dispatchers and switchboard operators until satisfactory operation has been accomplished.

Early in 1929 the working committee decided that Windsor station with six 30,000-kw. generators be assigned the task of holding a deviation from 60-cycle frequency of less than 1/20 cycle. As no automatic frequency control equipment had been installed, one operator on each shift was assigned to the duty of holding steady frequency by adjustment of the six governors. Operators in the other stations were instructed to disregard frequency entirely and concentrate on maintaining a close adjustment of tie-line load. The success of this new scheme of operation is indicated by the fact that whereas it had been the usual practise to adjust tie-line loads three or four times an hour, three or four times a morning, afternoon, or evening then sufficed.

In 1930 automatic frequency control equipment with an adjustment range of 0.25 cycles plus or minus was installed. Although arranged to control all six generators, it was found that with normal operation three or four generators were adequate to hold the system frequency to within 1/40 cycle of 60 cycles.

After a year's study of frequency regulation by Windsor station only, it was found that the only real difficulty of this scheme of regulation occurred at the periods of day when the load was shifting rapidly as at 7 a.m., the noon hour, and 6 p.m. Additional automatic frequency control equipment is now being experimented with at other stations. Preliminary tests would indicate that the objective has been achieved.

# Forecasting Population for Engineering Purposes

**Population forecasts, when carefully and intelligently made, serve a valuable purpose in helping to direct the employment of labor and capital to places or projects where they are most needed. Such forecasts cannot be based on formulas, but require careful weighing of many related factors.**

By
J. N. HOLSEN
Southwestern Bell Tel. Co., St. Louis, Mo.

ENGINEERS and persons responsible for the management of engineering projects have a common interest in problems of forecasting population growth and market demands. The soundness of engineering projects depends upon their capacity to fulfil a real demand; unsoundness or even failure may result from planning and designing engineering projects without regard to industrial and population trends. Similarly, city planning, housing and home building projects, and educational and social programs of various kinds ordinarily should be based upon the number of people to be served at some future date and their economic and social characteristics.

Within the Bell System the careful study of factors influencing the growth, distribution, and character of the population is regarded as essential to the intelligent planning of the telephone business. Engineers are provided with forecasts of the probable telephone service requirements at periods ranging from five to twenty-five years into the future; on the basis of these and other pertinent factors, the initial and ultimate size of buildings, switchboards, underground cables, and the pole lines and aerial cables are determined. In planning for the future, the central aim of the telephone company is to supply the right amount of facilities in the right place. Manifestly this cannot be done except when based upon dependable forecasts of population and its distribution.

Several mathematical formulas have been devised on the assumption that future population can be determined from past trends by the mere application of figures in the formula. It is believed, however, that such formulas place too much emphasis upon past

---

Based upon "Forecasting Population for Engineering Purposes" (No. 31-138) presented at the A.I.E.E. South West District meeting, Kansas City, Mo., October 22-24, 1931.

trends, ignoring the fact that new influences are always appearing and that old influences are frequently ceasing to be of importance.

Cities and regions grow not from mere wishing or boasting, but usually because of definite geographic and economic advantages which enable them to develop population supporting activities in competition with other localities. Forecasts are apt to miss the mark rather widely if the forecaster has only a local point of view. A national outlook eliminates the optimism based upon the pride of those born or residing in the particular locality for which the forecasts are being made, and the conclusions reached by a broad point of view undoubtedly are much more likely to be realized.

### POPULATION OF THE UNITED STATES AS A WHOLE

Because communities are competing with each other, population forecasts for states and for individual cities should be made with due regard to population trends of the country as a whole. Some of the facts and tendencies that have a definite bearing upon the population growth of the United States may be summarized briefly as follows.

The United States is almost certain to continue a restrictive immigration policy for many years to come. Until the last decade, immigration contributed heavily to our population growth. This is clearly evident from the 1930 census figures which showed that foreign-born whites and their children constituted 31.1 per cent of the country's total population. In the future, population increases must depend more and more upon the excess of births over deaths.

The birth rate in the United States has been declining gradually for several years, due to such factors as generally higher living standards, smaller living quarters, marriages in which both husband and wife are breadwinners, the tightening of immigration restrictions against the prolific races, and finally wider knowledge and utilization of birth control information. Although there have been reductions in infant mortality, the effect has not been sufficient to prevent a decline in the rate of natural increase. For example, in 1910 the birth rate was about 30 per 1,000 population and the death rate was 15, while at present the birth rate is very close to 19 and the death rate about 12. Thus, in twenty years the margin which represents natural increase in population has decreased from 15 per 1,000 to 7.

The number of people in continental United States in the last forty-year period together with increases in each ten-year period is indicated in Table I.

The gain during the 1920-1930 decade exceeds by more than one million the largest previous gain, that occurring in the period 1900-1910, and it is 3.3 million in excess of the growth realized in the decade just preceding, that is, from 1910 to 1920, when the net immigration was 25 per cent greater and the rate of natural increase some 10 per cent higher. A partial explanation of this seeming inconsistency is in the probable greater efficiency with which the 1930 count of inhabitants was made. Furthermore, the period of counting for the 1910-1920 decade was some six months shorter than that of the 1920-1930 decade. It seems evident that the natural rate of population growth has been steadily slowing down, and that the same general tendencies will prevail over the next twenty years.

### TREND FROM COUNTRY TO CITY

Now the slackening in the rate of population growth for the country as a whole naturally will be reflected in the population increase to be divided among urban and rural communities. Unless a community is relatively better situated than in the past, it cannot expect to maintain its past rate of growth. This is emphasized by the increasing mobility of the American people who always have been peculiarly ready to move in response to economic activity. The development of improved means of communication and transportation and the rapid spread of comparative information have accentuated this mobility. Thus the real advantages or disadvantages of communities are likely to play a more important role than heretofore in determining their relative capacities to attract or to hold a population.

Urban population has been increasing at a far higher rate than rural population. During the past decade the increase in the rural population was 2.4 millions as against 14.6 millions for the urban centers. Whereas the 1900 census reported only 40 per cent of the population as urban, the corresponding figure in 1930 was 56.2 per cent. This tendency is related intimately to fundamental economic changes, including the capacity of the farms to maintain a rapidly increasing urban population, and the transfer to the cities of many labors that formerly were a part of farm work. Contributing factors lie in the tendency of our export trade to shift from raw materials to manufactured commodities, the increasing per capita demand for these products in this country as a result of the rising standard of living (a tendency that is temporarily obscured by the present general business depression). Further contributing facts are in the additional opportunities for untrained workers in the cities brought about by both the decrease in foreign labor supply after the drastic restrictions on immigration went into effect and by the unusual growth in the service industries.

Further scrutiny of the census figures indicates that in general the larger cities in the country are growing more rapidly than the smaller cities. Between 1920 and 1930 the total growth of the ten largest cities in the United States, including their suburban territories, accounted for approximately 40 per cent of the total population increase of the country. The entire group of cities of over 10,000 population obtained 68 per cent of the country's total increase; and if the suburban areas of cities of over 50,000 population were included, the proportion would be raised to 86 per cent. Not only has urban population been increasing at a far higher rate than the rural population, but the tendency is one that probably will continue into the future.

### FORECASTING POPULATION OF A STATE

A series of economic surveys was made by the Southern Bell Telephone Company between 1924 and 1930 with a view to providing a more or less definite picture of economic conditions and trends in the five states in which it operates. The general plan of these studies involved an analysis and presentation of the following subjects:

1. Natural features, including a study of land form, soils, climates, vegetation, and water resources, with respect to their influence on activities.
2. The situation and outlook of each state's basic industries—agriculture, manufacturing, lumbering, and mining—in relation to population.
3. The comparative conditions and prospects in the various natural or economic-geographic regions of the particular state, the regional treatment being essential because of the dissimilarity of conditions prevailing over most states.
4. A detailed analysis of the situation and outlook of the principal cities.
5. The effect of the probable population changes upon the demand for telephone service.

Illustrative of the kind of questions for which answers were sought by the state economic surveys are these: How will the expansion (or perhaps contraction) of agriculture be distributed over the state? Will farmers have a greater or lesser purchasing power? What is the manufacturing outlook in the state? What kind of manufacturing activities may be expected to expand and what about their localization? Will the increase in the population-supporting activities be sufficient to cause the state to attract large numbers of persons from other states?

Personal inspection tours of each state were considered essential, following the collection and careful review of such information as was available. Contacts had been established with organizations and bureaus throughout the area, and during the inspection trips interviews were possible with persons in many lines of work. Of course all of the material and suggestions gathered in this manner could not be accepted at face value since local pride and enthusiasm were not always restrained.

### FORECASTING THE POPULATION OF A CITY

By the nature of things, no two cities present situations precisely alike; indeed, one of the most striking facts is their dissimilarity. However, in analyzing the past growth of a city and forecasting its future, there are usually five principal influences to be considered:

1. Size and character of its tributary trade territory
2. Its industrial expansion
3. Its attraction as a home center
4. Governmental activities
5. Institutional activities

**Table I—Continental United States**

| Year | Total population | Increase during previous decade |  |
|---|---|---|---|
|  |  | Number | Percent |
| 1890 (June 1) | 62,947,714 |  |  |
| 1900 (June 1) | 75,994,575 | 13,046,861 | 20.7 |
| 1910 (April 15) | 91,972,266 | 15,977,691 | 21.0 |
| 1920 (January 1) | 105,710,620 | 13,738,354 | 15.0 |
| 1930 (April 1) | 122,775,046 | 17,064,426 | 16.1 |

Study of the trade territory of a city is essential to an analysis of the population supported or likely to be supported by the wholesale, retail, and general office business of a city. This territory usually can be defined with the aid of an analysis of banking relationships, newspaper circulation, and the distribution of sales of representative wholesale establishments.

The trade territory of practically every city is changing, increasing or decreasing in extent and also undergoing changes in the character of the population. In respect to the latter, it should be remembered that the importance of a trade center depends not only upon the number of people in the tributary area but also upon their standard of living. In an analysis of the probable future changes in the trade territory of a city, consideration must be given to the trend in agriculture and industry, including such factors as improved highways, motor trucking, and changes in freight rates.

### INDUSTRIAL EXPANSION

It now appears that the growth of most of our cities during the next twenty years will be due primarily to their relative attractiveness for industrial expansion. For purposes of population analysis, it is helpful to classify industries. They may be grouped according to those which attract population, such as steel mills and automobile factories, and those which result largely from the presence of population, such as bakeries, laundries, and ice cream factories. Again, it is helpful to consider industries from the standpoint of whether they are conservative or exhaustive in nature; that is, whether their supplies are continuous or temporary. The lumber industry as it has been carried on in this country is a striking example of an exhaustive industry; in many places, industries (such as oil refining) based upon the presence of minerals are exhaustive.

If a city has diversified manufacturing plants, its growth is likely to be more uniform or stable than for a city where a single industry is dominant. It is well to note that different industries do not contribute to the population of a city in exact ratio to the number of employees. In a number of industries including the manufacturing of shoes and clothing a large proportion of the workers are girls and women, representing second and third members of a family. Further, one must consider the effects of labor-saving machinery. In the past virtually all industries have been able to increase their output by the application of labor-saving devices without a proportionate increase in the labor required, and it is certain that this tendency will continue.

There are many people who choose a place to live rather than a place to work. Among these are the independently wealthy, the retired, and the adventurers. These people seek living conditions to meet their desires, and adjust their occupations if necessary to what is attainable where they choose to live. The classes who seek places to live first and occupations afterwards are likely to increase in the future.

The national capital and many of the state capitals owe their growth primarily to the activities of the federal or state governments. In the past there has been a general tendency to enlarge the functions of governments, but for the immediate future it seems reasonable to expect an increasing pressure for more economical governmental administration expansion.

### EFFECTS OF INSTITUTIONS

Many cities in the country have military establishments, educational institutions, penitentiaries, etc., which add considerable numbers to the population. Sometimes institutions of this character are relatively so large and subject to such wide fluctuations in size that they tend to render past rates of growth of the city misleading, and to make forecasting of the future extremely difficult. In analyzing the population growth of such cities it has been found advisable to isolate the past population related to institutions and treat this influence separately in forecasting the future.

Many cities possess the advantages just described in more or less equal measure, yet their past and prospective rates of population growth vary widely. It is here that well-directed effort on the part of various civic bodies is important. The community which effectively advertises its natural advantages of location is likely to grow while a neighboring city equally well situated may stand still or even decline. Civic spirit is therefore a proper consideration in every population forecast. Through advertising activities a few of our cities have attracted a larger population than they can hold, and the slump which is bound to follow will perhaps permanently injure them. On the other hand some cities probably have retarded their growth by advertising which so glaringly exaggerated their attractiveness that their real advantages were overlooked.

In the telephone business, and in most other businesses where advance planning is required, it is important not only to know the probable growth of population, but also its character and distribution, and its division into family units. Future population growth is forecast upon the basis of certain definite factors already cited, including expansion of industry or commercial activities which support population. In estimating the amount of population that probably will be located in high grade, medium grade, and poor sections of the city, it is essential to know rather definitely the class of population supported by the various activities. Further, it is well to note that each part of a city is in competition with other sections of the city for the limited population growth of the whole community in much the same manner as cities compete with each other.

# Abstracts

## Of Papers to be Presented at the Milwaukee District Meeting

INTERPRETIVE abstracts of all papers to be presented at the A.I.E.E. Milwaukee District meeting (March 14-16, 1932) are presented herewith. Members vitally interested and wishing to obtain immediately pamphlet copies of any available papers are requested to use the order form appearing on p. 222 of this issue. In response to popular demand and within its space limitations ELECTRICAL ENGINEERING subsequently may publish certain of these papers, or technical articles based upon them.

### A General Method of Gaseous Tube Control

By
C. Stansbury[2]

METHODS devised for the purpose of controlling the mercury vapor rectifier tube by means of the hot cathode grid have been produced in much profusion for the past several years. However, certain novel control methods which it is felt are based upon fundamental ideas and should be of general engineering interest are presented in this paper.

It is shown that the inherent rectifying property of the cathode grid circuit lends itself to condenser-energy-storage methods of grid control which may take a number of forms. A typical set of control characteristics for a tube of the type described is shown, in connection with which it is pointed out that the response to grid voltage varies rather widely at different temperatures of the condensed mercury in the tube, except for anode voltages in the neighborhood of that at which the tube just starts with zero grid potential. This anode voltage is quite constant except at tube temperatures outside the normal working range, so that methods of control which take advantage of this fact give response comparable in accuracy to that of the high-vacuum tube. Various control circuits based on these principles are shown and described. (**A.I.E.E. Paper No. 32M6**)

## The Proximity Effect and Its Application to the Concentration of Heating Currents in Predetermined Strips

By
Edward Bennett[1]

IN ANY industrial operation such as welding, concentration of heating currents in particular parts of the metal presents obvious advantages. A method is described in this paper of concentrating these heating currents in predetermined strips of conducting plates, pipes, or other shapes. These are placed in close proximity to each other or to auxiliary conductors. They are so interconnected that heating currents concentrate largely in adjacent strips in close proximity to each other and in which the current flows in opposite directions. The shapes are connected with sources of alternating or oscillatory current of moderately high frequency. The method therefore consists in the use of an enhanced "proximity effect" to control the distribution of heating currents in bodies.

Mathematics and theory to assist in the solution of this problem are presented in the paper. Curves have been worked out to illustrate the control of the distribution of the heating current densities by means of this proximity effect. Unquestionably the control of the distribution of heating currents which is thus made possible opens up a new range of industrial heating effects. The method of selectively heating bodies by causing the heat energy to be generated in the body in strips of predetermined width and depth would seem to give a hitherto unattainable nicety of control of the distribution of temperatures in metallic bodies. (**A.I.E.E. Paper No. 32-54**)

## Electrical Instruments in the Gas Industry

By
E. X. Schmidt[2]

OPPOSITION to the use of electrically operated devices in the gas industry has disappeared because of the outstanding advantages of many forms of electrical control apparatus. Although the control of gas pressure generally is still mechanical, the flexibility and sensitiveness of electrical pressure controllers has made these devices a valuable asset in the distribution of gas. Thermal meters, calorimeters, and total heat meters are among those to which electrical devices are applied. The Thomas thermal meter makes possible the automatic measurement of gas flow at standard conditions independent of variations in the temperature, pressure, and saturation condition of the gas. The Thomas calorimeter, a device comprising an unusual combination of mechanical and electrical parts, provides a means for recording gas quality; while the Thomas total heat meter, an electrical combination of the above instruments, gives a direct measurement of the energy in the gas.

Heating values within 1 per cent, plus or minus, of a fixed value generally must be maintained. Therefore a calorific instrument designed for control purposes was developed. It is particularly useful for the automatic control of mixing two or more gases of unlike heating value to obtain a mixed gas of constant heating value.

The most recent development in the gas industry is the fully automatic gas plant for small communities. These plants are electrically operated and controlled, providing an uninterrupted supply of gas of constant heating value at constant pressure, a service which compares very favorably with that formerly enjoyed by large communities only. (**A.I.E.E. Paper No. 32M10**)

## Toll Switching Plan for Wisconsin

By
W. C. Lallier[3]

DEVELOPMENTS of telephone plant and technique have extended constantly the distance over which it is technically possible and commercially practicable to furnish toll telephone service. The result of this extension in the range of transmission has been to increase the number of possible commercial toll connections and to stimulate growth in toll service. In this paper, the toll switching plan for Wisconsin including some features of the transmission design requirements and the present and proposed toll cable network is outlined briefly. The relationship of the plan to that for handling countrywide toll connections also is touched upon.

It is found that the toll cable type of facilities gradually is supplementing or replacing the open wire type along many of the important routes of the system. It is expected that ultimately the use of open wire lines will be limited largely to the feeder and branch routes to cities and towns located some distance from the main toll cable route. A large majority of the principal open wire lines in Wisconsin now are arranged to have superimposed carrier systems operating upon them, and this application has been an important factor in providing for the increased toll traffic during the last few years. (**A.I.E.E. Paper No. 32-55**)

## Police Teletypewriter Communication

By
R. E. Pierce[4]

POLICE organizations throughout the country are rapidly adopting the latest development in record communication, namely, the teletypewriter. By this means alarms are typed at one point and simultaneously recorded in printed form at a large number of widely separated stations. The engineering for a modern police system involves not only the provision of the teletypewriter machine, but large networks of telegraph circuits with the associated switchboards, telegraph repeaters, power plants, and testing equipment which also must be designed, manufactured, and installed.

In adapting the teletypewriter to police work, some interesting problems have arisen. Usually service is of an intermittent nature and special arrangements are provided at the sending location for starting and stopping the distant teletypewriter. Also specially designed control arrangements are provided to allow an operator at general police headquarters to take control of an entire state network, including all groups of stations which normally would operate individually. In other cases an acknowledgment circuit is provided for advising the sending operator when a message has been received at a particular station. In certain types of offices where a number of stations is on one circuit, selective calling devices allow any one station to select any other station or group of stations on the circuit. Various types of leased networks are designed to fit particular needs of police organizations. (**A.I.E.E. Paper No. 32M8**)

## Weather Resistant Insulation for Line Wires

By
C. F. Harding[5]
L. L. Carter[5]
J. W. Olson[5]

GREAT ADVANCES have been made in the art of producing insulation for higher voltage cables, but it is only within the last two years that any unified and organized attempt has been made to improve the weathering and insulation qualities of the covering of weatherproof line wire. The relatively high cost and poor operating performance of weatherproof coverings on overhead lines of 4,000 volts and less, indicated the necessity for taking steps to improve the weatherproof covering or to discontinue its use entirely.

Complete testing equipment for determining the comparative life of different weatherproof wire covering was purchased or constructed for the laboratories at Purdue University. This very complete equipment has enabled a large number of conclusions to be drawn, the most important of which may be summarized briefly as follows:

1. The present triple-braid weatherproof wire covering may be improved materially by the use as saturants of higher fusing point blown asphalts, free of waxes and low boiling fluxes. Such a saturant will provide a covering of uniformly long life.

2. That the higher saturating temperatures required to apply such saturants may be used without damage to the cotton yarns or excessive annealing of the copper conductors, has been proved.

3. Specifications for weatherproof coverings soon will be written as a result of this work, the terms of which will guarantee weatherproof wire of long life.

4. Future work will provide a covering of lighter weight and smaller size, but of higher insulating value and longer life than does the present construction. (**A.I.E.E. Paper No. 32-56**)

## Development of the Waukegan Station of the Public Service Company of Northern Illinois

By
J. L. Hecht[6]

REASONS for the choice of site, general plan, and development of the Waukegan station are outlined briefly in this paper, further details being given in a companion paper by E. C. Williams. This station, located approximately 40 miles north of Chicago and on the west shore of Lake Michigan, has an installed capacity of 290,000 kw. It performs the dual function of supplying energy to a metropolitan system and a surrounding transmission system.

Following a careful study, the Waukegan site was acquired by the company in 1917, and subsequent developments have proved the desirability of this location. The first development period for the station was between 1922 and 1925, and consisted of a 25,000-kw. unit and a 35,000-kw. unit, both operated at 350-lb. pressure, with a total temperature of 675 deg. fahr. with no reheat.

During the second development period, between 1927 and 1930, a 50,000-kw. unit and a 65,000-kw. unit were added, the operating steam pressure being raised to 600 lb., with a total temperature of 725 deg. fahr. In the third period, just begun, a 115,000-kw. unit was placed in service September 1, 1931. At this time radical changes in switching arrangements were made. Considerable increase in the size of the station is anticipated for the future. (**A.I.E.E. Paper No. 32M9**)

## Electrical Design Features of Waukegan Station

By
E. C. Williams[6]

DEVELOPMENT of the Waukegan station through the three periods outlined in the companion paper by J. L. Hecht is described in the present paper. Details of the changes and the reasons for them are given.

The tendency toward metalclad switchgear in the development of this station is especially striking, the first 132,000-kv. switchgear of this type ever used having been placed in service as part of the installation for generating unit 5. This generator and its transformer operate as a unit without connection to the low voltage bus.

A number of interlocks on the switching and instrument transformer equipment is provided to prevent operating errors and to protect personnel. Also in designing the control and protective system for the automatic combustion-control equipment used with pulverized coal, unusual care was necessary to insure successful operation. Excitation equipment for the generators was designed to give economical and reliable operation. The paper outlines carefully the changes in practise, the novel applications of standard a-c. motors, the trend toward equipment providing greater safety for the operating personnel, better investment economics, and greater facilities of installation that have occurred at Waukegan station over a period of ten years. (**A.I.E.E. Paper No. 32-57**)

## 115,000-Kw. Turbo-Alternator

By
R. B. Williamson[7]

DUE TO the increasing use of large single-shaft steam turbine units, it has been necessary to design very large generators operating at 1,800 r.p.m. The present paper describes a 115,000-kw. unit recently placed in operation. The generator is wound for 18,000 volts and the whole output of the machine, with the exception of a small part used for the operation of auxiliaries, is stepped up to 132 kv. All switching is done on the high voltage side of the transformers. Therefore it was possible to design the generator for a voltage that would permit a simple two-conductor per slot winding.

Because of the great axial length of the machine, ventilation required careful study, and a new scheme of rotor ventilation was developed to secure uniform cooling throughout the length of the long rotor body. The stator ventilation is of the inward-outward parallel-flow type with fourteen parallel paths in each half of the stator.

Air circulation is provided by four single-inlet motor-driven blowers mounted under the generator. A fin type radiator cooler is mounted under the generator yoke and condensate is circulated through the cooler. Excitation is furnished from a 350-kw. 250-volt coupled, shunt-wound exciter, and a 7½-kw. overhung pilot exciter is used for the field of the main exciter. **(A.I.E.E. Paper No. 32-58)**

## The Mercury Arc Rectifier Applied to A-C. Railway Electrification

By

O. K. Marti[7]

THE BASIC principle of grid control used in connection with large mercury arc power rectifiers is reviewed briefly in order to explain a new application of rectifiers which was made possible by these improvements. This application is described, and it is shown how by its use a single-phase motor for a-c. railway electrification service with series-motor characteristics and for use on any commercial frequency can be designed. With the grid-controlled rectifier it was found possible to eliminate the commutator of the motor and practically all the expensive controlling, switching, and reversing equipment commonly used on a-c. locomotives. The data and layout of a 1,000-hp., 50-cycle, 15,000-volt, single-phase locomotive are given.

The experiments carried out on a locomotive with this type of motor have demonstrated the practicability of the scheme. Besides the advantages from the point of view of locomotive operation, this scheme makes it possible to use a power supply of any available frequency, whereas at the present time frequencies of 25 cycles or less generally are required. While it is too early to predict to what this development may lead, the already apparent marked advantages of a locomotive equipped with this type of motor, may revolutionize the practise of railway electrification.

## Mercury Arc Rectifier versus Rotary Converter Automatic Railway Substations

By

O. M. Ward[8]

EXPERIENCE in the operation of unattended, automatic, mercury arc rectifiers and rotary converter substations supplying 600-volt d-c. energy to overhead trolleys in interurban territory is discussed in this paper. Operating records covering a three-year period from November 1, 1928, through October 31, 1931 are presented for three mercury arc rectifiers, and two rotary converters of comparable size and operating under similar conditions.

As these rectifier stations were among the earliest installations with full automatic control in unattended substations, while full automatic rotary converter substations have been in service many years, it is manifestly unfair to compare these two types of stations for the first year or two of operation. Decided improvements have been made in rectifiers, and the 1931 record therefore may be assumed to be more indicative of normal performance. On this basis the records show that under conditions of operation existing in the Milwaukee interurban territory, the following conclusions may be drawn.

1. There is practically no difference in operation and maintenance costs of the two types of converting equipment, taking into consideration the higher efficiency of rectifiers.

2. Service availability of rotary converters is slightly higher than service availability of rectifiers when the converting equipment is unattended and equipped with automatic control.

3. Rectifiers have not been responsible for complaints from telephone companies or radio users.

4. Control system failures in whole or part are vastly more serious in automatic than in manually controlled stations.

5. More attention should be given to auxiliary relays, operating coils, protective equipments, etc., used in automatic control systems, to insure against faults in them. **(A.I.E.E. Paper No. 32M7)**

## The 60-Cycle Primary Transmission System of the Milwaukee Electric Railway and Light Company

By

C. D. Brown[8]

E. W. Hatz[8]

THE PRIMARY transmission system described in detail in this paper operates at 132 kv. and 66 kv. to transmit bulk energy from generating stations to step-down substations, and to interconnect the system of the Milwaukee Electric Railway and Light Company with hydroelectric plants in the northern peninsula of Michigan. The system is divided into power areas which are served directly from a generating station or from a step-down substation located near the load center of the area. Energy is distributed from these points over secondary transmission lines.

Tower lines are constructed where feasible on existing right-of-way of the electric railway system. High voltage lines are brought into the congested portion of the city over private right-of-way. Four types of tower line construction have been developed, three of which are used in special cases where lines are constructed on a railway right-of-way not sufficiently wide enough to permit the use of standard square base towers. This construction permits the conductors to be carried over the operating tracks of the railway system. The particular type of tower to be used is a question of economics determined by the cost of real estate at that particular location. The system is so planned that it is capable of indefinite expansion without major changes in existing equipment. **(A.I.E.E. Paper No. 32M3)**

## Insulator Sparkover

By

W. L. Lloyd, Jr.[9]

SPARKOVER strength of the various parts used for the insulation of modern high voltage transmission systems has been subjected to a detailed study, the results of which are presented in this paper. Line and station insulation, and bushings used on the station equipment, were subjected to tests to determine their sparkover strength under a wide variety of conditions.

Data are presented for both 60-cycle sparkover and lightning sparkover voltages, and all values have been corrected to an air density of unity. Considerable attention has been devoted to the effect of humidity and a number of interesting results have been obtained. These are shown in a group of tables and curves presented in the paper. Considerable data also are presented on the effect which smoke, steam, dew, fog, rain, and surface dirt and moisture have on the sparkover voltages of insulators. (A.I.E.E. Paper No. 32-59)

# An Improved Type of Limiting Gap for Protecting Station Apparatus

By A. O. Austin[10]

A COMPARISON of the impulse flashover characteristics of various forms of protecting gaps and of station insulation shows these characteristics to vary widely for different degrees of overpotentials. In the usual type of protecting gaps, little or no provision has been made for adjustment in order to have the arcing characteristics of the gap conform to the insulation for the range of transients encountered in practise.

A new form of protecting gap, the polarity and time lag characteristics of which can be adjusted over a wide range has been developed, and in this article is compared to the usual form of protecting gaps. The advantages of this improved type of gap in providing protection for a wide range of transients, and at the same time reducing unnecessary discharges of the gap to a minimum, are shown by tests wherein the effect of time lag is quite evident. The advantage of equipping the protecting gap with a fuse or other device is more apparent where a lightning arrester is not present to take most of the discharges.

The advisability of using a limiting gap to protect station apparatus from flashover under very severe overpotentials, in combination with a lightning arrester to relieve equipment of the majority of transients of lower magnitude, is suggested as a means of providing increased protection, at the same time reducing interruptions to a minimum. The use of the control type of protecting gap is proposed as a means of more easily coordinating station insulation on new as well as existing installations. (A.I.E.E. Paper No. 32-60)

# Design and Ecomomic Selection of Suspension Insulator Assemblies

By J. J. Torok[11]
C. G. Archibald[12]

A SUMMARY of data from extensive impulse and 60-cycle laboratory flashover tests upon suspension insulator strings relative to unit shell diameter and unit spacing is given in this paper. The insulating qualities and the economic advantages of the various sizes of units are discussed with due regard to the most recent lightning protection theories. Consideration is given to insulation for high voltage transmission lines of both the steel tower and wood pole types.

Based on this study, the following conclusions may be drawn:

1. The major factor of steel tower transmission line design is the shielding of the power conductors with properly located ground wires and maintaining the tower footing resistance as low as possible.

2. For towers of low footing resistance, on the order of 20 ohms, the wave is of short duration so that the minimum flashover voltage of the attached insulation corresponds to its breakdown voltage at 2 microsec. with a flat-topped wave.

3. In applying insulation to well protected high voltage lines, suspension insulators should be judged by their impulse flashover characteristics at 2 microsec.

4. The choice of insulation for lines not protected, or inadequately protected, by ground wires is based upon impulse flashover values at long time lags of the order of 10 to 50 microsec.

5. Impulse flashover space effectiveness of suspension insulators improves with increase in unit shell diameter at moderate spacings.

6. Impulse flashover space effectiveness for all unit diameters falls off with increase in unit spacing.

7. Flashover space effectiveness decreases with increase in string length.

8. The cost for a given impulse flashover voltage generally is lower for larger diameter units and higher for larger unit spacings.

9. Available service data and laboratory tests show that the 12-in. unit is as serviceable as a 10-in. unit. (A.I.E.E. Paper No. 32-61)

# Normal Frequency Arcover Values of Insulators as Affected by Size and Humidity

By H. A. Frey[13]
K. A. Hawley[13]

DATA covering the electrical characteristics of comparable insulators, as received from different sources, are frequently conflicting and a study has been made therefore to establish rules whereby such characteristics can be estimated with a reasonable degree of certainty from the dimensions of the insulators. A long series of carefully made tests are summarized in the accompanying table.

**Kilovolt Flashover Values Per Inches Arc Length**

| Insulator Type | Dry Value | Wet Value |
|---|---|---|
| Suspension<br>0 to 100 inches | | |
| Standard cemented | 10.5 to 9 | 7 to 6.8 |
| High strength cemented | 10.5 to 9 | 7 to 6.3 |
| Hewlett flat disk | 10.5 to 9 | 7.5 |
| Hewlett fish tail | 10.5 to 9 | 6.5 |
| Pin types | | |
| Small | 14 | 7 |
| Multipart | 14 to 11.4 | 8.9 |
| Apparatus insulators<br>(Dry 0 to 110 inches) | 11 to 7.3 | 8 to 5.7<br>(Erratic) |
| Equipment bushings | | |
| Solid type | 13.6 to 6.75 | 8.3 |
| (With bare conductor) | 12.4 to 6.1 | 8.3 |

Where two figures are given, the first applies to small insulators and the second to the larger insulators. In addition the ratio of wet flashover values in kilovolts to the wet striking distance in inches was found to be from 14 to 10.6 for high strength cemented suspension insulators, erratic for multipart insulators, and 13 to 10.4 for apparatus insulators. It was found that for dry arcovers the humidity correction per 0.1 in. mercury water vapor pressure was 2 per cent for standard cemented suspension insulators, apparatus insulators, and solid type equipment bushings; and 3 per cent for small, multipart, and pin type insulators. (A.I.E.E. Paper No. 32-62)

## Of Institute and Related Activities

# Winter Convention Success Due Largely to Committee Efforts

THE INSTITUTE'S winter conventon held in New York, N. Y., January 25-29, 1932, brought forth an official registration of 1,429 persons. This attendance was highly gratifying and definitely refuted the occasional predictions that attendance would be small. Of even more importance perhaps is the fact that interest exhibited in the technical sessions and other features of the convention was in line with the attendance. All in all the convention may be said to have been very successful.

### Opening of the Convention

The convention was officially opened at 2 p.m. January 25. Following introductory remarks by E. B. Meyer, chairman of the winter convention general committee, and W. H. Harrison, chairman of the technical program committee, the opening address was given by Dr. C. E. Skinner, president of the Institute. In his talk, presented elsewhere in this issue, Doctor Skinner outlined some of the activities and accomplishments of the Institute, and interestingly discussed the engineer as a citizen. At the conclusion of this speech, honorary membership in the Institute was conferred upon Dr. Frank J. Sprague, past-president of the Institute, and a pioneer in the development of electric traction. Doctor Skinner then stated that he had just received a letter from Sir Robert Hadfield, London, England, announcing a gift to the Institute of a bronze plaque commemorating the Faraday centennial. The meeting then was turned over to Mr. Harrison who formally opened the series of fourteen technical sessions. As abstracts of, or articles based upon, all 64 papers presented at these sessions already have been published (see Electrical Engineering for January 1932, p. 39-49, and for February 1932, p. 130-2), they will not be reviewed here. However, summaries of the discussions following presentation of some of these papers will be given in subsequent issues of Electrical Engineering.

One of the most impressive of the several interesting non-technical features of the convention was the joint medal presentation which took place on the evening of January 27. On this occasion the Edison Medal was presented to Dr. E. W. Rice, Jr., and the John Fritz Medal to Dr. M. I. Pupin. Many leaders in the engineering profession including several former Edison and John Fritz medalists were seated on the platform. These presentations, as well as the conferring of honorary membership upon Doctor Sprague, are reported elsewhere in this issue.

The success of the convention's annual buffet supper and smoker was repeated this year, on the evening of January 26, with an attendance of about 900. The committee responsible for this lively affair consisted of G. W. E. Draper, *chairman*, E. S. Banghart, W. G. Freeman, J. E. Goodale, R. A. McClenehan, L. K. Murphy, C. F. O'Neill, C. H. Sanderson, H. R. Searing, H. O. Siegmund, Morton Sultzer, and H. G. Wood. Following the buffet supper, an elaborate entertainment in the auditorium was provided by a capable master of ceremonies assisted by an excellent group of artists.

### Annual Dinner-Dance

The annual dinner-dance was held in the Grand Ballroom of the Hotel Astor on January 28, and proved to be well attended. This event was preceded by a reception in honor of Doctor Skinner. The receiving line, in addition to Doctor Skinner, included the three honorary members present, Dr. Ambrose Swasey, Dr. Chas. S. Scott, and Dr. Frank J. Sprague; E. B. Meyer, general convention chairman, and H. P. Charlesworth, vice-president of the Institute for the New York District. Responsible for the success of this occasion was the dinner-dance committee composed of E. J. Johnson, *chairman*, C. R. Beardsley, N. M. Garland, W. S. Hill, H. L. Huber, R. H. Hughes, J. F. Kelly, F. A. Muschenheim, R. F. Penman, C. S. Purnell, H. R. Searing, and D. M. Simmons.

Entertainment for the women was arranged by the ladies' committee with Mrs. E. B. Meyer as chairman, assisted by Mrs. O. H. Caldwell, Mrs. H. P. Charlesworth, Mrs. H. C. Dean, Mrs. W. H. Harrison, Mrs. F. L. Hutchinson, Mrs. C. R. Jones, Mrs. G. L. Knight, Mrs. R. L. McLellan, Mrs. W. R. Smith, Mrs. C. E. Stephens, and Mrs. R. H. Tapscott. Activities included the popular and well attended luncheon and bridge, many independent theater parties organized through committee assistance, and excursion trips particularly suited to the interests of the women. In arranging trips for both men and women, some noteworthy successes were scored by the inspection trips committee composed of W. R. Smith, *chairman*, I. S. Coggeshall, G. F. Fowler, Henry Kurz, H. C. Otten, R. D. Parker, V. A. Shields, H. P. Sleeper, and R. L. Webb. The most popular trip was that to the U.S. Naval air station at Lakehurst, N. J., where the U.S.S. "Akron" was inspected. The registered attendance for this trip was 379 persons. The next most popular visit was that to the studio of the Jenkins Television Corporation, attended by 141 persons, while the Empire State Building drew the third largest number with 67. A scenic trip up the Hudson River also was available, and in addition to specified trips to local points of engineering interest, opportunity was afforded the members and guests to select from a comprehensive list of plants which might be of particular interest to them. The registration for all inspection trips totaled 893.

Too much credit for the success of the entire convention cannot be given to the general convention committee and to the convention executive committee. The first of these, with E. B. Meyer as chairman, included O. H. Caldwell, H. P. Charlesworth, H. C. Dean, W. H. Harrison, C. R. Jones, G. L. Knight, C. E. Stephens, and R. H. Tapscott; while the executive committee consisted of C. E. Stephens, *chairman*, C. R. Jones, *vice-chairman*, G. W. E. Draper, E. J. Johnson, Mrs. E. B. Meyer, and W. R. Smith.

The officially registered attendance at the convention was 1,429 persons; attendance at the sessions indicated that others were present. The following tabulation reveals the distribution of those who were registered:

| District | Registrants |
|---|---|
| New York City and Foreign (3) | 898 |
| North Eastern (1) | 233 |
| Middle Eastern (2) | 214 |
| Great Lakes (5) | 34 |
| Canada (10) | 23 |
| Southern (4) | 13 |
| South West (7) | 12 |
| North Central (6) | 1 |
| North Western (9) | 1 |
| Total | 1,429 |

## President Skinner Urges Wider Engineering Effort

Dr. C. E. Skinner, president of the Institute, gave the address at the opening meeting of the 1932 winter convention, outlining some of the accomplishments of the Institute in the past, and pointing the way to future activities which might benefit electrical engineering as a profession and the nation as a whole. He also dwelt upon the responsibility of the engineer as a citizen, and urged greater activity in the affairs of the nation. Excerpts from Doctor Skinner's speech that relate to the more general aspects are given on p. 155 of this issue; those concerning Institute activities are quoted in the following paragraphs.

"The unusually fine program of papers before the 1932 winter convention is most satisfactory evidence that the American Institute of Electrical Engineers has been going forward during these years of depression. The winter convention, more than any other meeting of the Institute during the year, has come to be looked upon as the proper place and time to put into the record our outstanding accomplishments of the electrical industry for the year. The papers and discussions recorded at this and other meetings of the Institute constitute the history of the advances made in the electrical art in the United States, and to a considerable extent in the world. The application of electricity is without doubt the most important factor in the advance of our material civilization. It touches in some way almost every other factor which has a part in the advances which have been made during the last fifty years. Our Institute has a most enviable opportunity, supplying as it does the forum for the announcement of new discoveries, the record of achievements from year to year, and for discussion of the problems which the industry must face and find solution.

"During these last two years or more the Institute like governments, organizations, and individuals, has not been free from the effects of decreased income. This has but spurred us in an endeavor to give more service at less cost. It has been a challenge to greater efficiency in the conduct of our affairs. It has spurred us to provide, particularly in our publications, the best service to the members which can be given with the funds available. It has made necessary the limiting of the number and the length of papers presented, which is often a benefit rather than a detriment to their quality. It has spurred on the effort to carry the activities of the Institute more and more to the far flung Sections, and the eighteen or twenty Sections so far visited by your president have without exception indicated their enthusiasm and their unquestioned faith in the future of our great industry.

"This is no time to undertake expanded activities for the Institute, but it is not amiss to suggest new activities that may be planned now so as to be ready when funds will be available. It has seemed to your President that the time has arrived when an attempt should be made to write a comprehensive history of the Institute and of electrical engineering, particularly in regard to the formative years which were so fruitful of advances during the latter part of the last century. The curtain is going down for many of the players who took the chief parts in one of the greatest industrial dramas of history and much of the most interesting part of the story will be lost unless it can be written while some of these chief players are still with us. The writing of such a history would mean the collection of much data and a dramatizing and humanizing of the story as can be done by very few writers. It would seem that the American Institute of Electrical Engineers should be the body to arrange for the production of such a history if the funds could be made available and a qualified historian found.

"The Institute has been a pioneer in the standardization field, both national and international, and the recent reorganization of our standards work into the electrical standards committee should give great satisfaction to all our members interested in this subject. In the early years the standards committee of the Institute was undoubtedly the most logical and best possible means of carrying on this work, and in fact, the only place; but as the years went on, new organizations developed and new conditions arose which made it advisable to change our methods. The present plan recently adopted, largely formulated in its last stages by the late Dr. L. T. Robinson, promises to give us an entirely orderly and satisfactory procedure in the whole electrical standardization field, both national and international.

"The question of the licensing of engineers, bringing with it the necessity for a satisfactory definition of the term "engineer," and the establishment of standard qualifications by which we may be judged, has been brought about by licensing laws already passed in many States. It is of the utmost importance to all engineers that uniformity in these laws, definitions, and requirements, be established throughout the country.

"The members of the Institute, together with all other members of the engineering profession, may take some pride in the measures taken by our profession for the relief of the unemployed during this trying time of lowered industrial production. Through our local Sections, the cooperation of the groups being organized through the American Engineering Council, and through committees on unemployment, engineers as a group probably have done more for the relief of their fellow members than any other group or profession. Through our participation in the American Engineering Council we have joined in the organization of special committees in almost every State of the Union, and this action will do much to bring about greater solidarity in the engineering profession as a whole, even when this difficult time has passed. Our participation in the general work of the American Engineering Council and our joining with the plan of organizing state councils is bringing to us a greater appreciation of our responsibilities, not only as engineers but as citizens of the Republic. In times such as these, when every sort of scheme, sensible and fantastic, is before the national Congress, legislatures of the States, and even local governments, the calm considered judgment of the thinking citizen is required as never before. At this time there are before the Congress of the United States more than 12,000 bills calling for appropriations totaling approximately 30 billions of dollars, many of them with an engineering content. Another 12,000 bills are expected to be introduced before the session is over. As engineers and as citizens it is our duty as well as our privilege to take such part as we may through the American Engineering Council and its state councils, and by any other legitimate means, in giving advice as to which of these proposals are sound and which are unsound from the engineering point of view."

## Frank J. Sprague Made Honorary Member

As previously announced, (ELECTRICAL ENGINEERING Feb. 1932, p. 139-40) Dr. Frank J. Sprague, pioneer in electric traction, was elected an Honorary Member of the Institute at the meeting of the board of directors held December 4, 1931. The formal installation of Doctor Sprague as

Honorary Member was made on January 25, 1932, at the opening meeting of the Institute's winter convention. Dr. C. E. Skinner, president of the Institute, in making the installation pointed out that such membership is accorded only by unanimous vote of the board of directors and only to men of extraordinary prominence in the profession. In addition to Doctor Sprague the Institute Honorary Members now are: Andre E. Blondel, John J. Carty, Herbert Hoover, Guglielmo Marconi, Michael I. Pupin, Charles F. Scott, Motoji Shibusawa, Ambrose Swasey, and Elihu Thomson.

In Doctor Sprague's brief speech of acceptance, he addressed the audience as the apostles of speech, light, transportation, etc., so necessary to contemporary civilization. Modestly he stated that he was probably the oldest person in the room, and perhaps this tribute to him was because of his age, although he preferred to consider it to be otherwise, and to be to himself and his individual accomplishments rather than to his age.

# Edison Medal for 1931

## Presented to Dr. Edwin Wilbur Rice, Jr.

FOR "his contributions to the development of electrical systems and apparatus, and his encouragement of scientific research in industry," the Edison Medal for 1931, highest award of the A.I.E.E., has been presented to Dr. Edwin W. Rice, Jr. The presentation was made at a special session of the winter convention of the Institute, Wednesday evening, January 27, 1932. Doctor Rice is a Fellow and past-president of the Institute; he is one of the pioneers in electrical development in the United States, and has played a conspicuous part in the building up of the General Electric Company, of which he is now honorary chairman of the board. After appropriate remarks by Dr. C. E. Skinner, president of the A.I.E.E., the aims and purposes of the award were outlined briefly by Dr. D. C. Jackson, past-president of the Institute and chairman of the Edison Medal committee.

"Our Edison medalists," said Doctor Jackson, "are procreators of brilliant dyes which have worked miracles in coloring the raw fabric of civilization with the complexion of conveniences and comforts beyond the reach of kings in previous generations. These men are creators, picked and culled. . . .

"Last year, as chairman of the Edison Medal committee, I gave some history of the Edison Medal and referred to the men who joined in its founding in honor of Mr. Edison. Since then the great one whose name the medal bears has passed from his human affairs, but we shall continue to cherish his name through the years as we add to the honor roll of medalists.

"It is not altogether easy to discriminate discerningly between achievements. . . . John Ruskin once said that 'hundreds of people can talk for one who can think; but thousands can think for one who can see.' Each year, of the thousands who can think, one is to be found for the Edison medalist who also can see—one whose works prove that he can see and has seen some part of the invisible in our realm of electricity, and has brought it into full play for the glory of the culture and for the comfort of the civilized world.

**Dr. E. W. Rice, Jr.**

Recipient of the 1931 Edison Medal for "his contributions to the development of electrical systems and apparatus, and his encouragement of scientific research in industry"

"Such men are stirred by scientific curiosity and a strong discontent, a discontent even with what seems good if it may perchance be turned into better. It is the author of great works resulting from this glorious kind of discontent that we single out and acclaim on these occasions of conferring the Edison Medal. We of the American Institute of Electrical Engineers are under debt to the far-sighted founders of the medal for the privilege of administering their trust."

Following these remarks, Doctor Jackson read an address prepared by Dr. Elihu Thomson who, because of ill health, was unable to be present to speak in person. Doctor Thomson for many years has been Doctor Rice's close friend and associate; he was the man chosen to receive the first Edison Medal (1909) and was awarded the John Fritz Medal in 1916; he is an honorary member and past-president of the A.I.E.E. Excerpts from Doctor Thomson's address are given in the paragraphs which follow.

### Dr. Elihu Thomson
### Sketches Dr. Rice's Career

"It was while I was professor of chemistry and mechanics in the Boys' Central High School in Philadelphia, with Prof. Edwin J. Houston in charge of physics, that I first met Edwin Wilbur Rice as a pupil. . . . Rice entered the school in 1876 and graduated at the head of his class in 1880. What this meant in the training of a student may be illustrated thus: My class, known as the 55th, entered on examinations in 1866 about 170 strong, but of these only 18 graduated in 1870 at the completion of the four years' course. It was the same with the other classes, Rice graduating at the head of the 75th in like relation of numbers. Our relations began in the school work, in which I found him an earnest pupil, always wanting to learn, not only willing but eager to make all effort necessary for acquirement.

"When in 1880 I had decided to take up invention and electrical engineering work, Rice became a graduate, and . . . decided to associate himself with our new enterprise, practically as co-worker and assistant. With business associates, Houston and I had been carrying on work in Philadelphia. . . . On leaving Philadelphia for New Britain, Conn., where the American Electric Company had been organized to manufacture and exploit the Thomson-Houston system of arc lighting, Professor Houston's active connection with the enterprise ceased. This was in 1880, and to Rice and myself remained the task of nursing the new baby into vigorous life."

Doctor Thomson's address then outlined the difficulties experienced in the early history of this enterprise, during which time the Brush Electric Company of Cleveland, Ohio, acquired control of the American Electric Company, but later relinquished it to the "Lynn Syndicate." "I cannot say too much in praise of the invaluable assistance and perspicuous business acumen of Rice himself at this juncture," Doctor Thomson continued," for it was he who met the Lynn representatives and showed them the valuable points of the invention embodied in the Thomson-Houston system of arc lighting."

### FACTORY SUPERINTENDENT AT 22

Under the Lynn management a new and highly successful era began, and in November 1883 the manufacture was shifted to a new factory building in Lynn, Mass. Rice, then 22 years of age, was selected as plant superintendent at the new establishment.

"In his capacity of plant superintendent at Lynn (returning again to Doctor Thomson's address) an enormous amount of work fell to the lot of Rice, as the growth of the business extended into the a-c. field, incandescent lighting, and the electric railway; . . .

"It was during this period, and before the exodus which took many of our engineers from Lynn to Schenectady in 1892, as a consequence of the consolidation of the Edison General Electric with the Thomson-Houston interests under the presidency of C. A. Coffin, that our staff was enriched by the coming of the late Dr. Chas. P. Steinmetz to Lynn. . . . Rice had a leading part in securing the services of Steinmetz as a member of our technical and calculating staff at Lynn, leaving for Schenectady in 1892, or shortly thereafter. It was at this time that Rice was made technical director of the General Electric Company, a position held by him for many years, until promoted to the presidency, succeeding Mr. Coffin.

### FOUNDS RESEARCH LABORATORY

"In his position as technical director of the company, his work extended not only through the departments at Schenectady, but covered the undertakings of the several other works. . . . The responsibility was great and increasing. It was during the period of his earlier years at Schenectady that the idea of a works research laboratory was entertained. I remember receiving a letter from Rice asking my opinion of the project and requesting a statement of some of the problems which it might take in hand. In reply I pointed out the vast field covered by our ignorance, the possible solution of problems by research, and endorsed the project warmly as likely to be a great element in future technical advance.

"Thus, under Doctor Rice, the great research laboratory at Schenectady was put into action, with Doctor Whitney at the head, and such co-workers as Dr. Irving Langmuir, Dr. W. D. Coolidge, and many others, contributing through the years to its output.

"There is no space to enter into any of the details of the researches in science and technology which have been the outcome. To see a complete revolution in the field of lighting alone, we have only to point to the modern incandescent lamp with its filament of tungsten wire made by the Coolidge process and to the studies of Doctor Langmuir on the gases present in the lamp bulb. . . . The part that Doctor Rice had in this can be estimated only by such knowledge as those close to the evolutionary scene were enabled to obtain . . .

### MANY PATENTS RECEIVED

"Naturally, one so busy with electrical engineering advances has received a large number of patents in the United States. These number about 115, taken out individually or jointly with others. None the less, Doctor Rice arranged the atmosphere, so to speak, in which others could do their best work, and introduced into the organization of the industry methods which not only have benefited the company itself, but have added materially to the welfare of the employees.

"Doctor Rice's long career of attainment and usefulness naturally has brought to him many recognitions in the form of medals, honorary degrees, and decorations, both here and abroad. Doctor Rice is, I think, richly entitled to the bestowal of the Edison Medal, an honor which had Edison himself lived to know of it, would have met with his warm approval. Edison on several occasions expressed his high regard for Doctor Rice's personality and versatile ability as inventor, manufacturer, business man and financier. I think I can say for the surviving recipients of Edison medals that we are glad to endorse the action of the Edison Medal committee of the Institute in making choice of Dr. Edwin Wilbur Rice for the award on this occasion."

Presentation of the medal to Doctor Rice by President Skinner followed, after which Doctor Rice responded.

## Doctor Rice's Response Outlines Electrical History

"It is with profound pleasure," began Doctor Rice, "that I accept the Edison Medal, which I regard as the greatest of all prizes to be won by an electrical engineer. I shall treasure the medal itself as visible evidence that my work has met with the signal approval of my fellow engineers, and because of the precious memories recalled by the name and image which it carries.

"I am the first to receive this award since the death of the great man in whose honor it was established and whose name it bears; and I like to think that he would have regarded me as a worthy recipient. Among the most happy memories of my life are those of the days, all too few, which I was privileged to spend with Mr. Edison."

Doctor Rice then outlined the important developments in the field of electricity and electrical apparatus and equipment which he had observed throughout his career. These reminiscences began with his sight of a dazzling light (the arc light) at the Centennial Exposition in Philadelphia in 1876, which Doctor Rice stated was his earliest memory of anything electrical. He related seeing at the same exposition two Gramme machines, one being operated as a generator, and one as a motor. Speaking of the telephone Doctor Rice declared, "I shall never forget the thrill of my first message over the telephone. . . . I have never lost the sense of awe and wonder, that so simple a device is able to transmit and reproduce all the complex sounds, including human speech."

Doctor Rice also touched upon important inventions made by his contemporaries, including the invention of the incandescent electric lamp by Edison, Edison's experiments in the central station field, and his subsequent establishment of the first central generating station in New York. Later came the introduction of the single-phase a-c. system by William Stanley, and still later the multiphase a-c. system which at present is in almost universal use.

### EARLY ELECTRIC SYSTEMS

Speaking of some of the earlier systems which marked the development of electrical power networks Doctor Rice remarked that "all these systems were commercially successful; they grew rapidly, but were highly individualistic, even antagonistic, and were limited to their respective fields." Parallel with developments in the electric power supply and central station fields, Doctor Rice mentioned Sprague's and Van Depoele's electric trolley systems, as being really the foundation for modern electric transportation systems.

### WHAT OF THE FUTURE?

Departing from the past and present remarkable developments in the electrical art, Doctor Rice next had something to say about what might be expected of the future: "We of the engineering fraternity naturally think of the recent period as the electrical age," he said. "But these electrical and mechanical discoveries and inventions are not all. Similar progress has been made in chemistry, in biology, in astronomy, and in many other directions. . . .

"Why this sudden outburst of scientific achievement, so broad and general that our times may be aptly termed 'The Age of Applied Science?' The reason is clear: Men have found a way successfully to interrogate nature, to discover her secrets, to learn her laws, and then to put this information to practical use. Scientific research is the common name for this new tool. . . .

"No one knows the correct answer to the question as to whether or not we have reached the end of our material progress; but in view of the short time that man has used this new intellectual tool, and, moreover, when one considers the immensity and complexity of nature, it is reasonable to believe that if the same methods continue to be employed, progress also will be continuous.

"Therefore no limit is in sight, provided, and this is an important proviso, that man himself does not call a halt. The forces of ignorance, tradition, and superstition are strong and view with some alarm the progress of science. There are many who say that these new methods have been too successful, especially as applied to the field of production, and point to our great surplus of material things, to the increase in 'technological unemployment,' and all the tragic circumstances of our present depression including the paradox of poverty in the midst of plenty.

"The engineer refuses to believe that the world's troubles can be laid at his door. He places most of the blame upon the waste and extravagances of war and misdirected economic effort, to the stimulation of high pressure sales methods, the over-pledging of future wages and income, and reckless speculation in inflated values.

### Scientific Methods Must Be Continued

"While it may be admitted that there is no universal panacea and no *get well quick* cure, it would seem reasonable to expect real improvement if, for example, the same scientific methods which have been so effective in increasing production, could be brought to bear upon the problem of control and of balancing production against ultimate consumer demands. No claim is made that scientific men or engineers have a monopoly of wisdom or of brains; but it would seem that the methods which have proved so successful might be applied to the solution of the more complex social problems to the great advantage of all the people. Therefore instead of yielding to the forces of reaction, it is our duty to make strenuous effort to extend the use of the scientific method. This can be done only by education.

"Every man and woman should have the benefit of an education in the fundamental facts and methods of science. Every professional man should learn enough to understand something of the physical nature of the world, as well as of his own body. Science, in addition to creating all these new arts and new knowledge, may be accredited with something finer and more important. It has encouraged in the minds of its followers what may be called the scientific point of view.

"One who possesses this scientific point of view is inclined to be modest and tolerant of others; he searches for the truth; he hunts for facts which, if found, become his guide. He tries to see things as they exist, not as he has wished them to be; naturally he is honest with others but even more important, he is honest with himself in thought and in action. It is vitally important for our future welfare that our lawyers secure an education in science at least equal to their legal training. I single out the legal profession because the lawyer is today our political master. . . . If our legal doctors who make and interpret our laws remain ignorant of the new heaven and the new earth, what will happen to the poor bewildered common citizen.

"However, I think we may face the future with courage, as the expansion of educational facilities in recent years has been accompanied by an increase in the study of science in our schools and colleges. This may enable the new generation to meet the new problems with intelligence and success. After all, the forces of reaction and ignorance cannot prevail permanently in a country in which the voters are properly educated."

## Dr. Michael I. Pupin Receives 1932 John Fritz Medal

FOLLOWING Edison Medal presentation Wednesday evening, January 27, 1932, the 1932 John Fritz Medal was presented to Dr. Michael Idvorsky Pupin, "scientist, engineer, author, inventor of the tuning of oscillating circuits and the loading of telephone circuits by inductance coils." Doctor Pupin is an honorary member and past-president of the A.I.E.E., and was the recipient of the Edison Medal in 1920.

The John Fritz Medal is an honor awarded by sixteen representatives of the four national engineering societies: American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, American Society of Mechanical Engineers, and American Institute of Electrical Engineers. It was established in memory of John Fritz of Bethlehem, Pa., one of America's great pioneers in the iron and steel industries. The medal is of gold and is awarded not oftener than once a year for "notable scientific or industrial achievement, without restriction on account of nationality or sex."

This portion of the Wednesday night session was presided over by William S. Lee, junior past-president of the A.I.E.E. as chairman of the John Fritz Medal board of award. Mr. Lee introduced as the next speaker Bancroft Gherardi, past-president of the A.I.E.E. and vice-president and chief engineer of the American Telephone and Telegraph Company. Mr. Gherardi spoke at some length regarding the life and achievements of Doctor Pupin; his address follows.

### Mr. Gherardi Outlines Doctor Pupin's Achievements

"Fifty-eight years ago, late in the winter of 1874, a young Serbian landed at Castle Garden. He was without money or property, without friends or influence, and without knowledge of the language of this country. Many would say that he had nothing; but this would fail to recognize the things which he had. He had good health, character, ambition, a mind eager to find knowledge and to use it, and high ideals. This evening I have been selected as the spokesman of four great engineering societies whose representatives are gathered here to pay a tribute of esteem and affection to him.

"Limitations of time compel silence upon Doctor Pupin's early struggle for an education, and his studies at Columbia University, at Cambridge (England) and at the University of Berlin; except only this: that no one can read the account which he gives of this period of his life in his wonderful autobiography without being convinced that in the earlier influence of his mother, and in the period in which he was getting his education, was laid the foundation upon which rest his many achievements during a long and varied career. From the time of his connection with the staff of Columbia University, the story of his life is a continuous record of contribution to our knowledge and our methods of thought. Of these only a few high spots can be mentioned this evening.

### Invention of Loaded Telephone Line Well Timed

"Perhaps because I am a telephone engineer, I am starting by referring to his invention of the loaded telephone line. For several years prior to Doctor Pupin's work which led to his inventions and patents on this subject, it was known that the addition of continuously distributed inductance to a telephone circuit would add to the transmission efficiency of the circuit; that is to say, it would diminish the losses of the telephone current during its passage through the wires. It had been suggested that similar results should follow from the placing of inductance coils at intervals in the circuit. This had even been tried experimentally without favorable results. By means of a beautiful mathematical investigation Doctor Pupin established the fact that it was not sufficient to place inductance at intervals in the circuit, but that the inductance must be designed with reference to the circuit conditions and must be uniformly spaced at intervals having a relationship to the shortest waves which it was desired to transmit. He confirmed the results of his mathematical investigations through a brilliant series of laboratory experiments and in addition he designed and demonstrated the advantages of the toroidal type of loading coil—a design which fundamentally has persisted even to the present time, although it dates from over thirty years ago.

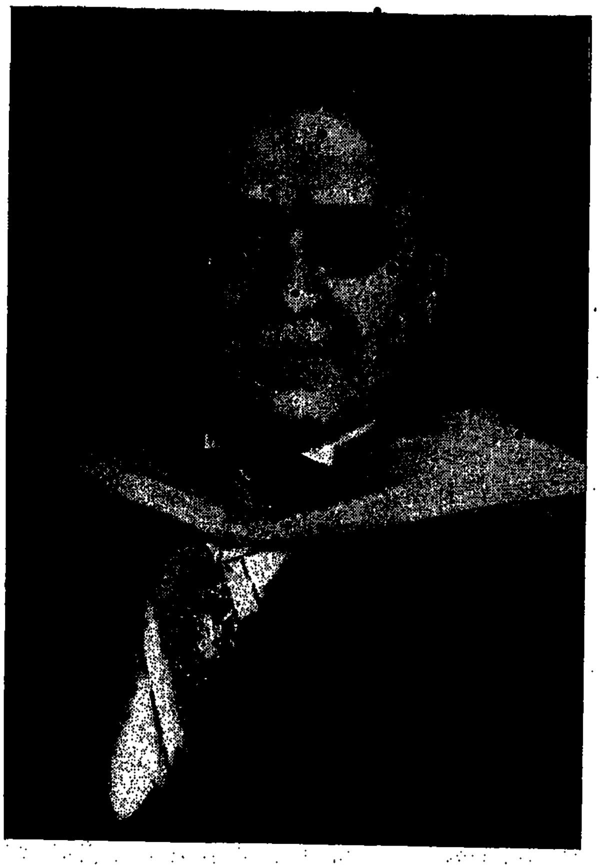
"Doctor Pupin's patents were acquired by the Bell Telephone System and from that day to this his inventions have played a fundamental part in long-distance telephony. The time at which Doctor Pupin made these inventions was most opportune: They came just when telephone engineers were confronted with serious problems in the extension of long distance telephone service over greater and greater distances, and also when, due to the unfavorable effects of non-loaded telephone cables, very serious problems were arising in the planning of long distance lines. These problems were particularly difficult where the numbers of circuits required were so great that overhead open wire constructions presented formidable difficulties, and where the lines had to be brought into large cities.

"As part of the mathematical investigation of the loading problem, Doctor Pupin developed a mathematical theory of certain forms of artificial lines or electrical networks. Such artificial lines today have numerous important applications in the communication art.

### Originated Tuned Circuit

"Doctor Pupin was the original discoverer of the electrically tuned circuit, that is, of the possibility of so proportioning the electrical characteristics of a circuit that it would respond energetically to any predetermined a-c. frequency. The electrically tuned circuit is used today in every important branch of the electrical art, in telephony, in telegraphy, in power transmission, and last but not least, in radio systems. It was first used by him and then by others in the analyzing of alternating currents, that is to say, in their separation into the different frequencies of which they were composed. In a way Doctor Pupin was unfortunate in the time in which he made this invention. At the time that he made the invention, the radio art was practically non-existent and for many years thereafter it was used only for incidental and specialized purposes. Today, however, practically every home contains an electrically tuned circuit in the radio receiving set; but Doctor Pupin's discovery was so far ahead of the development of radio and therefore of the general use of tuned circuits that few realize that, if this contribution of his were to be removed from the radio systems of the present day, they would no longer function.

"Immediately upon the discovery of the X-ray, Doctor Pupin made two important contributions. He was the first to discover the phenomenon of secondary X-ray radiation; that is, that when X-rays strike on any matter, that matter becomes itself a source of X-ray radiation. This fact was not only important in itself, but it contributed to many other scientific advances in X-ray work. Doctor Pupin did much experimental work in X-ray photography and he was, I believe, the first in this country to make an X-ray picture with the aid of a fluorescent screen. The advantage of this method over those previously used was that it enormously shortened the time necessary for the photographic exposure and made it possible to take X-ray pictures in many medical and surgical cases where, without a short exposure it would not be practicable to get an effective X-ray picture.



**Dr. M. I. Pupin**

John Fritz Medalist for 1932 with the citation of "scientist, engineer, author, inventor of the tuning of oscillating circuits and the loading of telephone circuits by inductance coils"

"Doctor Pupin was the first to suggest the use of an electrical rectifier in connection with the receiving of radio signals. While his original invention made use of an electrolytic type of rectifier cell, his invention was broad enough to cover the use of any type of rectifier element. Here again Doctor Pupin was unfortunate in that his invention was so far ahead of the development of the radio art that it was many years after his work was done before there was any extensive opportunity to use this contribution practically.

### An Educator as Well as a Scientist

"Doctor Pupin has had an important part in the building up of the scientific and engineering departments of one of our greatest educational institutions—Columbia University. He has not only contributed much in this way, but the graduates of Columbia who studied under him in many cases have made distinguished records in the fields of science and engineering. Of the many, I shall only mention two—Dr. Robert A. Millikan and Dr. Gano Dunn, a past-president of the A.I.E.E. These and many others testify with the greatest enthusiasm to what they owe to Doctor Pupin's teaching and to his inspiration.

"During the war, Doctor Pupin had an important part in starting the National Research Council. The purpose of this body as defined by President Wilson in his executive order with reference to it was: stimulating research in mathematical, physical, and biological sciences, and in the application of these sciences to engineering, agriculture, medicine, and other useful arts, with the object of increasing knowledge, of strengthening the national defense, and of contributing in other ways to the public welfare. Throughout the period of our participation in the war, Doctor Pupin devoted his abilities and his boundless energy to the vital problem of submarine detection.

### "From Immigrant to Inventor"

"No statement of Doctor Pupin's achievements, however brief, could omit the mention of his autobiography, 'From Immigrant to Inventor.' It is in itself a contribution to literature, to science, and to education, and a wonderful study in the process of Americanization. From this book many native-born Americans can learn something of the spirit and aims of our country.

"Doctor Pupin's honorary degrees, his membership in societies and his presidencies of them, his American and foreign decorations, medals and awards, are too numerous to mention; but they testify to the judgment of others as to his personality and his work. In 1921 the A.I.E.E. awarded to him the Edison Medal, the highest honor which the Institute could confer. Now three other great engineering societies, civil, mechanical, and mining, have joined with the electrical engineers in awarding to him their great joint honor.

"Doctor Pupin, I salute you: an inventor who has made important contributions to the application of electromagnetism to the uses of man; a scientist who has added important facts to our knowledge of science and contributed to scientific idealism; an educator who not only has an enviable record as to those who have studied under him, but who has advanced the cause of education; a citizen who has contributed much to this country; an American who is proud of the country of his adoption, and of whom his country is proud."

Following Mr. Gherardi's address, Mr. Lee presented the medal and certificate to Doctor Pupin with fitting remarks, to which Doctor Pupin responded as follows:

### Doctor Pupin Responds

"As I sat here," began Doctor Pupin "listening to the kind eulogy, the generous eulogy of my good friend, Bancroft Gherardi, I could not help recalling to memory some of the faces of the peasants in my native village who were my schoolmates over 65 years ago. I saw them as if in a vision, sitting right here in the front row, looking around, dazed, wondering. One of them asked me, 'Michael, how in the world did you manage it? How many saints and angels, tell us, guided you on your way from the humble pasture lands of our little village to this glorious palace of American engineers?'

"To them I answer, 'Some day I will send you a translation of the beautiful speech of Bancroft Gherardi, which will answer the question better than I can.' . . . At every point of my uphill road, I met generous encouragement. Among these, I must mention the generous encouragement of my Alma Mater, Columbia College. Without its scholarships, fellowships and facilities for scientific research work, I should have been unable to contribute even the little I have contributed in the scientific field. In fact, I wouldn't be here this evening.

"Their generous spirit is the same as the generous spirit of the John Fritz Medal board which conferred upon me this very distinguished honor. I accept it; I accept it gladly. I am proud of it and I promise that I shall always consider it as a token of the generous spirit which I met at every step in this blessed land.

"Now, my friends, permit me to change my line of thought. I have been requested to address you and deliver to you, if possible, a message from the field in which I toil as an humble worker. That field is the field of power, of heat and electrical power."

[The remainder of Doctor Pupin's address may be found on p. 156-7 of this issue.]

## Fourteen Institute Committees Hold Meetings During Winter Convention

DURING the 1932 winter convention in New York, N. Y., January 25-29, meetings were held by several of the Institute's general and technical committees. Proceedings of these meetings are summarized in the following paragraphs, except the standards committee meeting which is reported under the "Standards" department of this issue.

### STUDENT BRANCHES

Previously, this committee had been authorized to get out a booklet telling what the electrical engineer is, what he does, what type of man makes the best engineer, what qualities he should have, and what education he should be given. This was prepared with the object of giving high school students some definite information concerning electrical engineering in order to discourage those who should not go into it, and to encourage those who should. Following the distribution of two copies of this booklet to each of a selected list of 1,500 of the leading high schools in the country, requests for 12,000 copies were received, 2,000 more than the original edition.

Because of the widespread and enthusiastic approval which this booklet met, the committee at its meeting voted unanimously to ask the board of directors to authorize the printing of an additional 20,000. (The board of directors later authorized the printing of 10,000 additional copies at present.)

The second of the two most important problems discussed at this meeting was that of arranging attractive programs for the student Branches, on the subject of safety. A bibliography to be prepared by the committee and a paper by Prof. C. F. Scott on this subject, are expected to be sent to all Branches. It was proposed that one type of meeting might consist of a paper by a student on "What Safety Means in Industry," accompanied by a demonstration of the prone pressure method of resuscitation from electric shock. It was voted that the committee arrange definite plans for conducting safety instruction through the student Branches.

### TECHNICAL PROGRAM

Plans for the summer convention program were discussed by the technical program committee, and it was decided to include a session on protective devices in place of a session on application to iron and steel production, due to a conflict in date with the national convention of the Association of Iron and Steel Electrical Engineers. Also it was decided to add sessions on power generation, and on electrochemistry and electrometallurgy. The sessions which it is now planned to hold during the summer convention are: transmission and distribution, communication, automatic stations, electrical machinery, research, education, protective devices, power generation, electrochemistry and electrometallurgy, and selected subjects.

In connection with the number of pages available for printing, a discussion took place on the value of printing the technical committee reports submitted yearly by the various technical committees. It was decided that the question as to whether or not committee reports should be published, would be left to the discretion of the technical committee chairmen.

It was believed that section 89 of the by laws requiring that manuscripts of papers to be presented be received not less than ninety days before the date of presentation should be enforced, and therefore it was voted that "the manuscripts tentatively scheduled for the summer convention must be received at Institute headquarters, in complete form, by March 20, 1932, and where papers are not received those available on the docket will be substituted."

### AUTOMATIC STATIONS

The automatic stations committee decided to request allotment to this committee of one session at the coming summer convention. Among the papers available are two on operating data and experiences with automatics, and two describing new devices.

It was decided to give further consideration to revisions of standard designations. A discussion was held concerning the various automatic schemes used with communicating circuits such as supervisory control and remote indication. A subcommittee was appointed to correlate these schemes with the various forms of communicating circuits available. In considering reclosing cycles on a-c. automatic reclosing circuit breakers, it was decided to investigate the present tendency to use only one or two reclosures instead of the usual three, and the use of practically instantaneous operation on the first reclosure.

### EDUCATION

At the meeting of the committee on education, an attempt was made to determine the proper sphere of activity and responsibility of this committee. Without much guiding precedent this was a rather complicated matter, but the following five lines of activity were adopted.

Post-college education is to be encouraged at all Sections where there may seem to be need for such work. It is contemplated that the plan of post-college education proposed by Prof. Edward Bennett in 1929, and which has met with such gratifying success in the Chicago Section, be used.

Educational work for unemployed engineers is to be promoted wherever possible, in line with the plan employed at Columbia University, Ohio State University, and Massachusetts Institute of Technology, where unemployed engineers may sit in lecture courses without charge and without credit. It also was decided to urge the board of directors to encourage the work of the committee on student branches in supplying to high school students reliable information regarding engineering. The committee endorsed the work being done by the Society for the Promotion of Engineering Education in connection with summer schools for engineering teachers. The session on education to be presented at the summer convention also was discussed.

### ELECTRICAL MACHINERY

Three major items were considered at the meeting of the electrical machinery committee. A request from the standards committee, to proceed with the preparation of test codes on other apparatus similar to the transformer test code previously prepared by the transformer subcommittee, was considered. Because the purpose of this test code is to enable operators and others not familiar with electrical design to carry out tests on electrical machines, the subcommittees on synchronous, induction, and d-c. machines were asked to prepare test codes in their respective fields. These will supplement present standards.

Technical programs for the Providence meeting and the Cleveland convention were discussed, and plans were made for one session on electrical machinery at each.

The practise of surge voltage testing of transformers is now general, but because of the many difficulties in specifying test conditions and requirements to be fulfilled no standards have been prepared on this subject. It was the opinion of the committee that the formulation of such standards should now be attempted, and the transformer subcommittee therefore is planning to undertake this work in the immediate future.

### ELECTROCHEMISTRY AND ELECTROMETALLURGY

At the meeting of the committee on electrochemistry and electrometallurgy, papers for presentation at the summer convention were considered and suggestions offered both as to the papers to be presented and the material which might advisably be included in them.

The desirability was considered of securing the cooperation of the Institute in plans now in process of formation by the American Electrochemical Society for a Faraday centennial ceremony to be held during the World's Fair in Chicago in 1933. The organization of the membership along more effective lines also was considered, and it was decided to obtain the written comments of each member before submitting recommendations to the directors.

### ELECTROPHYSICS

Three matters were taken up at the meeting of the committee on electrophysics. First, there was a discussion of the general matter of the definition of electric and magnetic units, and of systems of units. The electrophysics committee has taken no formal action in this matter, of course, but has sent a communication to the standards committee. At the present time there is much active work under way on this subject on various organizations. Second, the general manner of reviewing of papers was discussed. Third, the committee discussed the general subject of the extent to which papers on electrophysics are being secured prompt and effective publication in the A.I.E.E. publications.

### INSTRUMENTS AND MEASUREMENTS

At the meeting of the committee on instruments and measurements, the activities of the subcommittees were reported and record made of the fact that the subcommittee on recording-instrument standards had completed its work. These standards were submitted to the standards committee for adoption. Similar action also had been taken in the case of the standard set of definitions dealing with telemetering.

A previously arranged joint meeting with the subcommittee on definitions for instruments and testing also was held. A considerable part of this meeting was concerned with a discussion of proposed changes in these definitions, and the authorization of a special subcommittee to act for the instruments and measurement committee so that the work on definitions of instruments and testing could be concluded as speedily as possible.

### POWER GENERATION

The committee on power generation received the reports of several subcommittees, and discussed plans under way for the preparation of papers for presentation at the coming summer convention. The recent notable progress in the use of high temperature and high pressure steam was reviewed and a paper now being prepared was discussed with special reference to modern methods of fabrication in which electricity played an important part. Power system interconnection was discussed, and it was pointed out that the main dearth of information now lies in papers describing the actual operating experience of large interconnected systems. Other papers also now are under preparation on the subjects of recent trends in power plant design and hydroelectric development. Further, a symposium is being prepared on the features of power station and system operation that contribute to the economy and reliability in the service rendered by several power systems.

Methods for securing continuity in the work of the committee were discussed, and for this purpose the drafting of an interim progress report for 1932, rather than the customary complete survey of current progress in power generation normally made at intervals of two years, was considered.

### POWER TRANSMISSION AND DISTRIBUTION

Reports from the various subcommittees were received first at the meeting of the power transmission and distribution committee. The present set-up of subcommittees was approved. The sessions to be held and papers to be presented at the next few meetings and conventions of the Institute were discussed, and papers for several of these definitely selected. For the summer convention the question was raised as to whether the session should be devoted to papers on lightning, or to papers on mechanical features of transmission systems, particularly conductor vibration. Since several sessions have been devoted to lightning during the past few years, while the mechanical features have been neglected, it was decided to devote the session to conductor vibration.

A general report on transmission and distribution in the United States is being prepared by members of this committee, for presentation at the International Electrical Congress in Paris, France, this summer, and it was brought out that this is to be a comprehensive report and should be of considerable reference value.

### TRANSPORTATION

A list of papers proposed for future technical sessions was discussed at some length during the meeting of the transportation committee. Following that, the chief discussion centered on the question of requirements for motive power. It was agreed that this is a most important subject, and one which had been touched upon very slightly in Institute meetings. It was suggested also that the subject be broadened to include track maintenance as a function of axle loadings and other features, and to include design of motive power. A suggestion was made that the subject might be developed by means of a questionnaire, possibly in cooperation with the engineering division of the American Electric Railway Association.

### Transmission Towers and Conductors

An independent meeting of the subcommittee on steel transmission towers and conductors was held, taking the form of an annual gathering in which reports from different groups in the subcommittee were read. Some of the recent developments in theory and practise in connection with transmission towers and conductors were discussed, including the possibilities of covering these subjects in technical papers. Some of these subjects, although not actively followed by the subcommittee, have been checked from time to time to see that they get their due publicity, it being the aim of this subcommittee to foster as far as possible the writing and presentation of papers dealing with subjects that are of present day interest.

Among the subjects discussed were the development of hinged crossarms on steel towers, the investigation of embrittlement of hot-dipped galvanized steel, a new straight-line column formula, and a proposal for the drafting of requirements for modern steel tower lines as regards clearances and electrical characteristics The present status of studies of vibration of electrical conductors was reviewed.

### Lightning and Insulators

At the meeting of the lightning and insulator subcommittee of the power transmission and distribution committee, the three preferred impulse test waves (½×5, 1×10, and 1½×40 microsec.), previously adopted by the committee, were discussed and the following agreements reached.

1. These three waves are to be recommended for use in securing impulse data on insulators and insulation.
2. These waves could be secured without difficulty in any recognized laboratory today.
3. It was advisable for the laboratory making impulse tests to check the impulse wave obtained from the oscillograph with the calculated wave.
4. In all cases, impulse data given out to the engineering field should be accompanied by a record of the actual wave used in test.

It is believed that the above procedure will greatly clarify the present situation and enable those who use impulse data to obtain similar information from all manufacturers and compare and use it on an intelligent basis. The committee plans to put complete recommendations on preferred impulse test waves, general methods of tests, etc., in the form of a paper for presentation in the near future.

Past discrepancies in 60-cycle flashover of insulators were found to be due to different humidities at the time of tests. Correction for this feature brings flashover values within reasonable agreement.

The desirability of using the same impulse wave for insulation testing as for lightning arrester testing is recognized; but since the test conditions on arresters are inherently different from those on insulation, it was agreed that no logical basis for using the same impulse waves for both types of test exists.

It was agreed that the impulse characteristics of protective or coordinating gaps, should be obtained; and it was believed that this information would become available when similar information on bushings is obtained and made public.

The beneficial effects indicated by the use of the so-called counterpoise in reducing lightning troubles on transmission lines were discussed. The limited number of such installations is being closely followed, but further experience is necessary before final conclusions are made.

## Great Lakes District Meeting

Arrangements essentially have been completed by the local committee for the three-day meeting of the A.I.E.E. Great Lakes District to be held at Milwaukee, Wis., March 14-16, 1932, with headquarters in The New Pfister Hotel. A tentative technical program and information about hotel rates were published in Electrical Engineering, February 1932, p. 133. The few minor changes in the tentative technical program made since the first announcement are outlined in the following paragraph.

"Normal Frequency Arcover Values As Affected by Size and Humidity" by H. A. Frey and K. A. Hawley, Locke Insulator Corporation, has been added to the Wednesday morning session. The paper on "Factors Affecting Sparkover of Insulators and Bushings" by W. L. Lloyd, General Electric Company, formerly scheduled in the Tuesday morning session, has been transferred to the Wednesday morning session to bring together all of the papers on insulator sparkover. To make room for these and keep the number of papers per session nearly uniform, the two papers on mercury arc rectifiers were transferred to the Tuesday morning session.

A student session also will be held on Monday at 2 p.m. and selected papers will be presented by students of the Great Lakes District.

## Research Assistantships Offered by U. of Illinois

To assist in the conduct of engineering research and to extend and strengthen the field of its graduate work in engineering, the University of Illinois maintains fourteen research graduate assistantships in its engineering experiment station. Two other such assistantships have been established under the patronage of the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $600 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics, or applied chemistry.

Appointments are made and must be accepted for two consecutive collegiate years of ten months each, at the expiration of which period, if all requirements have been met, the degree of Master of Science will be conferred. Half of the time of a research graduate assistant (approximately 900 clock hours for each ten-month period) is required in connection with the work of the department to which he is assigned.

Nominations to these positions, accompanied by assignments to special departments of the engineering experiment station, are made from applications received by the director of the station each year not later than the first day of April. Preference is given those applicants who have had some practical engineering experience following the completion of undergraduate work. Appointments are made in the spring, and become effective the first day of the following September. Research work and graduate study may be undertaken in architecture, architectural engineering, ceramic engineering, chemistry, civil engineering, electrical engineering, mechanical engineering, mining engineering, municipal and sanitary engineering, physics, railway engineering, and theoretical and applied mechanics. Additional information may be obtained by addressing The Director, Engineering Experiment Station, University of Illinois, Urbana, Illinois.

**Illuminating Engineers Convention Announced.**—The twenty-sixth annual convention of the Illuminating Engineering Society has been announced for the week of September 26, 1932, and is to be held at the New Ocean House, Swampscott, Mass. Officers of the society are; *president*, J. Daniels, Boston, Mass.; *vice-presidents*: J. W. Barker (F'30) New York, N. Y. and J. L. Stair, Chicago, Ill.; *general secretary*: E. H. Hobbie, New York, N. Y.; and *treasurer*, A. L. Powell, New York, N. Y.

# F. L. Hutchinson Succumbs to Heart Failure

AN UNTIMELY END came to a noble career when death stilled the courageous, fighting heart of F. L. Hutchinson, well beloved national secretary of the Institute, at 12:30 a.m., Feb. 26, 1932. Literally a martyr to the cause of his chosen life work, Mr. Hutchinson gave to Institute problems so generously of his indefatigable energies that he was unable to withstand the attack of heart trouble which finally took its fatal toll. The membership of the Institute has lost a leader militant in the defense of its best interests; the officers an able and willing team mate; the staff a kindly, keenly alert, inspiring taskmaster; and his family a devoted companion.

### EARLY EXPERIENCE

Frederick Lane Hutchinson was born in Elizabeth, N. J., April 2, 1866. He began his business experience in the service of the Pennsylvania Railroad Company in one of its principal offices in New York City, where he had several years' experience in accounts, correspondence, and general office work. In 1889 he entered Cornell University and was graduated from the electrical engineering course in 1893, when he entered the employ of the Westinghouse Electric and Manufacturing Company. After several years' experience in the manufacturing, testing, engineering, and sales departments in Newark, N. J., New York City, and Pittsburgh, Pa., he was transferred to the publication department, where for several years he was employed in preparing the technical literature of the Westinghouse company.

In 1901 he became manager of the publication department of the C. W. Hunt Company, New York, and in the following year became advertising manager of the National Electric Company of Milwaukee, Wis. A year later he was made manager of electrical sales for the same company.

### A.I.E.E. WORK

In 1904 Mr. Hutchinson returned to New York and undertook some special work on the Transactions of the American Institute of Electrical Engineers. Gradually the scope of his work was increased until, in February 1908, upon recommendation of Secretary Ralph W. Pope, he was appointed assistant secretary. Upon Secretary Pope's resignation after 27 years of service with the Institute, Mr. Hutchinson was, in August 1911, appointed acting secretary by the board of directors. On January 12, 1912, the board of directors of the Institute unanimously appointed him national secretary, upon the unanimous recommendation of the Institute's secretary committee.

FREDERICK LANE HUTCHINSON
1866-1932

Mr. Hutchinson became an Associate of the Institute in 1894 and was transferred to the grade of Member in 1913. He was thoroughly familiar with the history and policies of the Institute, the scope and duties of its numerous committees and representatives, and the relations of the Institute to other engineering and similar organizations, both in this country and abroad. He was one of the delegates of the Institute to the World Power Conference, London, 1924, and to the World Engineering Congress, Tokyo, 1929. He served as a member of various Institute committees, both before and after he became secretary. Immediately prior to his death he was a member of committees having supervision of several important activities, including publications, coordination of Institute activities, award of Edison Medal, and maintenance of Institute headquarters. Mr. Hutchinson also was a representative of the Institute on the Assembly of American Engineering Council, the division of engineering and industrial research of the National Research Council, and on the Engineering Societies Library Board. He was an enthusiastic worker for the development of the engineer and for the enhancement of the engineering profession, and was identified with various joint endeavors of the national engineering societies and allied organizations the efforts of which were directed toward that end.

### INSTITUTE GREW RAPIDLY

His long experience as assistant secretary particularly qualified him for the duties of secretary. At the time of his appointment the Institute had little more than one-third of its present membership, and its rapid growth and increasing activities made growing demands upon the secretary's office, in meeting which Mr. Hutchinson displayed marked executive ability. He combined a very pleasing personality with a highly judicial temperament. With characteristic energy he mastered every phase of the Institute's activities, and the directors and governing committees of the Institute came to defer more and more to his judgment in all matters of Institute management. To every suggestion for the improvement of the Institute or changes in its policy he accorded a careful and impartial consideration, and the fairness of his decisions gained the respect and confidence of all with whom he dealt.

As the work of the Institute increased, Mr. Hutchinson gradually built up a small staff of assistants to whom he was the guide and inspiration. He inaugurated a series of monthly office conferences at which reports of each of the departments were presented and discussed. These conferences were marked by the utmost frankness and cordiality, and Mr. Hutchinson's leadership encouraged the enthusiastic cooperation of his business associates.

In addition to his Institute membership Mr. Hutchinson was a member of the American Association for the Advancement of Science, the American Sociological Society, and the American Academy of Political and Social Science. Mr. Hutchinson also was a member of the Engineers' Club of New York, and of the Cornell University Club of New York.

Mr. Hutchinson's last illness really started prior to the recent winter convention. For two weeks he was down with a severe case of grippe from which he had not recovered when he returned to his office to take part in the rush of convention activities. Indomitable, he remained at his post until February 8, then to return to his sick-bed never to leave it alive.

## F. L. Hutchinson as Seen by Some of Those with Whom He Has Worked

CHARLES F. SCOTT (A'92, F'25, HM'29, president 1902-3)—Since Mr. Hutchinson entered Secretary Pope's office as an assistant nearly 30 years ago the Institute membership has increased from 1,800 to 18,000 and its activities have increased in like ratio. In this development he has been a quiet, constructive force. As secretary for a score of years he has shown rare tact and skill in carrying out the policies and instructions of presidents and boards, while exercising his own good judgment and impressing his own ideas. While other officers have come and gone he has been a continuing, directive, creative factor in the development of the Institute. He was a wide reader and student of affairs, interested in economic trends and social evolution, with high ideals of the responsibilities of the engineer as citizen. I realize the loss to our electrical group, and to the engineering profession. But to me there comes a keen sense of personal loss in the passing of my long-time associate and sympathetic friend. His enlarging vision and progressive ideals engendered increasing appreciation and regard. How deep these were I did not fully realize until the shock of the telegram announcing his death.

M. I. PUPIN, (A'90, F'15, HM'28, president 1925-6)—I have just received the sad news of the death of our national secretary. It is shocking news; it will cast a deep shadow of sadness over our beloved Institute, just as it has cast it over me. His death is an irreparable loss to the Institute and to all its friends and his friends. I am one of them. While president of the Institute I met Mr. Hutchinson often and got to know him quite intimately. I always admired him and loved him, and when I got to know him more intimately I admired him and loved him even more. He was a loyal servant of the Institute and one of its most devoted members. His memory will live long in the hearts of our Institute membership and it will be the memory of the most distinguished servant of the Institute.

GANO DUNN (A'91, F'12, president 1911-12)—F. L. Hutchinson was a great Secretary. As assistant to his beloved predecessor, Ralph W. Pope, a fine loyalty long concealed his abilities. Upon Mr. Pope's elevation to the Honorary Secretaryship, during my presidency in 1911-12, the country was scoured for a "big man" appropriate to the Institute's growth and increasing importance, but a trial period of a few months quickly discovered that we already possessed him. We were in the position of the mariners dying of thirst off the mouth of the Amazon, who were signaled to cast their buckets overboard. Hutchinson was an organization statesman whom the title of National Secretary did not adequately describe. His capacity for self-effacing leadership under successive presidencies of one-year terms contributed in unmeasured degree to developing the usefulness of the American Institute of Electrical Engineers to her members and the public, and to establishing her high rank in the respect of her sister societies and the engineering profession throughout the world. Solving his problems by methods that were creative and constructive, rather than controversial or regulatory, he knew the value of goodwill and cooperation untainted by self-interest. His word was his bond and his personality radiated humor and trustworthiness. Our Institute has lost her focus and thousands of her members a dear friend.

FRANK B. JEWETT (A'03, F'12, president 1922-3)—In the death of F. L. Hutchinson, the electrical engineering profession in America has lost much more than the services of a highly efficient and effective secretary. To many members of the Institute the news of his death will bring pangs of poignant grief in the knowledge that they have lost a sincere, kindly, and always helpful friend. For nearly two decades the development and growth of the Institute to its present position as one of the great engineering societies of the world has been very largely influenced by Mr. Hutchinson. During his occupancy of the secretarial office, presidents, no two of them alike in their methods or purposes have come and gone in a continuing procession. To one and all Mr. Hutchinson proved to be a sound and discriminating counselor whose advice has insured the avoidance of many a pitfall. Probably none of us appreciate fully the extent to which this quiet, unobtrusive, but forceful man has been the guiding force which has directed the course of the Institute in new and uncharted waters or through the turbulent seas of potential discord which are always present when many men of many minds meet for discussion and action. Never seeking to take the center of the stage even when his greater familiarity with and understanding of some situation would have made this easily possible, he nevertheless always, in his quiet way, offered exactly the right suggestion at exactly the right time. Many a brilliant piece of work for which someone else was acclaimed the author was in the last analysis the embodiment of his mature conclusions.

W. S. LEE (A'04, F'13, president 1930-1)—It is with a sense of deep personal loss that I learn of the death of F. L. Hutchinson. My close association with him during my term as president of the Institute afforded me an opportunity of knowing him intimately and of observing and appreciating his zeal and enthusiasm for the work of our organization and his indefatigable industry in its behalf. Not only was Mr. Hutchinson zealous in the cause of his own organization, but he was always ready and effective in his cooperation with other engineering and business organizations, and with the public in general. His ability to bring about effective coordination between our own and other organizations was unusual, reflecting not only the real capacity of the man but an earnestness of purpose and a sincerity that commanded the respect and admiration of all who knew him. In his passing not only the Institute but the engineering profession generally and the public have sustained a severe loss.

C. E. SKINNER (A'99, F'12, president 1931-2)—I was shocked beyond measure to learn of the death of National Secretary F. L. Hutchinson. The Institute has suffered an irreparable loss in his passing. For many years, as administrations came and went, Mr. Hutchinson has been the real guiding spirit of the Institute. To him far more than any other individual the Institute owes its present position among the national associations of the United States. He handled all of its relations with outstanding wisdom and unfailing tact. He was universally respected and admired by all who knew him whether it be through official contact or through mere personal acquaintanceship. Presidents and boards of the Institute have depended upon him and have placed implicit confidence in his execution of the exacting duties of his office. His death comes as a great personal loss to me as it must to every member of the Institute who has ever made his acquaintance.

C. W. RICE (A'97, F'12, secretary A.S.M.E.)—Mr. Hutchinson's contribution to every situation was constructive, broad-gaged and progressive. With an intimate, almost daily, association since 1904 when he first took up the work of the Institute, I cannot remember a single instance where he took a position with respect to any subject that was not favorable to the accomplishment of the highest purpose of the project in hand. He was particularly able in clearing up a situation and had the invaluable habit of putting the matter under discussion in such shape that the group could act. In this process he gave his opinion with such courtesy that one could differ and the discussion be absolutely impersonal. Then, with absolute mental honesty and unselfishness, he would phrase the consensus of opinion even though not with his own approval. Every member of the Institute and every engineer with whom he ever came in contact will join in the tribute that Mr. Hutchinson directly contributed to the enhancement of the prestige of the profession and by so doing advanced the influence of the Institute.

## Directors Meet During Winter Convention

The regular meeting of the board of directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, N. Y., January 27, 1932.

There were present: *President*—C. E. Skinner, East Pittsburgh, Pa. *Past-president*—W. S. Lee, Charlotte, N. C. *Vice-presidents*—H. V. Carpenter, Pullman, Wash.; H. P. Charlesworth, New York, N. Y.; L. B. Chubbuck, Hamilton, Ont.; W. B. Kouwenhoven, Baltimore, Md.; I. E. Moultrop, Boston, Mass.; and G. C. Shaad, Lawrence, Kans. *Directors*—A. E. Bettis, Kansas City, Mo.; L. W. Chubb, East Pittsburgh, Pa.; A. B. Cooper, Toronto, Ont.; A. E. Knowlton, New York, N. Y.; A. M. MacCutcheon, Cleveland, Ohio; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, New York, N. Y. *National treasurer*—W. I. Slichter. *National secretary*—F. L. Hutchinson, New York, N. Y.

The minutes of the meeting of December 4, 1931, were approved.

Reports of meetings of the board of examiners held December 22, 1931, and January 20, 1932, were presented and approved. Upon the recommendation of the board of examiners, the following actions were taken on applications pending: 260 Students were enrolled; 413 applicants were elected to the grade of Associate; 13 applicants were elected to the grade of Member; 26 were transferred to the grade of Member and one was transferred to the grade of Fellow.

In accordance with a suggestion adopted at the conference of officers, delegates, and members held in June 1931, and upon the recommendation of the committee on coordination of institute activities, the board voted to take the following actions:

1. The appointment of a national standing committee on transfers, composed of five Fellows and Members and including at least one member of the board of examiners, to prepare literature which will encourage members of the Institute who are fully qualified for the higher grades to submit their applications, and to coordinate the activities of the Sections in connection with transfers.

2. The encouragement of the appointment by each Section of a suitable committee to study the qualifications of its members and to urge those who are fully qualified for higher grades to apply for transfer.

### 1933 Meeting Schedule Adopted

A schedule of meetings for the calendar year of 1933, prepared by the committee on coordination of Institute activities, and including all requests for meetings that had been received by the committee, was adopted, as follows: January, winter convention, New York, N. Y.; May, North Eastern District meeting, Schenectady, N. Y.; June 26-30, summer convention, Chicago, Ill.; Aug. or Sept., Pacific Coast convention, Salt Lake City, Utah; Oct. or Nov., South West District meeting, St. Louis, Mo.

The rules governing the award of national and district prizes were amended to provide for competition for both the national and district prizes for initial paper by graduate students who are members or enrolled Students of the Institute.

Sec. 34 of the by-laws was amended to read as follows (the amendment consists of the addition of the words "having three or more Branches"):

> Sec. 34. To facilitate cooperation among the Student Branches, there shall be a committee on Student activities in each geographical district having three or more Branches, consisting of the vice-president, District secretary, and the counselors of all Branches within the District. The committee shall elect one of the counselors as its chairman, and may elect such other officers as it deems desirable.

Approval was given to the dates, October 10-13, of the Middle Eastern District meeting to be held in Baltimore in 1932.

The board approved amendments to the by-laws of the Lamme Medal committee, providing for a change from October 1 to November 1, each year, in the closing date for receipt at Institute headquarters of nominations for the medal.

Upon the recommendation of the standards committee, the following actions were taken:

Voted to relinquish the Institute's joint sponsorship of the sectional committee on wires and cables in favor of a single sponsorship under the electrical standards committee.

Approved the recommendation of the American Standards Association that the title of A.I.E.E. Pamphlet No. 100 be changed to "Recommended Practise in the Temperature Operation of Transformers."

Approved, as joint sponsor, a report of the sectional committee on radio on "Standard Vacuum Tube Base and Socket Dimensions" and "Manufacturing Standards Applying to Broadcast Receivers."

A report of a joint committee of engineering societies appointed to consider the question of the desirability of the organization of state engineering councils was presented, and upon the recommendation of this committee the board approved the general idea of encouraging the formation of state councils of professional engineers.

The president was authorized to appoint two representatives of the Institute on the council of the American Association for the Advancement of Science for the year 1932, and to appoint delegates to attend the annual meeting of the American Academy of Political and Social Science, Philadelphia, Pa., April 15-16, 1932.

Other matters were discussed, reference to which may be found in this and future issues of Electrical Engineering.

## A.E.C. Urges More State Councils

At the annual meeting of the assembly of the American Engineering Council in Washington, D. C. January 14-16, 1932, the assembly voted to adopt the following recommendations made by a joint committee composed of representatives of the American Society of Civil Engineers, The American Society of Mechanical Engineers, American Institute of Electrical Engineers, and American Engineering Council, relative to the further formation of state engineering councils:

1. It is deemed essential for the advancement of the engineering profession that there be organized a state council of professional engineers in each state in which such a council does not already exist.

2. Each state council should be composed of representatives of the local sections of national engineering societies and the engineering and allied technical societies within the state.

3. The purpose of these councils should be to enable the engineering and allied technical organizations to render a more effective public service, and to contribute to the advancement of these professions. They may through appropriate channels communicate to the proper representatives of the state governments advice and suggestions relative to questions of legislation or administration and in the solution of which engineering and allied technical knowledge and experience may be involved or valuable, and may upon the request of local or regional organizations or in the absence of such organizations, render similar service in local affairs.

4. Membership in these councils should consist of any society or organization of the engineering or allied technical professions within the state whose chief object is the advancement of the knowledge and practise of engineering or of allied sciences, or the promotion of the interests of engineering or allied technical professions and which is not organized for commercial purposes. Membership in these councils should not be granted to individuals.

## Providence Meeting Plans Progressing

In addition to the student sessions on Friday, May 6, 1932, the meeting of the Institute's North Eastern District, No. 1, to be held in Providence, R. I., May 4-7, 1932, will include four technical sessions. The symposium on "Traffic Control Systems" will attract considerable attention. Other sessions will be sponsored by the machinery, and transmission and distribution committees, and at the fourth session there will be presented several selected papers of general interest.

The dinner will be held Thursday evening, May 5. Also a wide range of inspection trips has been planned by the local committee. Headquarters will be at the Providence-Biltmore Hotel. Further details of this District meeting will be given in the April issue of Electrical Engineering.

# Unemployment Relief Being Afforded by Institute and Other Engineering Groups

UPON the recommendation of the Institute's committee on the economic status of the engineer, the board of directors unanimously adopted a resolution at a meeting held in Kansas City, Mo., October 23, 1931, providing for unemployment relief. As reported on p. 975 of ELECTRICAL ENGINEERING for December 1931, this resolution recommended that each Section formulate and carry out a plan of relief embodying substantially the following features: That in each locality a committee of engineers be organized, composed preferably of representatives of all the engineering groups in the community and working in close cooperation with local sections of other societies and engineering groups, and so organized as to work in close cooperation with other local civic relief organizations. Further recommendations regarding organization were made, and it was suggested that these local committees conduct surveys of the need for relief and for local opportunities for constructive work or employment, using so far as possible the aid of engineers at present unemployed. Further, it would be the purpose of this committee to collect and administer funds for loans and remuneration to deserving unemployed engineers, and to perform such other duties as might be deemed advisable in each particular community.

### SECTION ACTIVITIES SUMMARIZED

In response to this resolution, letters were written to each Section urging the consideration of organizing, in conjunction with other engineering groups, an engineers' unemployment relief committee. As the conditions in different communities vary widely, it is difficult to generalize upon the results which have been obtained. In some communities unemployment among professional engineers has been widespread, and much work has been done by the committee in alleviating this condition. In other sections, particularly those far from manufacturing centers, the situation has not been acute, and frequently the local civic unemployment relief organization has been considered adequate.

In those localities where relief work has been undertaken, the methods of attack vary widely. In certain communities the local situation has been such that the Section of the Institute has taken full responsibility for collection of funds and other relief work among the electrical engineers of the district. The San Francisco Section of the Institute has reached the conclusion that financial aid in the form of loans is the most effective means of relief for the conditions found in their particular district, and are concentrating on this form of activity. The Boston Society of Architects and the engineering societies of Boston, Mass., are cooperating in the collection of funds to be distributed as salaries to unemployed members of the profession who assist in emergency planning and research work to be used "in the advancement of city planning and regional data, in suggestions for rehabilitation of depreciated properties and districts, for the elimination of slums, for the long-range planning of the physical development of our various municipal departments, in economic surveys of various kinds, valuations or appraisals for various purposes, and in other similar projects."

More frequently, the Section cooperates actively with other relief bodies and places its special emphasis upon assisting the electrical engineer. Questionnaires have been sent out by many Sections and registration of those unemployed undertaken. Industries have been canvassed in an attempt to learn of positions available and the qualifications essential in filling these. A particularly valuable part of the work undertaken is a study of the fitness of the man for the position open and the economic necessity for aiding each individual. Considerable effort has been made to promote emergency work to be undertaken by the local and State governments; and toward the adoption of the scheme of spreading work as far as possible among the largest numbers of men, both in government and industrial activities. Among the Sections of the Institute which have been particularly active are, Atlanta, Boston, Chicago, Cincinnati, Cleveland, Connecticut, Dallas, Denver, Detroit-Ann Arbor, Ft. Wayne, Los Angeles, Milwaukee, Minnesota, Philadelphia, Portland, Rochester, San Francisco and Seattle.

Surveys have been conducted by practically all Sections of the Institute. Some of these indicate that there is very little unemployment among electrical engineers in the Section. Also, the surveys indicate that the largest part of the unemployed are young men, few of them with dependents, and most of them having homes to which they may return. Educational communities, especially, appear to be free from an acute unemployment situation, and in general it appears that throughout the country electrical engineers have not been so adversely affected as many other engineering and non-engineering groups.

### NEW YORK CITY PLAN

Perhaps the most thorough and complete scheme for coping with the immediate unemployment problem is that developed in New York, N. Y., for the metropolitan district. A very definite method of procedure in collecting and distributing funds and otherwise providing unemployment relief has been set up and is functioning to aid a very large number of persons. As the details of this plan may be of assistance to other communities, space will be given here for its description.

Action was initiated by the American Society of Civil Engineers to form a committee to aid unemployment among engineers in this district. As a result of this action, the first meeting of the Professional Engineers Committee on Unemployment, known in New York as the P.E.C.U., was held October 21, 1931, with representatives from the four national societies of civil, mining, mechanical, and electrical engineers present. At this meeting it was decided that the engineering profession should carry on its own unemployment relief program. This decision was reached because the regularly constituted relief agencies in the New York City region held to an exceedingly rigorous standard of destitution, and further because part of the program was to prevent, so far as possible, members of the engineering profession from reaching this condition.

Later it developed also that it was exceedingly difficult to obtain information from those in need of relief. Engineers as a class have never been given to talking of their troubles. However, it was found that these men would speak more freely to another engineer than to a professional social worker.

A general committee of about 40 members consisting of engineers prominent in the profession, whose names were ample evidence of the high character of the undertaking, was immediately formed. This general committee, under the chairmanship of H. de B. Parsons, appointed an executive committee of six men with J. P. H. Perry, chairman, to carry on actively the work of soliciting funds and of unemployment relief. This committee directs some dozen standing committees, which are divided roughly into two groups: those subsidiary to a finance committee, chiefly concerned with the collecting of funds; and those working under a relief committee, providing direct relief in such forms as employment, loans, legal aid, and engineering education.

### ENGINEERS CANVASSED TO OBTAIN BASIC DATA

The first step was to register the unemployed engineers in order to get an accurate estimate of the problem with which the committee was confronted. A postcard was first sent out to the metropolitan membership of the four societies advising them of the formation of the committee, stating that its object was to devise methods by which engineers in need of assistance would be looked after by their brothers in the profession, and also advising members in a position to do so to be prepared to contribute to the movement.

A tentative organization was formed, headquarters established in the Engineering Societies Building, New York, and preparations made to register the engineers as soon as they came in. At a mass meeting held in the Engineering Auditorium on November 9, 1931, prominent speakers outlined the program to be carried out and also called for suggestions. The notice of the meeting carried this paragraph: "If you are unemployed and in need of assistance we urge you to register in person before November 10, at Room 201, 29 West 39th Street, New York City." Registration was very slow at first but increased rapidly from day to day as the movement gathered impetus.

Two policies were stated definitely at the beginning of the movement: (1) that the P.E.C.U. in affording relief would make no distinction between members and non-members of the four engineering societies; and (2) that all money collected for relief should be applied to relief purposes only, the necessary administrative funds to be obtained from other sources.

Subsequently, however, the demands placed upon the committee required a change in the policy regarding relief to unemployed engineers regardless of whether such engineers were members or non-members of the four societies. At a meeting of the executive committee on February 8, 1932, it was decided that with respect to placement of unemployed engineers on P.E.C.U. payrolls only members or former members of the four societies could be considered. However, in the case of placement of unemployed engineers on the payrolls of public organizations the present policy of assisting both members and non-members would be continued. Loans are to be made only to members or former members of the four societies. It was felt that these changes were justified by the fact that contributions have been made entirely by the membership of the four societies.

From the very first, the executive committee of the P.E.C.U. recognized that its problem from an administrative point of view was relatively more difficult than that confronting the great city committees the principal duty of which was to collect funds. Once funds were collected by such committees they were turned over to the organized charities of the city for distribution. The P.E.C.U., however, had not only to collect the money, but also to build up an organization composed wholly of engineers who were largely volunteer workers and also entirely inexperienced in social welfare work. The problem was one of organizing to spend the money with justice but leaving no loophole for scandal. Great care has been exercised in safeguarding the expenditure of this money, not only in making just loans, but in handling payrolls carefully.

### "MADE WORK" BUREAU ESTABLISHED

One of the first steps was to make contact with the regularly established relief organization, which is the New York branch of the President's Organization on Unemployment Relief, and which had already established a "made work" bureau. The officials of the latter organization because of the obvious advantages of such aid accepted the offer of having this "made work" carried out with proper engineering supervision; however, because the destitution requirements of these regularly appointed agencies were such that many engineer applicants in need of help were unable to qualify, the P.E.C.U. established its own "made work" bureau.

### ORGANIZATION OF ENGINEERS DEVELOPED

The organization of the P.E.C.U. was developed by a gradual process to its present stage. In addition to the general and executive committees already mentioned, is a committee on clearance, its chief duty being to maintain contacts with existing relief agencies; a committee on organization to take care of problems of internal administration and to act as a comptroller of the administration funds; and a publicity committee. The remainder of the work is divided into two groups, financial and relief.

The work of the finance committee is concerned with the raising of funds for relief purposes only. So far, this has been done by appeals to the metropolitan district members of the four engineering societies, principally by letter. A special list of engineers believed to be able to make sizeable contributions has been approached by direct solicitation. Money collected by the finance committee is deposited with United Engineering Trustees, Inc., which acts as the treasurer of the P.E.C.U. There are many obvious advantages inherent in the use of an established concern for this purpose. The money is then turned over to the organization paymaster and timekeeper for distribution.

### ACTIVITY OF RELIEF COMMITTEE

The relief committee supplies direct and indirect relief in all forms, together with the developing and prosecution of plans for "made work." The working of this committee perhaps may be presented most easily by considering the procedure of an engineer presenting himself for assistance. He first goes to the committee on registration where he fills out duplicate cards, one of which goes to the registrar who determines his engineering status and decides whether or not it entitles him to relief from the committee; the other card is filed with the committee on research and vital statistics. Cross-reference of these latter cards is made to show the applicant's so-called "degree of destitution" as follows:

**Table I—Dollar Value Obtained by Feb. 15, 1932**

| | |
|---|---|
| Cash collected | $ 68,928.98 |
| Unpaid pledges | 14,488.63 |
| Contributed for administration | 5,318.91 |
| State and federal contributions to carry on work of the U.S. Geological Survey | 24,000.00 |
| Relief obtained by P.E.C.U. men through others (wages, etc.) | 99,025.00 |
| Certain relief funds for use in portions of United States not covered by P.E.C.U | 5,683.35 |
| Total | $217,444.87 |

1. If in need of immediate aid
2. If his resources will last one month
3. If his resources will last for longer periods

The engineer is next interviewed by the department of employment which endeavors to place him immediately in some gainful occupation, always giving preference to those in immediate need. If a member of one of the four societies, he is also automatically registered with the Engineering Societies Employment Service for a permanent position.

If the interview with the registration committee indicates that the engineer requires immediate financial help or legal advice, he is sent to the department of certification of loans and payroll where, if deemed advisable, he is given a requisition on the treasurer for a loan, in return for which he gives his note which is non-interest bearing and payable on demand. Clothing, if necessary, is made available by the social service committee sponsored by the Engineering Woman's Club. Sound advice or legal assistance is made available without expense by the legal counsel.

Arrangements have been made with Columbia University whereby unemployed professional engineers are admitted to lecture courses on engineering and allied subjects without fee and without academic credit. In this way they not only may improve their general mental attitude, but may place themselves in a position to increase their earning capacity at the end of the economic depression.

There is a committee on plans, the function of which is to survey and chart the possibilities for "made work," having an allied committee charged with the responsibility of putting these plans into effect. A committee on opportunities in business and industry was started the first of the year to make contact with various business and industrial organizations, bringing to their attention the possibility of having their plants surveyed by unemployed engineers so as to improve plant layout and processes of manufacture, and increase efficiency.

WORK ACCOMPLISHED

Direct contact is maintained between the P.E.C.U. and the Engineering Societies Employment Service to provide permanent positions, when available, for the registrants. These two bodies, however, are entirely separate, the P.E.C.U. being motivated to provide prompt relief for engineers in immediate need and register all engineers out of work. It is financed entirely by voluntary gifts.

On February 15, 1932, the total registration had reached 1,900, somewhat less than half of which consisted of members of the four engineering societies. Of those registered on that date, immediate help had been found to be needed by [illegible]. A total of 446 already had been placed in positions. Contact is maintained with registrants and the records revised from time to time. As shown by Table I the total dollar benefit obtained by the P.E.C.U. for the engineering profession was $217,441.87.

In addition to the direct financial benefit, there are of course many other advantages being derived from this plan, and it is intended to support actively the various forms of unemployment relief so long as the emergency exists. Plans are now being made for a more direct canvass of professional engineers who are in a position to contribute. The registration continues to increase each week, and as many of these are cases of destitution, the committee is spurred to greater activity.

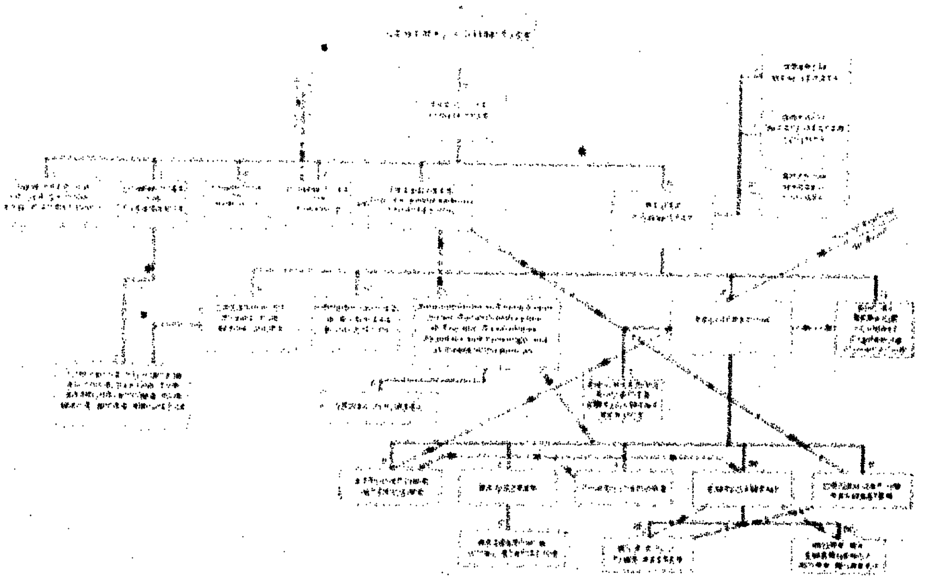
ENGINEERS' NATIONAL RELIEF FUND

Based upon a contribution of $5,000 received from President Hoover, a fund for national use is being built up, administered by a separate committee composed of F. C. Hutchinson, Chairman, W. G. Atwood, Langdon [illegible], and E. B. Meyer, representing, respectively, the mechanical, civil, mining and electrical engineering societies, and with Ernst Hartford, assistant secretary of the American Society of Mechanical Engineers, acting as secretary of the committee. The policy has been adopted for the use of the fund as a loan primarily for members of the four national societies, or to members of local societies with which the local sections of the four societies are affiliated. The loans will be the basis of a revolving fund, and will be made only for brief periods consistent with providing an emergency service.

Because of the limited size of the fund, it is felt that so far as possible the engineers in the larger communities where sections of the societies are organized should care for their own engineering dependents, so that some latitude will be provided for aiding the very considerable number of engineers living in isolated parts of the country where there is no organized group to take interest in them.

AMERICAN ENGINEERING COUNCIL PLAN

The American Engineering Council also is active in unemployment relief, working through state councils and local committees. While assisting in relieving the immediate unemployment situation, the more important phases of the work being carried on by this body probably are those concerned with the permanent stabilization of employment and industry, and in urging local, state, and national governments to adopt measures which may relieve the present situation and be effective in preventing recurrences of the present cycle. A recent report of this body includes the prediction that a marked social advance will result from the present widespread relief activity; better relations between employers and employees are being built up, a sober view of public financing is being taken, and corporate management is being shaped along sounder lines. It is asserted that these and other constructive developments arising from the depression will make for a more stable economic organization.



Organization chart of the New York City Professional Engineer's Committee on Unemployment

## Sectional Committee on Noise Recommended

The organization of a sectional committee on noise measurement under the procedure of the American Standards Association was recommended by a general conference of 32 representatives of 18 national bodies held in New York, N. Y. on January 29, 1932. It also was recommended that this committee function under the technical leadership of the Acoustical Society of America. The scope of the project as recommended by a steering committee, consisting of Prof. V. O. Knudsen, E. E. Free, P. L. Alger (F'30), H. R. Summerhayes (M'16), R. G. McCurdy (M'28) and Dr. Harvey Fletcher (F'30), is the preparation of general standards of nomenclature, units, scales, and measurement in the field of acoustics, with special reference to noise measurements.

It was the feeling of the Institute's committee on sound under the chairmanship of P. L. Alger that the widespread interest in noise and the rapid development now going on in noise measuring instruments make desirable national standards in this field. Already there are eight or more national noise committees, most of which have definitely set before themselves the task of preparing standards of noise measurements. Hopeless confusion must result unless these various projects are coordinated by some such means as this recently organized sectional committee under the A.S.A. Therefore the A.I.E.E. committee on sound cordially endorses the formation of this sectional committee and expresses its desire to carry out its work on noise standards through this organization. It is the further feeling of the Institute's committee that the scope of the sectional committee should be as stated by that body, namely, the preparation of general standards of noise measurements, and that test procedure and standardized methods of defining the noise characteristics of particular apparatus in particular locations should be left to the individual member organizations for later development.

The concentration of the sectional committee's work for the present chiefly on the standardization of nomenclature, units, and scales should become the basis for further progress in the science of noise measurement. The complex nature of noises and their effects upon the ear introduce confusion in the measurement of noise, and none of the noise meters yet designed can translate the approximate physiological and psychological effects of noise into definite units of measurement. Definition and standardization of these factors alone will do much to make possible real progress in the engineering application of our knowledge to the reduction in noise of apparatus.

# Letters to the Editor

## The Reactive Voltampere Conventions

*To the Editor:*

When we say that the "power factor" is leading we mean by tacit agreement that the current leads the voltage. Further, when we plot these as vectors, we are required to use a counterclockwise rotation to agree with mathematical custom.

Now if leading reactive voltamperes are called negative, there is a reversion in appearance to the old clockwise diagrams, leading voltamperes appearing to lag behind the power unless a clockwise sense is assumed. If power and reactive voltamperes are considered as true double-frequency vectors then we are forced to define leading reactive voltamperes as positive in order to maintain the counterclockwise convention. In this I am assuming that the polarities of mathematics must be accepted in all Cartesian charts.

To argue that lagging reactive voltamperes should be positive because $R + jX$ represents an inductive impedance is useless, for the inverted argument that it should be called negative because $G - jB$ represents an inductive admittance is just as good and more to the point in constant voltage systems.

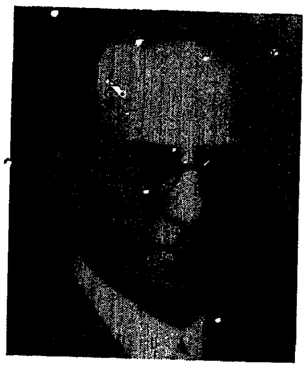
Be consistent, call leading reactive voltamperes positive and maintain the appearance of counterclockwise rotation.

Very truly yours,

V. G. SMITH (A'26)
(Assistant Professor of Electrical Engineering, University of Toronto, Toronto, Canada)

[**Editor's Note:** This letter discusses one division of the "Proposed Definitions of Power System Terms" (see ELECTRICAL ENGINEERING for February 1932, p. 106-7) developed by a special subject committee of the A.I.E.E. committee on power transmission and distribution. Further discussion is invited on any of the proposed definitions.]

# Utility Executive Advanced



F. B. LEWIS

F. B. Lewis, formerly vice-president and assistant general manager of the Southern California Edison Company, Ltd., Los Angeles, has been promoted to the position of vice-president and general manager. Mr. Lewis graduated from Rose Polytechnic Institute at Terre Haute, Ind., 26 years ago, and has been with the Edison Company continuously since that time. Among his early accomplishments was the installation of the first 33-kv. transmission line by the Edison company to bring power from Santa Ana River Canyon to Los Angeles, Calif.

# Engineering Foundation

## Election of United Engineering Trustees Held

Officers elected to serve United Engineering Trustees, Inc. for the year 1932 have been announced. H. A. Kidder (F'29) was elected president, and H. V. Coes and Col. A. S. Dwight were named vice-presidents. Dr. A. D. Flinn, director of the Engineering Foundation, will serve as secretary, and C. P. Hunt as treasurer. Other members of the board of trustees were chosen as follows: F. E. Winsor, Boston, Mass.; C. A. Mead, Newark, N. J.; A. S. Tuttle, New York, N. Y.; G. D. Barron, Rye, N. Y.; R. M. Roosevelt, New York, N. Y.; E. R. Fish, Hartford, Conn.; F. A. Schaff, New York, N. Y.; H. P. Charlesworth (F'28), New York, N. Y.; and A. W. Berresford (F'14) New York, N. Y.

The United Engineering Trustees was established in 1904 as the United Engineering Society "to advance the engineering arts and sciences in all their branches, to further research in science and engineering, to maintain a free public engineering library, and to advance in any other manner the profession of engineering and the good of mankind." As the joint agency of the four national societies representing the civil, mining, mechanical, and electrical engineers, it owns and administers the Engineering Societies Building at 33 West 39th Street, certain endowment and other funds, and other properties committed to it. Through the Engineering Foundation, the library board, and the administrative department, it aids research in engineering and the sciences, operates the Engineering Societies Library, and carries on other activities.

# Standards

## Standards Committee Meets During Winter Convention

At the meeting of the standards committee of January 26, 1932, a number of subjects was discussed. Attention was called to a difference between A.I.E.E. standard No. 20, "Air Circuit Breakers," and the standard of the National Electrical Manufacturers Association for the same apparatus. The A.I.E.E. rule permits a 30-deg. cent. rise on contacts whereas N.E.M.A. permits only 20 deg. After receiving the report of the A.I.E.E. subcommittee which developed "Air Circuit Breakers" the standards committee approved a change in the A.I.E.E. Standard to 20 deg. unless objection is registered by the principal users of air circuit breakers.

At this same meeting, the recommendation of the standards council of the A.S.A. that the sponsorship for the sectional committee on wires and cables, now vested in nine associations including the A.I.E.E., be transferred to the sole sponsorship of the electrical standards committee was recommended to the board of directors for approval. This newly-organized electrical standards committee (as described on p. 845 of ELECTRICAL ENGINEERING for Oct. 1931) is the joint body representing eleven organizations and working under the A.S.A.

A suggestion of the scopes committee

of the electrical standards committee that the title of A.I.E.E. pamphlet No. 100 "Recommendations for the Operation of Transformers" be changed to "Recommended Practise in the Temperature Operation of Transformers" was presented to the standards committee and approved. No. 100 now will go to letter ballot of the standards council of the A.S.A. for approval as American recommended practise. Also, in accordance with a suggestion of F. D. Newbury (F'21) the standards committee on January 26 recommended an extension of scope of the sectional committee on transformers to cover all transformers and other equipment contained in A.I.E.E. standards No. 12 "Constant-Current Transformers," No. 13 "Transformers, Induction Regulators and Reactors," No. 14 "Instrument Transformers" and also pamphlet No. 100 "Recommendations for the Operation of Transformers."

The committee recommended to the board of directors the approval by the Institute as a joint sponsor of the reports of the sectional committee on radio dealing with "Standard Vacuum Tube Base and Socket Dimensions" and "Manufacturing Standards Applying to Broadcast Receivers."

A report made up of definitions relating to telemetering has been received from the instruments and measurements committee. As the sectional committee on electrical definitions has a subcommittee under Dr. J. F. Meyer (M'13) dealing with instruments and testing, the report of the technical committee was referred to that group for consideration and inclusion in their report.

## Form and Arrangement of Published Standards

The report of the special committee on form and arrangement of published standards was made under date of November 30, 1931 and now is available in pamphlet form. This report is the work of a special committee of the American Standards Association, appointed in January 1925. The committee's objective has been the preparation of publication practises to be recommended by the A.S.A. for use by all bodies developing standards particularly under A.S.A. procedure.

The committee selected a page size of 7¾x10⅝ in. but also recognized three other suitable sizes. Alternative procedures are included in a number of other instances. It is hoped that experience in using the recommended practises will permit eventual elimination of the alternatives. Copies of the report may be obtained from A.S.A. headquarters, 29 West 39th Street, New York, N. Y.

# Personal

J. C. Parker (A'04, F'12) who has been chosen to succeed M. S. Sloan to the presidency of the Brooklyn Edison Company, Brooklyn, N.Y., has been its vice-president in charge of engineering since 1926. Besides being possessed of a wide experience in the many practical fields of application of the profession he has had considerable experience also in the academic field. For some time he was an instructor in mechanical and electrical engineering at Union College, Schenectady, N. Y., under Dr. C. P. Steinmetz, giving in addition a course in thermodynamics and another in the mathematics department. His B.S. in M.E. was conferred upon him by the University of Michigan from which he was graduated in 1901, this same institution the next year conferring upon him his A.M. degree for advanced work in mathematics, physics, and structural engineering. In 1904, his E.E. degree was won also from the University of Michigan by work done *in absentia*. Returning to the industrial field in 1904 Mr. Parker became assistant to the engineer in charge of construction and design for the Ontario Power Company's plant at Niagara Falls, the largest hydroelectric undertaking of its time. Upon completion of the first section of the Ontario Power Company's plant in 1905, he went to Buffalo as assistant to the vice-president and chief engineer of the construction company building the lines of the Niagara, Lockport, and Ontario Power Company from Niagara Falls to Syracuse. This was the first 60,000-volt transmission line, and the engineering for it was done by R. D. Mershon (A'95, F'12) past-president of the Institute. In this same year Mr. Parker became mechanical and electrical engineer of the Rochester Railway & Light Company, in charge of the engineering department; to this engineering work shortly was added the organizing of the power sales engineering division and economic investigation of power and illuminating conditions in company works. In 1915 the University of Michigan recalled him as professor of electrical engineering in charge of its department of electrical engineering, and this was the position from which he resigned in 1922 to become electrical engineer of the Brooklyn Edison Company. While primarily interested in higher mathematics and physics, Mr. Parker later became deeply concerned with the practical aspects of standardization and the simplification of production, design and construction. He was chairman of the Institute's delegation to the American Standards Association, and December 9, 1931, at the annual meeting of the American Standards Association was elected to serve (1932) as vice-chairman of the Standards Council. He has served the Institute in several capacities including that of vice-president (1921-2). He is a member of the American Society of Civil Engineers, the American Society of Mechanical Engineers, and of the Engineers' Club of New York.

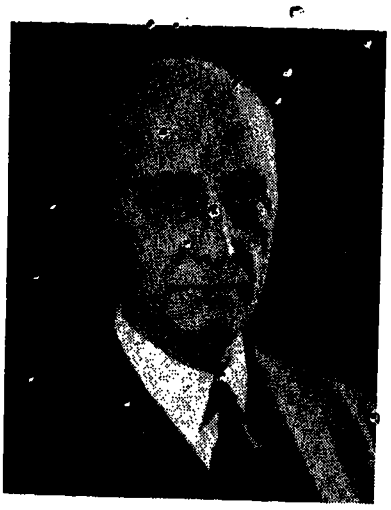
J. C. PARKER

Giuseppe Faccioli (A'04, F'12) who retired from active professional service May 27, 1930, when he withdrew from the office of works engineer and associate manager of the Pittsfield works of the General Electric Company, has been chosen as the A.I.E.E. Lamme medalist for 1931. Mr. Faccioli, a native of Italy, graduated with high honors in both mechanical and electrical engineering from the Institute of Technology at Milan. He came to this country at the age of 25 and spent the first year of his career upon the design of a-c. machinery. He attracted the attention of the late William Stanley, inventor of the transformer, and through this association and that with other pioneer engineers, Mr. Faccioli has accomplished professional work which forever will be outstanding in the electrical engineering world. High tribute has already been paid him by men prominent in the profession; he has been hailed

GIUSEPPE FACCIOLI

as "a mathematical genius and a veritable wizard" in his chosen calling, but as "none the less human" in consequence of this personal achievement. Especially have the younger engineers gained from him knowledge and inspiration. His work with the General Electric Company covered a span of 25 years, and upon his retirement he was presented with a testimonial, brilliantly hand illuminated and signed by more than 150 names of the men who had worked with and for him during that period of his own service to the company and to the profession. This presentation was made in Schenectady, N. Y., by the late Doctor L. T. Robinson, (A'04, F'12), then in charge of the company's general engineering laboratory, with S. H. Blake (A'03, F'17), general engineer of the General Electric Company, and J. L. R. Hayden, the other member of the company's general standardizing committee. Always keenly interested in the A.I.E.E., Mr. Faccioli has been an untiring worker in its behalf, serving on many of its committees and as manager and vice-president. In 1928 he was decorated by Mussolini with the emblem of the Commandant of the Crown of Italy. Mr. Faccioli in relinquishing active duties with the General Electric Company becomes a consulting engineer, retaining his keen interest in all affairs of the organization.

PHILIP TORCHIO



F. W. SMITH

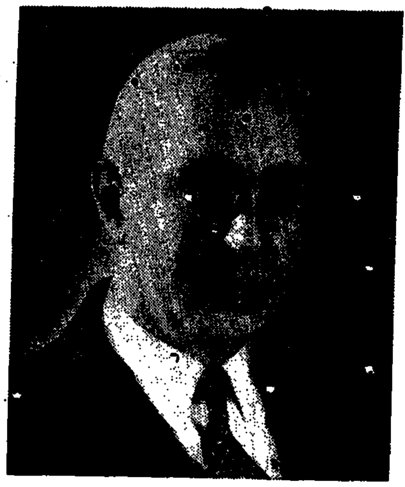
W. D. COOLIDGE

Philip Torchio (A'95, F'12) vice-president of the New York Edison Company, New York, and past-president of the New York Electrical Society, has been elected by his board of directors to serve as senior vice-president of the New York Edison Company. Mr. Torchio was born in Como, Italy, in 1868 and came to New York in 1893. He became a naturalized citizen and since 1895 has been with the New York Edison Company interests. He served for many years as a consulting engineer for affiliations of the Consolidated Gas Company and the New York Edison: namely, United Electric Light and Power Company, New York and Queens Electric Light and Power Company, Yonkers Electric Light and Power Company, the Westchester Lighting Company, and the Bronx Gas and Electric Company. He pioneered in the introduction of the 132,000-volt underground cable in this country and is the author of considerable technical literature on the economics of electric light and power generation and distribution. He is a member of Franklin Institute, has served the Institute as chairman on committees on power transmission and distribution, power stations, and economics of electric service, and as a member of the standards committee, the United States National committee of the International Electrotechnical Commission, electrical machinery committee, meetings and papers, power test code, and protective devices committees. In the Association of Edison Illuminating Companies, he has acted as chairman of the committee on high potential disturbances, symposium on system troubles, committee of conferees on armature coil temperatures of large generators and the committee on high tension cables. Also he has been a member of the committee on power generation and the committee on standards, and a representative on sectional committee on ratings of the American Engineering Standards Committee, now the American Standards Association. He was chairman of the National Electric Light Association's committee on underground construction and of the joint conference committee on standards. Mr. Torchio was a member of the American committee on electrolysis, the American Commission to the World Power Conference, American Engineering Standards committee sectional committee on rating of electrical machinery and the sectional committee on insulated wires and cables.

F. W. Smith (A'05, M'12) who has been serving the United Light and Power Company of New York as its vice-president and general manager, has been chosen to succeed M. S. Sloan as president of the New York Edison Company and the United Electric Light and Power Company. Already Mr. Smith is chairman of the board of directors of the New York and Queens Electric Light and Power Company and president of the Brush Electric Illuminating Company of New York. The year 1930 rounded out an uninterrupted 52-year service with the United Electric Light and Power Company, which he joined as a thirteen-year-old office boy in 1880 when the company was known as the United States Illuminating Company. This was two years prior to the opening of the Pearl Street station of the Edison Company and three months after the perfection of the incandescent lamp by Thomas A. Edison. In 1889 he was appointed paymaster for his company which then had become the United Electric Light and Power Company; 1891 found him assistant auditor, and eight years later he was elected to the office of assistant secretary. A year later he became secretary of the Brush Electric Illuminating Company, of which he in 1929 became president and a director. Of the United Electric Light and Power Company he was made secretary in 1905, vice-president in 1912 and general manager in 1916. In 1926 Mr. Smith was elected chairman of the board of the New York and Queens Electric Light and Power Company; in February a year ago he was made vice-president of the New York Edison Company. He has been active also in the affairs of the National Electric Light Association for many years, of which he was elected vice-president in 1919 and president in 1922. Under his presidency the association expanded considerably, Mr. Smith being largely instrumental for the formation and organization of its geographic sections. He has been chairman of many of the association's committees, and an active member of a large number of others; for sixteen years he has served as chairman of its lamp committee and is still a member of the public policy committee. In its early days he was actively connected with the Electric Vehicle Association and in 1923 was its president. This was shortly before the association became a part of N.E.L.A. activities. In addition to several other technical organizations, Mr. Smith is a member of the Electrical Association of New York, the New York Electrical Society and the Engineers' Club. In his long and assiduous service in the electrical profession he has commanded confidence as a conservative, open-minded administrator, giving particular attention to all complaints which came to him, and the maintenance of cordial public relations.

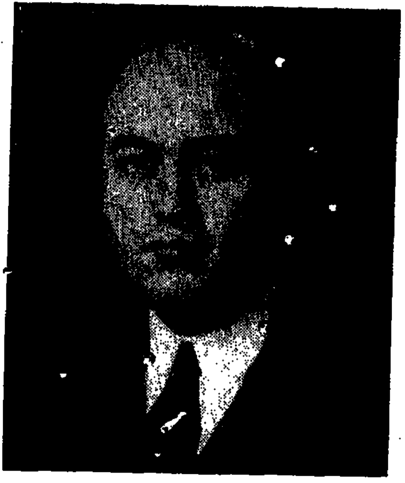
W. D. Coolidge (A'10) associate director of the research laboratory of the General Electric Company, Schenectady, N. Y., on February 24, 1932 received the Washington Award for his "scientific spirit and achievement in developing duc-

H. A. KIDDER



B. F. Kutcher Studio

KERN DODGE



A. H. KEHOE

tile tungsten and the modern X-ray tube." A native of Hudson, New York, Doctor Coolidge was graduated from Massachusetts Institute of Technology in 1896, at that time receiving his B.S. degree; in 1899, he won his Ph.D. from the University of Leipzig. At M.I.T. he has been assistant in physics, instructor in physico-chemistry and assistant professor in physico-chemical research. In 1905 he associated himself with the General Electric Company and ever since 1908, when he was made assistant director has been in the research laboratory. In 1914 he received the Rumford Medal for his invention and application of the ductile tungsten. This medal is awarded bi-annually by both the Royal Society and the American Association of Arts and Sciences, "for the most important discovery and useful improvement" during the two years immediately preceding the date of award. He has also been the recipient of the Franklin Institute's Howard N. Potts Medal (1926) "in consideration of the originality and ingenuity shown in the development of a vacuum tube that has simplified and revolutionized the production of X-rays," and the Louis Edward Levy Gold Medal, another Franklin Institute award for professional achievement. In 1927 he received the gold medal of the American College of Radiology and the Hughes Medal of the Royal Society, London. Doctor Coolidge enjoys extensive membership in the scientific and technical groups, among them being the American Chemical Society, the American Electrochemical Society, the American Physical Society, the American Academy of Arts and Sciences, and the Washington Academy of Sciences. Also he is an honorary member of the American Roentgen Ray Society, the American Radium Society, the Radiological Society of North America, the Roentgen Society (of England), Societe de Radiologie Medicale (of France), and Nordick Forening for Medicinsk Radiologi.

**H. A. Kidder**, (A'06, F'29) superintendent of motive power, Interborough Rapid Transit, New York, has been elected president for 1932 of the United Engineering Trustees, Inc., joint agency of the four national engineering societies, 29 West Thirty-Ninth Street, New York, N. Y. His appointment as electrical superintendent of the Interborough Rapid Transit came in 1914, following his employment in the railway motor department of the General Electric Company; six years later he was advanced to assistant superintendent of motive power, his further advance to superintendent coming in 1921. Mr. Kidder has served the Institute in a multiplicity of committee connections including power generation, power stations, headquarters, standards, special committee on Institute prizes, the engineering profession, special committee on technical activities, executive, finance, coordination of Institute activities, Edison Medal, transportation, U.S. National committee of International Electrotechnical Commission, and meetings and papers (now technical program committee) and still is active as Institute representative to the United Engineering Trustees, American Engineering Council, on the A.I.E.E. board of examiners, law, and legislation. For three years he was on the board of directors, served one year as chairman of the Institute's New York Section, and for two years as a vice-president. He is a past-president of the New York Electrical Society, and a member of the American Electric Railway Association. At present Mr. Kidder is devoting a great deal of his time to the Professional Engineers' Committee on Unemployment, on which he is serving as chairman of the finance committee.

**Kern Dodge** (A'02, M'12) consulting engineer and aviation enthusiast of Philadelphia, Pa., who recently received appointment as director of public safety of the City of Philadelphia, is a native of Chicago, and was graduated from Drexel Institute in 1907. For four years, before and after school of each day, he took charge of the electric plant at the works of the Link-Belt Company, where finally in complete charge of new electrical equipment, he changed over the entire system to electric drive. He was placed in charge of the electrical equipment at the Harrison Safety Boiler Works of Philadelphia, where he later entered into a partnership with Charles Day (now of Day and Zimmerman) in a consulting engineering practise. This company subsequently became Dodge, Day and Zimmerman, and Mr. Dodge's work was chiefly in connection with public utility properties, his earlier consulting work having been the design, layout, and construction of power plants, transmission lines and substations. A registered professional engineer in the State of Pennsylvania, Mr. Dodge now is a director of the Link-Belt Company, a member of the New York Electrical Society, the American Society of Mechanical Engineers, and the Illuminating Engineering Society. He is said to be an expert in the field of aviation, and the first engineer in the history of Philadelphia to be appointed director of public safety. This also is the first political appointment Mr. Dodge has had.

**A. H. Kehoe** (A'12, F'25) electrical engineer of the United Electric Light and Power Company was one of those chosen vice-president of the New York Edison Company at a recent meeting of its board of directors. As superintendent of transmission and distribution and for over nine years electrical engineer of the United Electric Light and Power Company, as well as a member of several important subcommittees of the electrical apparatus committee of the National Electric Light Association, Mr. Kehoe has established for himself a reputation of capability. His estimable record with the United Electric Light and Power Company started in 1911, in the laboratory on special investigations and design of new equipment. He progressed to important work in the meter department, and thence to the engineering department, where his duties were in connection with substation design and construction, also distribution system engineering in the arrangement of cable systems and service, transformers on network systems and the location and elimination of faults, and the maintenance of the continuity of service. He also worked on transmission system design and protection. He has contributed to technical literature, setting forth interesting and instructive phases of his own valuable experience. In his endorsements to the grade of Fellow was the commentary "his engineering work is admirable and his ethical standards of the highest."

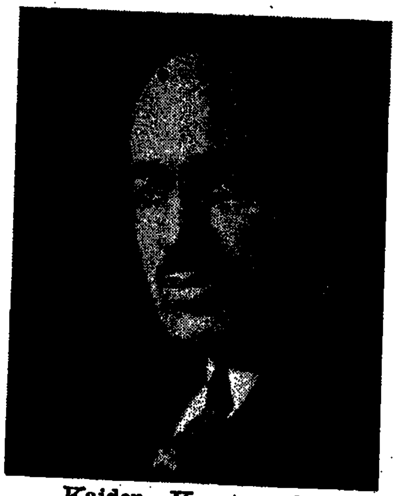
**M. S. Sloan** (A'07, F'30) for the past number of years identified as president, trustee and director of the several companies of the Consolidated Gas Company system, at a recent meeting of the board of directors tendered his resignation. Mr. Sloan's professional career includes a rapid rise from humble beginnings with small southern power companies to early service with the General Electric Company and assistant to the president of the power company at Birmingham, Ala. Thence he went to New Orleans in 1917, returning from that point to become assistant to the president of the New York Edison Company, and finally succeeding Nicholas F. Brady (A'01) as president of the latter company.

R. H. TAPSCOTT (A'18, F'29) who has just been elected a vice-president of the New York Edison Company, became electrical engineer of the Edison company in 1925. His first appointment to office there, following his resignation from the General Electric Company, took place in October 1917, when he was made assistant chief electrical engineer. Mr. Tapscott's activity in committee work, both in the Institute and other societies, has been well known. In the A.I.E.E., he has served as a member of the executive committee of the standards committee for a number of years, on the electrical machinery committee one year, on the power transmission and distribution committee two years, and as chairman of the headquarters committee since 1928; in 1930 he completed a term as chairman of the New York Section. Besides, he has been chairman of the electrical apparatus committee of the National Electric Light Association, a member of its engineering national committee, and as a member of the electrical advisory committee is at present representing the light and power group. Mr. Tapscott has at all times evidenced not only high engineering ability, but a fine sense of professional ideals.

S. N. BOSE (A'13, M'22) who since 1926 has been assistant, and later, deputy chief electrical engineer of the Tata Iron and Steel Company, Ltd., Jamshedpur, India, now is chief electrical engineer of that organization. Notice in the December issue of ELECTRICAL ENGINEERING implied that Mr. Bose had gone to India only recently; the above therefore serves as a correction to the earlier statement. Mr. Bose's New York connection immediately prior to his going to India in 1926 was with the J. G. White Engineering Corporation, his affiliation with the Cazenovia Electric Company, Cazenovia, N. Y., having preceded that with J. G. White.

FREDERICK KRUG (A'17, M'25) vice-president and general manager of the Porto Rico Railway, Light and Power Company, San Juan, has been elected president of the Chamber of Commerce of Porto Rico, affiliated with the Chamber of Commerce of the United States. Mr. Krug is president also of Porto Rico Service, Incorporated, a business man's organization which promotes new industries on the island and exhibitions on the mainland. He is an able member of the governor's insular employment relief committee and of other organizations for civic welfare.

A. W. LEE (A'08) who has been serving the Louisville Gas and Electric Company in the capacity of general superintendent, now has become vice-president in charge of operation to succeed LEWIS STARR STRENG (A'04, F'26) recently deceased. In addition to his new duties as vice-president, Mr. Lee's name has been added to the directorate of the Louisville company. He also has been very active in the field of aviation, and was chairman of a special committee appointed by former Governor Sampson to draft the present state aviation laws.



Kaiden—Keystone Studios

R. H. TAPSCOTT

SANNOSUKE INADA (A'22) one of the most distinguished of Japanese engineers, and one who since 1925 has served as director general of telegraph and telephone engineering of the Teishinsho, or department of communication of Japan, retired on January 11, 1932. He is well known in both American and European communication circles, and his work with the Teishinsho began in 1900 when he was graduated from the College of Tokio Imperial University. Since 1925 he has been also a professor of Waseda University.

HENRY SNYDER (A'24) recently elected president of the New York and Queens Electric Light and Power Company, New York, N. Y., has been interested in the public utilities of Queens ever since 1899 when he assisted in merging two Newtown and two Flushing companies into the New York and Queens Gas and Electric Company. He was president of the New York and Queens Gas Company, resigning to devote all his attention to the development of the electric company, of which he became vice-president several years ago.

SIR OLIVER LODGE, scientist, has been made the recipient of the Faraday Medal presented by the council of the Institution of Electrical Engineers, of Great Britain. He is 80 years old. Sir Oliver's experiments with high frequency oscillations led to the discovery and invention in 1894 of the coherer which contributed to the advancement of wireless telegraphy. The Faraday Medal is awarded not more than once a year for notable scientific or industrial achievement in electrical engineering.

T. S. BURNS (A'31) has been made senior engineer, United States Engineers Office, Huntington, W. Va. Mr. Burns in 1930 was senior hydroelectric engineer, U.S. War Department, in charge of preparation of power report for the Pittsburgh district, and prior to that was estimating engineer with the Pennsylvania Water and Power Company, Baltimore, Md., in charge of estimates on the Safe Harbor project, Susquehanna River.

B. S. BESSESEN (M'27) an associate electrical engineer in the United States Civil Service, who has been acting superintendent of the Muscle Shoals Development, Ala., for the past year, now has received his appointment as superintendent. Mr. Bessesen has held responsible positions in power development projects in the west and from 1922 to 1924 was instructor in electrical engineering at Oregon State College, Corvallis, Ore.

E. S. FITZ (A'16) manager of production and transmission for the past year or so, for the Virginia Electric and Power Company, Richmond, Va., recently was appointed general manager of the electric department for the entire system which serves tidewater Virginia and northeastern North Carolina. His new position gives him charge of distribution as well, and he will continue to make Richmond headquarters.

E. V. SAYLES (A'23, M'30) who has been investigations engineer for the electrical engineering department of Allied Engineers, Inc., Jackson, Mich., now has become general engineer for the Commonwealth and Southern Corporation, in Jackson. Mr. Sayles has served on the underground systems committee of the N.E.L.A. and is a member of the Association of Iron and Steel Electrical Engineers.

A. H. DICKINSON (A'30) formerly research assistant in the department of fuel and gas engineering, Massachusetts Institute of Technology, Cambridge, Mass., has joined the International Business

Machine Corporation, New York, N. Y., as assistant engineer. While a member of the M.I.T. research staff, Mr. Dickinson developed a method for the more accurate calibration of high pressure gas meters.

H. P. Charlesworth (M'22, F'28) vice-president of the Institute and of the Bell Telephone Laboratories, Incorporated, New York, N. Y., and A. W. Berresford (A'94, F'14) past-president of the Institute and managing director of the National Electrical Manufacturers Association, New York, N. Y., are two of the recently elected board of trustees of United Engineering Trustees, Inc.

Daniel W. Mead (A'11, F'13) consulting engineer, New York, N. Y., and Madison, Wis., and professor of hydraulics and sanitary engineering at the University of Wisconsin, at the annual meeting of the American Society of Civil Engineers, held in New York at the Engineering Societies Building, January 20, 1932, was made an honorary member of that organization.

R. W. Sorensen (A'07, F'19) professor of electrical engineering at the California Institute of Technology, Pasadena, Calif., recently was made a member of the board of consulting engineers for the Metropolitan Water District of Southern California. The February issue of Electrical Engineering incorrectly referred to this appointment as one to the board of directors.

J. A. Cook (A'15, F'30) superintendent of the electrical department of the Lynn Gas & Electric Company, Swampscott, Mass., recently was elected chairman of the New England System Operators' Club, and S. C. Jacoby (A'21) superintendent of transmission and distribution, of the Montaup Electric Company, Fall River, Mass., was chosen as the club's secretary.

A. E. Kennelly (A'88, F'13) past-president of the Institute and professor emeritus of electrical engineering, Harvard University and Massachusetts Institute of Technology, Cambridge, Mass., recently was elected an honorary member of the German Elektrotechnischer Verein, and also of the Japanese Institute of Electrical Engineers.

R. M. Garth (A'24) who was distribution engineer for the Knoxville Power and Light Company and associated companies, the Tennessee Public Service Company and Holston River Electric Company, now has been made assistant electrical engineer, Navy Department, Bureau of Yards and Docks, Washington, D. C.

L. S. Horner (A'04) formerly president of Niles-Bement-Pond and Kissel Kinnicutt and Company, New York, N. Y., now has removed to Bridgeport, Connecticut, as vice-president of the Bullard Company. During 1930-31, Mr. Horner was a director of the United States Chamber of Commerce.

L. M. Klauber (F'23) heretofore vice-president and general superintendent of the San Diego Consolidated Gas and Electric Company a subsidiary of the Byllesby Engineering and Management Corporation of Chicago has been chosen vice-president in charge of operation for the San Diego company.

Mabel MacFerran (A'28) who has been technical assistant to the operating engineer of the Southern California Edison Company, Los Angeles, Calif., now has been made assistant electrical engineer of the Metropolitan Water District of Southern California, Los Angeles, Calif.

G. C. WARD

W. J. Miller (A'19, M'26) resigned as dean of engineering and professor of electrical engineering at Texas Technological College to accept the position of professor and head of the department of electrical engineering at the University of North Carolina, effective January 1932.

C. O. Von Dannenberg (A'06, M'30) previously serving the Electric Management and Engineering Corporation, New York, N. Y., as assistant electrical engineer, now has joined the engineering department of the Pennsylvania Central Light and Power Company, Altoona, Pa.

C. G. Jones (A'16, M'18) has left the Westinghouse Electric and Manufacturing Company's head offices at East Pittsburgh, Pa., and his work as inductive heating engineer, to become special engineer for the Youngstown Sheet and Tube Company, Youngstown, Ohio.

E. W. Morris (A'29) has been transferred to the Westinghouse Electric and Manufacturing Company's San Francisco office in the capacity of industrial application engineer. Previously Mr. Morris was with the company's Los Angeles office as general engineer.

C. L. Farrar (A'23) who has been serving as associate professor of electrical engineering, University of Arkansas, Fayetteville, Ark., now is engaged in the electrical engineering department of the school of electrical engineering, University of Oklahoma, Norman, Okla.

C. N. Brubaker (A'19, M'29) in the past managing engineer of the transformer department, General Electric Company, Erie, Pa., has added his name to the roll of the Institute's Pittsfield Section as a result of his recent transfer to the company's Pittsfield office.

F. J. Stevens (A'12, M'27) who has been serving as superintendent of the Parkersburg (W. Va.) plant of the Porcelain Products, Incorporated, recently identified himself with the American Lava Company, Chattanooga, Tenn., as production engineer.

R. B. Tenney, Jr. (A'10) recently joined the Power Cost Engineering and Appraisal Corporation of San Antonio, Tex., as its consulting engineer in Dallas. His previous affiliation was as engineer of the Texas Power and Light Company, also at Dallas.

Alexander Nyman (A'19, M'26) who heretofore has served the Radio Patents Corporation, New York, N. Y., as vice-president, resigned from that position and now is consulting engineer for the Shortwave and Television Corporation, Boston, Mass.

W. C. Woodson (A'22) formerly assistant engineer, meter department of the New York Edison Company, now is assistant engineer in the meter and test department of the United Electric Light and Power Company, Irving Place, New York, N. Y.

E. D. Wood (A'21, M'26) formerly electrical operating engineer for the Louisville Gas and Electric Company, now has been advanced to the office of general superintendent, to succeed A. W. Lee (A'08) who has assumed new executive duties.

F. D. Spofford (A'23) previously traffic engineer for the Wheeling Traction Company, (W. Va.) has been selected assistant to the president of the Blue Ridge Lines, the bus subsidiary of the West Penn Electric Company of Pittsburgh, Pa.

G. C. Ward (M'24) was recently elevated to the rank of senior vice-president of the Southern California Edison Company, Ltd., Los Angeles, Calif., as announced in Electrical Engineering for February 1932, p. 140.

R. J. Clingerman (A'29) has resigned from his work with the Consolidated Gas Electric Light and Power Company of Baltimore, Md., and made new connections in the sales department of the Ochiltree Electric Company at Pittsburgh, Pa.

R. M. Arnold (A'25) who was chief engineer of the radio division of the United Air Cleaner Company, Chicago, Ill., recently was elected vice-president and chief engineer of the United Air Cleaner Corporation of Chicago.

E. F. Venn (A'28) formerly inspector of the maintenance engineering department of the Western Electric Company, Kearny, N. J., has gone to Clewiston, Fla., as assistant engineer for the United States Sugar Corporation.

G. H. Bucher (M'24) assistant general manager of the Westinghouse Electric International Company, New York, N. Y. recently was elected its vice-president and general manager. His headquarters still will be in New York City.

A. L. Woodhouse (A'02) vice-president of the Dixie Power Company, Cedar City, Utah, has removed to Palo Alto and is now vice-president and manager of the Central Mendocino County Power Company, Willits, Calif.

Erland Johnson (A'25) who has been mechanical and electrical engineer for the Detroit Rock Salt Company, Detroit, Mich., now has engaged as superintendent of the Avery Salt Company, Avery Island, La.

W. H. Spencer (A'27) who as assistant secretary to Montreal Light Heat and Power Consolidated has been supervising accident prevention work for this company, now will specialize in safety engineering.

A. J. Duncan (A'09) previously president and general manager for the Fort Worth Power and Light Company, Fort Worth, Texas, has been chosen president of the Texas Electric Service Company of that city.

Melvin Block (A'30) who has been sales engineer of the Wagner Electric Corporation, at Pittsburgh, Pa., now has joined the American Shoe Machinery and Tool Company, St. Louis, Mo., as a salesman.

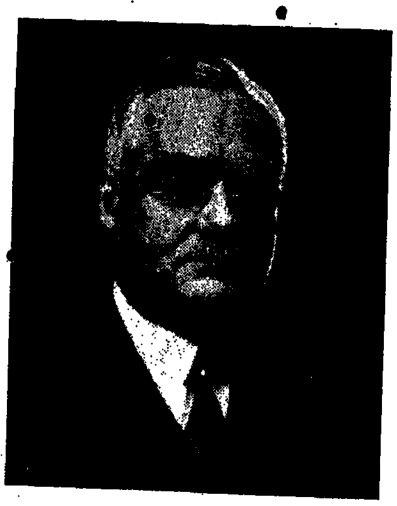
David Nemetz (A'28) who was sales engineer for Electrical Distributors, Vancouver, B. C., Can., recently was made president of the Standard Electric and Radio Company of Vancouver.

M. K. Lock (A'25) who has been serving the firm of Lock, Lang & Austin, Irvington, N. J., as radio engineer, now is chief engineer at the WNJ radio station of Newark, New Jersey.

P. I. Doty (A'30) previously of the industrial department, General Electric Company, Schenectady, N. Y., has been transferred to the company's San Francisco office.

## Obituary

Harold Babbitt Smith (A'91, F'13) junior past-president of the Institute and for 35 years head of the electrical engineering department of Worcester Polytechnic Institute, died February 9, 1932, after an extended illness of almost a year's duration. Doctor Smith was born at Barre, Massachusetts, May 23, 1869. Graduated from Cornell University with the degree of M.E. in E.E. in June 1891; he remained as graduate student until December 1891. In January 1892 he was appointed professor of electrical engineering in charge of the department at the University of Arkansas. Resigning this position later the same year, he became head designer and electrical engineer for the Elektron Manufacturing Company, Springfield, Mass. From September 1893 to June 1896 he was director of the department of electrical engineering at Purdue University. He had held his position as professor of electrical engineering and director of the department at Worcester Polytechnic Institute ever since 1896.



H. B. SMITH

Until 1902 Doctor Smith retained a connection with the Elektron Manufacturing Company as consulting engineer doing consulting work for several other organizations at various times. Since 1905 he had served as a consulting engineer for the Westinghouse Electric and Manufacturing Company of East Pittsburgh, Pa.

In 1904 he was chairman of the international group, jury of awards in electrical engineering at the St. Louis Exposition. During the years 1917-19, he was an associate member of the Naval Consulting Board and consultant of the special board of the Navy on anti-submarine work. He has been a pioneer in the development of high-voltage power transmission systems and equipment, carrying on many researches involving advanced conceptions of dielectric phenomena and stress distribution. He has obtained numerous patents, and has contributed many papers to the transactions of the engineering societies and other technical publications.

Doctor Smith resigned his educational chair at Worcester Polytechnic Institute effective June 1931. As one well known in engineering and education he always has carried forth a multiplicity of duties in these fields. His share in Institute activities has been abundantly represented by service on several of its committees simultaneously, including: law 1920-21; electrophysics and student branches 1920-27; instruments and measurements 1921-22; educational 1922-27; sections 1922-28; Edison Medal 1924-26, 1929-30, 1930-32; research, coordination of Institute activities, and meetings and papers 1924-27; code of principles for professional conduct 1928-29; executive 1929-31; and public policy 1930-31. He was appointed also to the John Fritz Medal board of award for 1929-33, the U.S. national committee of the I.E.C., the Chas. A. Coffin Fellowship and Research Fund committee 1929-30, and the American Engineering Council 1930-31. His other memberships included American Society of Mechanical Engineers (Member), Institution of Electrical Engineers (Great Britain), Society for the Promotion of Engineering Education, American Association for the Advancement of Science, Sigma Xi, and Tau Beta Pi. In 1929 Doctor Smith had two honorary degrees conferred upon him; Doctor of Engineering from Purdue University and Worcester Polytechnic Institute.

Max Toltz (M'22) since 1907 a prominent consulting engineer with offices in St. Paul, Minn., died at his home there January 11, 1932. Mr. Toltz was a native of Koeslin, Germany, where he attended the Koeslin Royal Gymnasium, later winning his civil engineering degree from the Royal Polytechnikum in Berlin, in 1878. A degree of doctor of engineering was conferred upon him in 1924 by the Ramsey Institute of Technology, St. Paul, Minn. After graduation from the Royal Polytechnikum, he served a short apprentice with a Berlin firm and before coming to the United States in 1882 was connected with the Prussian government. In 1889 he became a naturalized American citizen, and devoted the first 25 years spent in the United States to the development of railroads, especially in the northwest. The St. Paul, Minneapolis and Manitoba (later the Great Northern) railway benefited by Mr. Toltz' efforts and energy, his final office with it being engineer in charge of motive power, a position achieved by step-by-step promotions from the position of draftsman. He was consultant in mechanical engineering for the Winnipeg workshops of the Canadian Pacific Railway and also for the Jersey City workshops of the Erie railroad; he was vice-president and general manager for the Manistee and Grand Rapids railroad. During the period 1907-10 the electrification of the Great Northern, the Northern Pacific, Butte, Anaconda & Pacific, and Chicago, Milwaukee & St. Paul railroads deeply engrossed him, as did also work on the ore docks for the Great Northern, Northern Pacific & Soo lines. In 1910 he organized the Toltz Engineering Company of St. Paul, of which he was president, an office which he held also in the successor company, Toltz, King & Day, Inc., formed in 1918. Mr. Toltz retired from active business in 1928. During the World War, from a captaincy which he had held for many years in the Minnesota National Guard, he was given the rank of major in the construction division of the Quartermaster Corps, and in this capacity supervised the construction of General Hospital No. 2, at Fort McHenry, in the city of Baltimore, Md. He was a valued member of the St. Paul Interprofessional Institute, a director of its national board; a vice-president of the American Society of Civil Engineers, a member of the American Railway Master Mechanics Association and of the American Society of Military Engineers. He has served as president of both the Engineering Society of St. Paul and of the Federation of Architectural and Engineering Societies of Minnesota. He was also a member of the Vereines Deutscher Ingenieure. Of the American Society of Mechanical Engineers, which he has served in various capacities since 1904, he has been manager, vice-president, and organizer and first chairman of its St. Paul local section, a member of its executive committee, the 1932 nominating committee, and its committee of awards. The press reports that student loan funds of $15,000 each have been left by Mr. Toltz to the civil and electrical engineering professions, the income from these amounts to be administered by the parent organizations. In 1925 a similar fund was established by him for the mechanical engineers.

Joens Elias Fries (A'04, F'15) chief engineer of the Tennessee Coal, Iron and Railroad Company, Birmingham, Ala., died January 23, 1932, after a prolonged illness. He was a native of Sweden, and was educated there, being graduated from the College of Upsala in 1894 and from the Royal Technical Academy in Stockholm in 1898, with degrees in civil and electrical engineering. In 1900 he engaged with a Stockholm firm manufacturing telephone apparatus; then with the General Swedish Electric Company as estimator for plants of every kind. Following this experience he was appointed superintendent of the Holmia Electric Company of Stockholm, in which capacity he remained until 1903. The next uear he came to America and joined the New York Edison Company, remaining with it briefly before identifying himself with Westinghouse, Church, Kerr and Company for drafting work in connection with the construction of the Long Island railroad electrification. Through the period 1905-07 he was commercial engineer for Allis Chalmers Company, then left for the Canadian General Electric Company, where he became engineer of power plants and power transmission. In 1908 he joined the Crocker-Wheeler Company, spending a year and a half in charge of the estimating department, a like period as industrial engineer, two years as Pacific Coast engineer and the rest of his stay with that company as assistant chief engineer. September 1916 he became chief electrical engineer for the Tennessee Coal, Iron and Railroad Company, a subsidiary of the U.S. Steel Corporation, remaining with these interests up to the time of his death. He was a member of the Association of Iron and Steel Electrical Engineers, the American Society of Mechanical Engineers, the American Association for the Advancement of Science and the American Society for Steel Testing. He also had been a member of the Engineers Club of New York since 1909, and of the Engineers Club of San Francisco since its inception. Mr. Fries was 56 years old at the time of his death.

William Dutton Pomeroy (A'99, M'21) general manager, vice-president and director of the Goulds Pumps, Inc., Seneca Falls, N. Y., died January 6, 1932, after an illness of a year's duration. He had been with the Goulds company since 1908, when he became its general superintendent. His birthplace was Utica, N. Y. (1874). After graduation from Cornell University in 1896, with an M.E. degree, he spent a year as draftsman of the Bossert Electric Construction Company at Utica, leaving it to continue in electrical construction work with the Belt Line Street Railroad Company of that city. He then removed to Akron, Ohio and joined the Akron Electric Manufacturing Company as a draftsman, to be advanced a year later to the office of superintendent and engineer. In this position he remained until 1901, when he was made assistant chief draftsman for the Bullock Electric Manufacturing Company of Cincinnati, Ohio, becoming general superintendent in 1903 and remaining such until 1907. The last year of this period he was also superintendent of the electrical department of the Allis Chalmers Company, Milwaukee, Wis. This was the position from which he went to the Goulds Manufacturing Company, as its general superintendent. Besides his Institute affiliations, Mr. Pomeroy belonged also to the American Society of Mechanical Engineers and the American Institute of Mining and Metallurgical Engineers. By the former he was awarded the Melville Medal for a paper which he prepared jointly with Prof. Herman Diedrichs of Cornell University on the subject of "The Occurrence and Elimination of Surges or Oscillating Pressures in Discharge Lines from Reciprocating Pumps."

Alexander Jay Wurts (A'92, M'92) electrical engineer and a member of the first faculty of Carnegie Institute of Technology, died at his home in Pittsburgh, Pa., January 21, 1932, in the 71st year of his age. His birthplace was Carbondale, Pa. He attended Yale University which in 1883 conferred his Ph.D. upon him. The following year he received his M.E. degree at Stevens Institute of Technology. He then spent two years in the Polytechnikum, Hanover, Germany, and in the fall of 1886 began work with the United States Electric Lighting Company. December of the same year he was placed in charge of the factory of the Julien Electric Company, Camden, N. J., and a year later joined the Westinghouse interests. For eleven years Mr. Wurts was research engineer for George Westinghouse in the development of the Nernst lamp, arresters, etc. His identification with the Westinghouse Electric and Manufacturing Company carried over a period of twenty years; in the course of events he met Andrew Carnegie, and through this acquaintance was elected as the first faculty member of the Carnegie Technical School, which later became known as the Carnegie Institute of Technology. After four years as professor of engineering research, Mr. Wurts gave up teaching, retaining however the chairmanship of the student welfare service of Carnegie Institute. Through the Franklin Institute, Mr. Wurts received the John Scott Medal from the city of Philadelphia for his work with lightning arresters and his discovery of five non-arcing metals. He was a member of the American Philological Society.

**John Robertson Cowley** (A'25, M'29) city electrical engineer, City of Saskatoon, Canada, and past-chairman of the Institute's Saskatchewan Section, died January 16, 1932. He was born in Dundee, Scotland, September 11, 1882, and his early education was obtained at the Harris Academy, in Dundee. His technical training came through two years electrical and mechanical engineering course at the Hariot-Watt College, Edinburgh, and the University of Edinburgh, Scotland. He then served a three-year apprenticeship with an electrical engineering firm in Dundee before joining the Corporation Electricity Works, City of Perth, Scotland. From 1904 to 1907 he was assistant engineer with a municipal tramways company of Scotland, afterwards becoming engineer in charge of distribution for the Clyde Valley Electrical Power Company, Glasgow, Scotland. In 1911 he came to Canada as chief operator for the Canadian Light and Power Company, Montreal. This led to his work with the City of Saskatoon, first as assistant city electrical engineer and then as city electrical engineer, with full charge of generation, distribution, and accounting in the department. His assistantship covered a period of rapid expansion and the results which he obtained through his own leadership were most noteworthy. The city installation included a 10,000-kw. plant and distributing system, in connection with which practically all design and construction devolved upon Mr. Cowley during his term of office, which extended well over a full period of twelve years.

**William H. Fernholz** (M'21) sales engineer of the Electrical Engineer's Equipment Company, at Milwaukee, Wis., died January 25, 1932. He was born in Westphalia, Germany in 1883 and after a full four-year course at a college of engineering in Germany, following earlier training at a technical school in Thuringia, Germany, he came to the United States in 1906 and entered the switchboard department of the Bullock Works, Cincinnati, Ohio. From this first position he changed two years later to drafting work with the Vilter Manufacturing Company, the Johnson Service Company and the Allis-Chalmers Company, respectively, all of Milwaukee; in 1817 he was advanced to the position of chief draftsman of the Federal Rubber Company of Milwaukee, and later in that same year, he became district manager for sales and engineering of the Electrical Equipment Company of Chicago with offices in Milwaukee. While with the Allis-Chalmers Company, Mr. Fernholz did considerable design work in the building of switchboards; also consulting engineering and layout work. He did a valuable amount of important engineering in conjunction with electric power plants, in charge of high-voltage line layout and installations and special design and on construction of switchboards for industrial processes, as well as for the Chinese government. He had been a member of the Institute's Milwaukee Section for some time, and as such took active part in Institute operations.

**William Harrison Bullock** (A'16) for a number of years general engineer of the Westinghouse Electric and Manufacturing Company, Denver, Colo. and past-chairman of the Institute's Denver Section, died January 21, 1932, in his fiftieth year. Mr. Bullock was a graduate of the University of Colorado from which he obtained his B.S. in E.E. in 1904. At the time of his death he was associated with H. S. Sands, consulting engineer in Denver. His service with the Westinghouse company dated from an apprenticeship in 1904, from which time he progressed consecutively through the sales and engineering department to industrial motor application in coal and metal mining and miscellaneous shop applications; also the application of electrical apparatus to agricultural situations to be found in the Rocky Mountain region. Mr. Bullock held membership also in the Electrical League of Colorado.

**Bradley Lyon Child** (A'23) connected with the long lines engineering department of the American Telephone and Telegraph Company, New York, N. Y., as transmission engineer, died January 20, 1932, after a brief illness. He had served this company for 27 years. Born at Meriden, Connecticut, in 1884, Mr. Child came to Brooklyn, N. Y., graduating from Brooklyn Polytechnic Institute with the 1903 class in steam and machine design, and continuing with a special course which he followed by further study on electrical subjects. Since coming to New York, he has always been a resident of Brooklyn. Immediately following his technical studies, he joined the American Telephone and Telegraph Company in New York.

# Local Meetings

## Future Section Meetings

**Akron**

March 8—Electrical Refrigeration and Air Conditioning, by W. M. Timmerman, Gen. Elec. Refrig. Co. Movies. Meeting to be held at Ohio Pwr. Co., Canton, preceded by dinner at Elks Club.

April 12—The Electrical Industry and Some Problems of the Institute, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Movies.

**Baltimore**

March 18—Subject to be announced. Speaker: Capt. Greenlee, Director of Naval Experimental Station.

April 15—Subject to be announced. Speakers from Western Elec. Co.

**Chicago**

March 17—Coordination of Insulation, by F. E. Andrews, Pub. Serv. Co. of Northern Illinois.

**Cleveland**

March 24—Joint meeting with Case Sch. of Applied Science Branch. Speaker: Dr. Dayton C. Miller.

April 21—Electric Refrigeration and Domestic Air Conditioning, by W. M. Timmerman, Gen. Elec. Co.

**Dallas**

March 21—Underground Construction and Cable Developments, by John Oram, Dallas Pwr. & Lt. Co. Meeting to be held in Fort Worth, Texas.

**Detroit-Ann Arbor**

March 15—Vacuum Tubes and Their Application, by E. H. Vedder, Westinghouse Elec. & Mfg. Co.

April 19—Commercial Metering of Electric Energy, by A. S. Albright, Detroit Edison Co.

**Lehigh Valley**

March 18—Research—Industry's Health Insurance, by S. M. Kintner, Westinghouse Elec. & Mfg. Co.

**Louisville**

March 18—Men Who Have Made Electrical Engineering History. Meeting under the auspices of students at Univ. of Louisville. Demonstrations.

April 15—Inspection trip to Bowman Field Airport. Fundamentals of Plane Construction and Flight, by A. W. Lee, Louisville Gas & Elec. Co.

**Lynn**

March 9—Miracles in Nature, by Dr. Pillsbury.

March 16—Local convention. Subject: Recent Developments in the Thomson Research Laboratory, Gen. Elec. Co.

March 26—Inspection trip.

**Pittsburgh**

March 8—Joint meeting with Association of Iron & Steel Elec. Engrs., and Engineers' Soc. of Western Penn.

April 12—Television. Demonstrations. Joint meeting with I.R.E.

**Pittsfield**

March 15—Competitive meeting with Schenectady Section.

**Seattle**

March—Annual joint meeting of Founder societies.

April 19—Joint meeting with Student Branch at Univ. of Washington.

**Spokane**

March 25—Joint meeting with Student Branches at State Col. of Washington and Univ. of Idaho. Papers by local members and students.

April 22—New Developments in Oil Circuit Breakers, by J. F. Spease, Gen. Elec. Co.

**Toledo**

March 18—Inspection trip through Bldgs. 6 and 7 of the Rossford plant of the Libbey-Owens Ford Co.

April 15—Problems in the Design of Large Turbo-Alternators, by S. H. Mortensen, Allis Chalmers Co.; Application of Electricity in Industry, by R. E. Paxton, Toledo Edison Co.

**Vancouver**

March 7—Students' night.

April 4—Switchgear, by W. D. Robertson, Canadian Gen. Elec. Co., Ltd.

# Past Section Meetings

**Akron**

Television, by Dr. J. O. Perrine, Amer. Tel. & Tel. Co. Illus. Dec. 8. Att. 1,600.

X-Ray Inspection of Welds, by Ancel St. John, St. John X-Ray Serv. Corp. Jan. 12. Att. 45.

**Atlanta**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Joint meeting with A.S.M.E. Sec. Jan. 6. Att. 160.

**Baltimore**

Electrons at Work and at Play, by Dr. Phillips Thomas, Westinghouse Elec. & Mfg. Co. Demonstrations. Dinner. Jan. 15. Att. 975.

**Boston**

Photoelectric Cells, by A. R. Olpin, Bell Tel. Labs. Inc. Demonstrations. Moving pictures describing the life of Thomas A. Edison. Jan. 12. Att. 220.

**Chicago**

The Control of Vibration and Noise in Power Stations, by P. E. Stevens, Byllesby Engg. & Mgmt. Corp. Demonstrations. Joint meeting with the Western Soc. of Engrs. Jan. 7. Att. 150.

**Cincinnati**

Industrial Applications of Photoelectric Cells, by E. H. Vedder, Westinghouse Elec. & Mfg. Co. Illus. Dinner. Dec. 10. Att. 110.

Talking Movies—Historical and Present Day Developments, by F. L. Hunt, Bell Tel. Labs. Inc. Illus. Jan. 14. Att. 330.

**Cleveland**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Jan. 21. Att. 126.

**Connecticut**

Vacuum Tubes and Some of Their Applications, by J. D. LeVan, Ratheon Co., F. G. Kelly, Engg. and Research Corp., and H. Raymond, Stanley Works. Demonstrations. Jan. 19. Att. 142.

**Dallas**

Joint meeting with Southern Methodist Univ. Branch. Following papers presented by students: Thyratron Tubes, by J. V. Melton; Deion Circuit Breaker, by J. W. Emery; Recent Developments in Radio Receiving Tubes, by J. N. Walker and D. Ramsey. Jan. 18. Att. 60.

**Denver**

Four Films—"Earl Carroll in the House of Magic," "Mica Insulation by Machine Methods," "Mazda Lamps Preferred," and "The Electric Ship." Dinner. Jan. 15. Att. 70.

**Detroit-Ann Arbor**

The Business of Being a Woman, by Miss S. M. Sheridan, Detroit Edison Co. Dinner, dancing, and bridge. Jan. 19. Att. 91.

**Erie**

The Theories of Ether Waves and Radiation, by W. E. Forsythe, Gen. Elec. Co. Illus. Jan. 19. Att. 125.

**Houston**

Joint meeting with Rice Inst. and A. & M. Col. of Texas Branches. First and second prizes awarded to C. K. Beyette, Rice Inst., and C. C. Nash, A. & M. Col., respectively. Jan. 16. Att. 86.

**Indianapolis-Lafayette**

Arc Welded Steel Houses, by R. G. Eaglesfield, Lincoln Elec. Co. Illus. Dinner. Jan. 15. Att. 30.

**Ithaca**

The Present Economic Situation, by Dean Dexter S. Kimball, Cornell Univ. Joint meeting with Cornell Univ. Branch. Dec. 11. Att. 60.

**Los Angeles**

Aerial Map Making, by L. T. Eliel, Fairchild Aerial Surveys, Inc.; Airport Signaling, by Capt. E. Deeds, Commanding Officer, 478th Pursuit Squad. Dinner. Jan. 12. Att. 250.

**Louisville**

Practical Application of Light Sensitive Cells, by E. H. Vedder, Westinghouse Elec. & Mfg. Co. Demonstrated. Jan. 22. Att. 350.

**Lynn**

Mining of Diamonds in Africa, by Dr. Palache. Inspection of the mineral and glass flower exhibits at the Peabody Museum, Harvard Univ. Jan. 16. Att. 150.

Adventures in Science, by E. L. Manning, Gen. Elec. Co. Jan. 8. Att. 850.

Gas Compression and Application of General Electric Compressors, by R. P. Mansfield, Gen. Elec. Co. S. N. F. Hedman described the various types of compressors manufactured by Gen. Elec. Co. Superchargers, by S. A. Moss, Gen. Elec. Co. Jan. 20. Att. 175.

**Madison**

The Industrial Application of Electron Tubes, by L. L. Ludwigsen, Gen. Elec. Co. Discussion. Dinner. Jan. 20. Att. 47.

**Memphis**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Jan. 8. Att. 65.

**Mexico**

B. E. Arias described the electrically operated bridge spanning the Panuco River at Tamos on the lines of the National Ry. of Mexico. Illus. Jan. 19. Att. 40.

**Milwaukee**

What is Best for the Engineer, by E. S. Nethercut, director and secy. Western Soc. of Engrs. Joint meeting with Western Soc. of Engrs. Dinner. Dec. 16. Att. 250.

The Milwaukee Vocational School—Its Scope and Object, by R. L. Cooley, director. Moving pictures. Dinner. Jan. 20. Att. 125.

**Minnesota**

Informal talks by Prof. J. M. Bryant, K. J. Mertz, R. Reinbold, O. Gaarden, E. H. Hagensick, E. J. LeBlond, and A. C. Willard. Inspection trip through the Northern States Pwr. Co. bldg. Refreshments. Jan. 27. Att. 40.

**Niagara Frontier**

Communication in the Aviation Industry, by E. I. Pratt, Western Elec. Co. Illus. Jan. 15. Att. 175.

**Pittsfield**

Capturing Wild Animals, by Frank Buck. Dinner. Dec. 1. Att. 1,375.

Electrical Instruments as an Aid to Aviation, by C. F. Green, Gen. Elec. Co. Dinner. Dec. 15. Att. 220.

Soviet Russia and Eastern Europe, by Wm. C. White. Dinner. Jan. 5. Att. 1,100.

Foreign Power Systems, by Philip Sporn, Amer. Gas & Elec. Co. Illus. Dinner. Jan. 19. Att. 170.

Jungle Gods, by Capt. Carl Von Hoffman. Feb. 2. Att. 1,350.

**Portland**

The Men and the System Behind the Five-Year Plan, by G. W. Freide. Jan. 19. Att. 143.

**Providence**

Synchronous Driven Electric Clocks and System Regulation from Their Use, by H. E. Warren, Warren Telechron Co. Demonstrations. Jan. 12. Att. 50.

**St. Louis**

A New Type of Silent Fan, by Prof. W. L. Upson, Washington Univ. Demonstrations. Jan. 20. Att. 114.

**San Antonio**

The Eagle Pass Hydro Plant, by G. L. Dowell, Central Pwr. & Lt. Co. Jan. 18. Att. 32.

**San Francisco**

New and Interesting Developments in the Electrical Field, by A. W. Copley, Westinghouse Elec. & Mfg. Co., and W. C. Smith, Gen. Elec. Co. Illus. Michael Faraday, by Wm. Hudgins, student, Univ. of Calif. Dinner. Jan. 22. Att. 112.

**Sharon**

A Beam of Light, by J. M. Kelch, Gen. Elec. Co. Jan. 19. Att. 220.

**Southern Virginia**

Business meeting. Election of officers as follows: Cecil Gray, chairman; E. L. Lockwood, Secy.-Treas.; L. W. Webb and W. R. McCann, members, exec. committee. Electrical Pioneering in Brazil, by W. R. Worth. Dinner. Jan. 21. Att. 10.

**Spokane**

Teletypewriters—The Modern Method of Communication, by R. J. Morgan, Pacific Tel. & Tel. Co., assisted by W. M. Allen, Home Tel. & Tel. Co. Jan. 22. Att. 91.

**Springfield**

Thyratrons, by R. H. Rogers, Gen. Elec. Co. Illus. Nov. 9. Att. 80.

Adventures in Science, by E. L. Manning, Gen. Elec. Co. Demonstrated. Joint meeting with Engg. Soc. of Western Mass. and A.S.M.E. Sec. Dec. 11. Att. 3,000.

**Toledo**

Maintenance of Electrical Equipment, by W. E. Drager, Bunting Brass & Bronze Co.; Safety from the Inspector's Viewpoint, by Frank Lucas; Trolley Coaches or Buses, by

R. H. Dalgleish, Jr., Westinghouse Elec. & Mfg. Co. Moving pictures describing trolley coaches in Chicago and Salt Lake City. Jan. 15. Att. 75.

Lt. Alford J. Williams, Jr., aviation engr., spoke on the present situation in the Far East and the part played by aircraft. Feb. 4. Att. 700.

**Toronto**

Proposed Legislation for Licensing of Engineers, by H. Hellmuth, Assn. of Prof. Engrs. of Ontario. Jan. 22. Att. 104.

**Utah**

Microphones, by Prof. O. C. Haycock, Univ. of Utah; Symon's Crusher Installation at Garfield, by V. J. Del Duke; Unusual Meter Installations, by F. O. Weld, both of the Utah Pwr. & Lt. Co. Jan. 11. Att. 37.

**Vancouver**

National and International Aspects of the Gold Standard, by Prof. H. F. Angus, Univ. of British Columbia. Joint meeting with Engg. Inst. of Canada. Jan. 4. Att. 75.

Magnetic Phenomena in a Two-Phase Static Balancer, by Prof. E. G. Cullwick, Univ. of British Columbia. Feb. 1. Att. 30.

**Washington**

Engineering Aspects of Marine Transportation, by F. V. Smith, Gen. Elec. Co. Dinner. Jan. 12. Att. 85.

**Worcester**

Industrial Lighting, by Alfred Paulus, Westinghouse Lamp Co. Jan. 7. Att. 35.

## Past Branch Meetings

**University of Akron**

Biography of Charles P. Steinmetz, by R. A. Ries, student; Modern Electric Elevators, by P. S. Bechtol, student. Jan. 13. Att. 11.

**University of Arizona**

Film—"The Conowingo Project." Jan. 8. Att. 42.

Electric Furnace, by J. W. Newman, student; Lightning, by T. S. Henderson, student. Jan. 15. Att. 6.

**University of Arkansas**

Construction and Use, Quality and Advantages of Aluminum Cables for Electrical Purposes, by C. B. Owen, The Aluminum Co. of America. Jan. 14. Att. 27.

Electric Elevators, by W. J. Pruett, student; Electric Furnaces, by R. B. Stone, student. Jan. 20. Att. 23.

**University of British Columbia**

Power Distribution in the British Isles, by C. E. G. Brown, student; Armature Reaction in Tap Wound D. C. Machines, by D. S. Smith, student. Films—"Hydroelectric Power" and "Oil Circuit Breakers." Jan. 11. Att. 19.

Dust Precipitation by Electricity, by J. D. Mitchell, student; Radio Broadcast Control, by W. B. Smith, student; Photoelectric Cells, by H. C. Freedman, student. Jan. 26. Att. 16.

**Bucknell University**

Steam Turbine Generator Sets, by W. E. Hall, student. Dec. 9. Att. 10.

Modernization of Industries, by I. Z. Hertzler, Hertzler & Zook Co. Jan. 13. Att. 36.

**California Institute of Technology**

Carl Hines and J. M. Gaylord, Metropolitan Water District, discussed the construction and electrical features of the Metropolitan aqueduct. Jan. 21. Att. 38.

Film—"New Dollar Liner, President Coolidge." Jan. 29. Att. 130.

**University of California**

The Application of X-Rays to Speech Analysis, by Prof. R. T. Holbrook. Refreshments. Jan. 28. Att. 76.

**Case Sch. of App. Science**

Experimenting with High Frequency Oscillators, by C. L. Harvey, student; A Thesis on the Power Factor of Condensers, by R. W. Schindler, student. Dinner. Jan. 14. Att. 21.

**Catholic University of America**

Electricity—Its History and Growth, by Dr. Valade. Refreshments. Jan. 13. Att. 29.

**University of Cincinnati**

Recent Developments in Electro-Chemistry, by Prof. E. C. Farnau. Refreshments. Jan. 20. Att. 45.

**Clarkson College of Technology**

Inspection trip to the Sugar Island, Hannawa Falls, Brown's Bridge, and Higley plants on the Racquette River. Oct. 26. Att. 27.

Inspection trip through the plant of the Aluminum Co. of America. Nov. 11. Att. 21.

**Clemson Agricultural College**

X-Rays and Their Applications, by H. L. Wyant, student; Electrification of the Airship Akron, by W. F. Tribble, student; Practises Used by the American Cast Iron Pipe Co., by W. M. Thames, student; Inspection of Boilers by X-Rays, by L. C. Black, student. Jan. 28. Att. 15.

**Colorado Agricultural College**

Films—"Life of Edison and Invention of Incandescent Lamp," and "Edison Visits General Electric Mazda Plant and Research Laboratories." Jan. 11. Att. 22.

**University of Colorado**

Discussion. Jan. 13. Att. 33.

The Teletypewriter, by Mr. Carr, Bell Tel. Co. Demonstrated. Jan. 27. Att. 106.

**University of Denver**

Business meeting. Jan. 18. Att. 13.

Film—"The Single Ridge," Feb. 2. Att. 55.

Inspection trip through the Amer. Tel. & Tel. Co. bldg. Feb. 5. Att. 56.

**University of Detroit**

Ultraviolet Radiation, by Mr. Garwood, Gen. Elec. Co. Films—"Vacuum Tube Synchronizing Equipment," and "Hydroelectric Power." Jan. 13. Att. 50.

The Latest Developments in Electricity, by W. A. Furst, Westinghouse Elec. & Mfg. Co. Moving pictures. Feb. 3. Att. 18.

**Drexel Institute**

Experiments on One-Quarter Million Volt Lightning Machine and Cathode Ray Oscillograph, by I. Eldridge, Elec. Serv. & Supply Co. Demonstrations. Jan. 20. Att. 35.

**Duke University**

Stanley Flack, chairman, gave a summary of the activities at the Conference on Student Activities, District No. 4, held at the Univ. of Florida. Jan. 14. Att. 23.

Stanley Flack and Mr. Debrunny, students, gave talks on radio circuits. Feb. 4. Att. 23.

**University of Florida**

Film—"The Single Ridge." Jan. 20. Att. 43.

**Georgia School of Technology**

Talk by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Joint meeting with A.S.M.E. Branch. Jan. 7. Att. 160.

**Harvard University**

Inspection trip to the short-wave and television laboratories, Boston. Jan. 12. Att. 37.

**University of Illinois**

Joint meeting with the Urbana Section. Papers presented by students as follows: The Electron Tube in the Modern World, by F. M. Deerhake; Electrification of Railways in India, by R. D. Varma; Television, by D. L. Pettit; The Thermocouple and Its Application to Temperature Measurements of Electrical Apparatus, by B. Figlewski. Jan. 6. Att. 31.

**Iowa State College**

Three Power Locomotives, by John Cross, student; The Root of Three, by Mr. Proctor, student. Jan. 20. Att. 79.

**University of Iowa**

Michael Faraday, by George Koval, student. Dec. 9. Att. 40.

Military Aviation, by Capt. Hide, U.S. Air Corps. Moving pictures. Dec. 16. Att. 142.

Modern Illumination, by Mr. Cleaver, Westinghouse Lamp Co. Joint meeting with A.S.M.E. Branch. Jan. 6. Att. 100.

**Kansas State College**

Film—"The Busy Body." Talks by four students. Dec. 17. Att. 38. Afternoon meeting. Program repeated same evening. Att. 65.

Television, by Mr. Higgenbottom. Film—"Pillars of Salt." Jan. 7. Att. 62. Program repeated same evening. Att. 40.

**Lafayette College**

Hydrographic Surveying, by A. M. Tomkins, student; Theory of Vacuum Tubes, by W. G. McLean, student. Jan. 21. Att. 21.

**Lehigh University**

Experiences on R-17 Test, by Carl W. Banks, student; Industrial Applications of Electricity, by D. M. Petty, student. Refreshments. Jan. 8. Att. 35.

**Lewis Institute**

Hydraulic Engineering, by G. Pfau, Allis-Chalmers Co. Illus. Jan. 22. Att. 160.

My Summer in Europe, by D. E. Dunne, student. Jan. 28. Att. 85.

**Louisiana State University**

Discussion. Dec. 19. Att. 22.

Economic Problems of Public Utilities, by R. M. Dreyfus, student; Rectification, by G. De La Matyr, student. Jan. 15. Att. 18.

**University of Louisville**

Discussion. Jan. 13. Att. 14.

**University of Maine**

The Business Side of the Public Utility, by R. T. Haskell, Bangor Hydroelectric Co. Jan. 14. Att. 32.

**Marquette University**

Demonstrations of various chemical experiments. Moving pictures. Joint meeting with A.S.M.E., A.S.C.E., and A.S.Ch.E. Branches. Dec. 10. Att. 250.

Discussion. Jan. 7. Att. 20.

**Michigan Col. of Mining and Technology**

The Life of Charles P. Steinmetz, by F. J. Komerska; Electrochemistry, by Prof. C. M. Carson. Jan. 14. Att. 22.

Electricity in Mining Engineering, by Prof. C. H. Baxter. Film—"King of the Rails." Jan. 28. Att. 25.

**Michigan State College**

Discussion. Feb. 2. Att. 16.

**University of Michigan**

Railroad Electrification, by H. L. Andrews, Gen. Elec. Co. Jan. 19. Att. 98.

**School of Engineering of Milwaukee**

The Newer Developments in the Telephone Industry, by George French, Wisconsin Tel. Co. Illus. Jan. 14. Att. 248.

**University of Minnesota**

Electrical Radiation Energy as Applied in Medical Practise, by Paul Luckenback, Gen. Elec. Co. Illus. General Electric Student Shop Course, by F. Suhr. Films—"Automatic Substations," and "Electric Trolley Buses." Jan. 21. Att. 95.

**Missouri School of Mines and Metallurgy**

Short talks by eight students. Jan. 14. Att. 9.

Electrical Construction Practise, by Wm. B. Fisher, Union Elec. Lt. & Pwr. Co. Jan. 27. Att. 40.

**University of Missouri**

Atoms and Electrons, by Dr. H. D. Arnold, Bell Tel. Labs. Inc. Joint meeting with Sigma Xi. Nov. 11. Att. 153.

Principles Governing the Action of the Photoelectric Cell, by N. R. Beers, student; Commercial Uses of the Photoelectric Cell, by De Laporte Johnson, student. Dec. 16. Att. 26.

Prospecting by Radio, by C. L. Lewis and A. E. Coffman, students. Jan. 13. Att. 20.

**University of Montana**

Papers by students: A New Warning Beacon, taken from *Electric Journal*, presented by Lewis Ambrose; Electrical South, by H. Archibald; Frequency Converter Sets Installed Outdoors, taken from *Electrical World*, presented by Harry Beck; Helical Grooves in Slip-Rings and Commutators, taken from Electrical Engineering, presented by E. Blanchard; Water Power Resources of Montana, by Arthur Buckley. Jan. 7. Att. 104.

A Weather Station on Wheels, taken from *Tycos*, presented by Edgar Dolum; The Milwaukee Electrical Shops, taken from *Electric Traction*, presented by Leonard Estey; Communication in the New Waldorf-Astoria, by Edward Fisher; Nerve Injuries from Electric Shocks, taken from Electrical Engineering, by Wesley Funk; Arc Welding Aluminum, by Vern Hankins; Telephone Apparatus for the Hard of Hearing, taken from *Bell Laboratory Record*, presented by Curtis Hanson. Jan. 14. Att. 100.

**University of Nebraska**

What an Engineering Student Should Get Out of a College Course, by Dean O. J. Ferguson. Election of officers: Walter M. Ely, chairman; John Hutchings, vice-chairman; A. L. Coffin, secy.-treas. Dinner. Jan. 13. Att. 35.

Inspection trip through the Northwestern Bell Tel. Co. bldg. Feb. 3. Att. 32.

**Newark College of Engineering**

Magnetic Testing, by Mr. Morningstern, Western Elec. Co.; Oil Filled Cables, by I. Mirkin, student. Jan. 25. Att. 18.

**College of the City of New York**

Election of officers: Robert G. Herzog, chairman; John Ragazzini, secretary; Jean Marcus, vice-chairman; Charles Grossfeld, treas. Jan. 7. Att. 16.

The Electron Tube—A New Tool for the Electrical Engineer, by O. H. Caldwell, editor *Electronics*. Illus. Feb. 11. Att. 84.

**New York University**

A-C. Arc Welding, by L. S. Lindorf, student; Thyratron Tubes, by G. M. Heckel, student. Feb. 9. Att. 13.

**North Carolina State College**

Smoker and discussion of Branch problems. Jan. 12. Att. 42.

**University of North Carolina**

The Field for Electrical Engineers, by Prof. W. J. Miller. Jan. 14. Att. 25.

**North Dakota State College**

Iron Ore Mining, by James Samways, student. Film—"Arteries of Industry." Jan. 27. Att. 40.

**University of North Dakota**

Fifty-Kw. Transmitter of WTIC, by Wm. Denk, student; Speed Torque Curves of Induction Motors, by A. Eynon, student. Jan. 13. Att. 15.

Mercury Arc Rectifiers, by Leland Hauck, student. Luncheon. Jan. 20. Att. 15.

The Mathematical Development of Fourier's Theory, by Prof. H. F. Rice, counselor. Election of officers: A. J. Redmann, chairman; C. R. Moore, vice-chairman; G. I. Anderson, secy.-treas. Feb. 3. Att. 15.

**Northeastern University**

Lightning, by Prof. C. L. Dawes, Harvard Univ. Refreshments. Jan. 13. Att. 112.

**University of Notre Dame**

Mathematics as Taught in German Universities and Secondary Schools, by Prof. P. G. Menge; Illumination, by Joseph Bean, student; The Robot, Our Electrical Superman, by Wm. Fromm, Jr., student; Life and Achievements of Thomas Edison, by John Scanlon, student. Illus. Dec. 14. Att. 52.

Weather and Climate, by Prof. D. Hull; Electrification of Coal Mines, by A. Neal, student; Electrification of Railroads, by A. Hiegel, student. John Scanlon presented the engg. digest. Jan. 18. Att. 62.

**Ohio Northern University**

Various Types of Electric Railways and Costs of Construction, by Donald Highlands, student. Nov. 19. Att. 20.

**Ohio State University**

Non-Technical Aspects in Engineering, by Mr. Bibber. Charles B. Sloan elected chairman. Jan. 14. Att. 28.

**Oklahoma A. & M. College**

Store and Show Window Lighting, by T. Hutchinson, student. Jan. 11. Att. 24.

**University of Oklahoma**

Noise Induction, by E. V. Jennings, Bell Tel. Co. and C. E. Bathe, Okla. Gas & Elec. Co. Jan. 13. Att. 98.

**Oregon State College**

Development and Application of Loading Coils to Telephone Circuits, by E. MacCracken, student; Choosing a Communication System for a Power Co., by J. B. Manning, student. Jan. 18. Att. 42.

Development and Use of the Vacuum Tube Voltmeter, by K. Eldredge, student. W. Hynes, student, described his summer work on the Ariel Dam. Feb. 3. Att. 21.

**Pennsylvania State College**

Grinding of Quartz Crystals for Use in Radio Work, by P. G. Cooper, student. Talk by R. K. McClintock, student. Jan. 13. Att. 29.

**University of Pittsburgh**

Mr. Hays, Westinghouse Elec. & Mfg. Co., described his travels through Central and South America. Dec. 1. Att. 87.

Electrolytic Condensers, by E. S. Drobick, student; Modern Aspects of Rigid Airships, by K. Hartwig, student. Dec. 3. Att. 124.

History of the Telephone and Toll System, by J. A. Cadwallader, Bell Tel. Co. of Pa. Dec. 10. Att. 122.

Discrepancies in Our Electrical Units, by H. E. Evans, student; Nela Park Works, Gen. Elec. Co., by F. E. Sauerburger, student. Jan. 7. Att. 123.

**Pratt Institute**

Constructional Details of Electric Meters, by A. R. Warrell, student; Oscillations in Vacuum Tubes, by H. Harrison, student. Jan. 11. Att. 28.

**Purdue University**

Surge Generators, by T. T. Woodson, student; Radio Broadcasts, by R. R. Brunner, student. Nov. 3. Att. 64.

The Thyratron Tube, by Dr. Nottingham, M.I.T. Nov. 24. Att. 250.

Film—"The Single Ridge." Dec. 8. Att. 33.

**Rhode Island State College**

M. J. Carr, student, gave a résumé of the principal engineering developments during the past year. Jan. 21. Att. 12.

Construction and Purpose of the Poulsen Arc, by Messrs. Porter and Andrews, students; Theory and Application of the Non-Linear Circuit, by Leon Breault, student. Jan. 28. Att. 28.

**Rose Polytechnic Institute**

Oil Electric Locomotives, by J. T. Jones, student; Hydrogen, a Cooling Medium for Large Machines, by C. N. McGillivray, student; Dibutyl Phthalate, by J. Neimi and J. Montgomery, students. Jan. 13. Att. 36.

**University of Santa Clara**

Film—"Rubber." Joint meeting with A.S.M.E. Branch. Jan. 13. Att. 100.

Recent Developments in the Field of Electrical Engineering, by W. C. Smith, Gen. Elec. Co. Joint meeting with A.S.M.E. Branch. Jan. 21. Att. 93.

The Sunnyvale Airbase, by Wendell Thomas. Joint meeting with A.S.M.E. Branch. Jan. 28. Att. 87.

**University of South Carolina**

Business meeting. Jan. 11. Att. 14.

Boulder Dam, by H. G. Smith, student; Construction of Voltage Divider, by J. A. Kaigler, student. Jan. 14. Att. 34.

**South Dakota State School of Mines**

Annual frolic. Jan. 15. Att. 65.

**University of Southern California**

Discussion. Jan. 6. Att. 18.

Business meeting. Jan. 13. Att. 16.

Election of officers: M. C. Marshall, chairman; L. H. Bayha, vice-chairman; R. R. Moore, secy.; M. B. Gentillon, treas. Jan. 20. Att. 18.

**Stevens Institute of Technology**

Future Possibilities of the Diesel Engine, by Prof. E. H. Fezandie. Jan. 15. Att. 46.

**Syracuse University**

Frequency Converters, by O. H. Peters, student; Keokuk Hydroelectric Development, by M. Collins, student. Jan. 8. Att. 21.

Oil Filled Cables, by A. B. Rowley and L. M. Keenan, students. Jan. 15. Att. 21.

Harmonics in Transformers, by H. Francis, student; Automatic Pilot, by Wm. Bangs, student. Jan. 22. Att. 21.

**Texas A. & M. College**

A Study of the Peculiarities of Telephone Rates, by J. W. Bouton, student; Designs of a Vacuum Tube Voltmeter, by C. C. Nash, student; Potential Instrument Transformers, by C. W. Bruns, student; Instrument Current Transformers, by R. L. Suggs, student; Steam Turbines in Power Generation, by O. T. Halliday, student; Auto-Transformers, by J. E. Hurley, student. Jan. 14. Att. 50.

**Texas Technological College**

Gaseous Tube Lighting, by C. T. Hatchett, student; Service and Service Organization of Large Communication Companies, by Evans Riley, student. Jan. 13. Att. 12.

Prof. L. S. Grandy elected counselor for the remainder of the year ending July 31.

**University of Texas**

Radio Airway Beacons, by Prof. R. Cranberry. Election of officers: Herman F. Barsun, chairman; E. Neuenschwander, vice-pres.; Wm. Garrett, secy.-treas.; Lowell Baker, corresponding secy. Jan. 14. Att. 25.

**University of Utah**

Football and Other Athletics in Their Relation to Life, by I. J. Armstrong. Jan. 14. Att. 57.

**University of Vermont**

Prof. L. P. Dickinson, counselor, gave a description of the winter convention of the Institute. Feb. 1. Att. 20.

**Virginia Military Institute**

Tests in the Westinghouse Laboratory, by C. W. Horseman, student; Transportation on Land, Sea, and Air, by W. B. Gibbs, student; The Gain in Flight Safety, by H. L. Woodson, student; Electricity in Modern Medicine, by J. T. Brugh, student. Feb. 9. Att. 52.

**Virginia Polytechnic Institute**

Examination and Certification of Engineers, by E. E. Barnard. Jan. 28. Att. 176.

Electric Drive for Power Plant Auxiliaries, by L. H. Morris, student; The Weather Report Instruments of the Akron, by W. H. Johnson, student. Feb. 4. Att. 42.

**University of Virginia**

Beauharnois Harnesses St. Lawrence for 2,000,000 H.P., by G. K. Carter, student; The Electrical Equipment Installed in the U.S.S. Akron, by R. W. Talley, student. Jan. 22. Att. 13.

**University of Washington**

Telephone Transmission, by J. R. Tolmie, Pacific Tel. & Tel. Co. Illus. Jan. 7. Att. 27.

Television, by T. M. Libby, Pacific Tel. & Tel. Co. Jan. 14. Att. 38.

Film—"Evolution of Power." Jan. 28. Att. 30.

**Worcester Polytechnic Institute**

Discussion. Jan. 25. Att. 25.

**University of Wyoming**

Electric Welding, by F. Wegher, student. Jan. 12. Att. 10.

Modern Telephone Practise, by L. R. Probst, Mountain States Tel. & Tel. Co. Neil H. Sanders, pres.; F. W. Wegher, vice-pres.; E. Cogswell, secy.-treas. Feb. 2. Att. 12.

## Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Araldsen, O., Westinghouse Club, Wilkinsburg, Pa.
Beck, B.O., 6165 Winthrop Ave., Chicago, Ill.
Berry, Wayne J., c/o Genl. Elec. Co., Schenectady, N.Y.
Bugg, Vernon, 736 Transportation Bldg., Washington, D.C.
Fay, John L., Genl. Del., Philadelphia, Pa.
Goldsman, Jacob L., 64 Priory Rd., Hampstead, London, Eng.
Keilien, S., 52 St. Francis St., Medford, Mass.
Kirby, F.M., 369 Lexington Ave., New York, N.Y.
Palit, Hari-Charan, 151 Ganesh Mohal, Benares City, India.
Rogge, C.A., Consumers Pwr. Bldg., Jackson, Mich.
Shapiro, Max, 757 Franklin Ave., Wilkinsburg, Pa.
Thomas, Earl Mead, Intl. Genl. Elec. Co., Schenectady, N.Y.

# Employment Notes

## Of the Engineering Societies Employment Service

## Men Available

### Junior Engineers

E.E. GRAD. 1931, 24, single. 4 yr. experience in machine shop, foundry, and assembly dept. 1 yr. drafting for industrial concern. Desires position with mfg. concern or utility company. Available at once. Location, immaterial. D-311.

DISTRIBUTION ENGR., E.E. Grad. 1931, 20. Mich. State Col., single. 4 months' experience as distribution engr. for utility. Ambitious, hard worker, not afraid of responsibility. Best of references, available at once. D-323.

E.E. GRAD., cooperative college, single, 23, Protestant. Considerable machine shop and construction experience, automotive practise; 2 yr. in G.E. test course, control equip. Seeking opportunity in engg. design and development. Location and salary secondary to opportunity. Available short notice. D-36.

E.E. GRAD. 1931, 22, single, Penn. State Col., available on reasonable notice. 1 yr. experience with silk-mill equipment, 3 months in transmission dept. of utility, 2 semesters motor tests in college. Desires position with utility, engg. or mfg. company. Location, U.S., East preferred. C-9850.

E.E. GRAD. 1928, 25, single. 2½ yr. grad. study. Some experience in geophysical exploration. Available now. Location, immaterial. D-359.

YOUNG ENGR. with exceptional experience, B.S. 1928, M.S. 1930 from Worcester P.I., single, 25. 2 yr. as high voltage research asst. to recent A.I.E.E. pres. 18 months as transformer design engr. for Westinghouse. Will prove valuable to mfr., utility, or construction firm. Location, immaterial. Available now. D-319.

E.E. GRAD. Experience on multiple-unit cars. 18 months G.E. test. Automatic switchboards, motors and generators, power transformers, mercury arc rectifiers. Asst. head of rectifier test. Desires position with pwr., mfg. or ry. company. D-357.

E.E. GRAD., 1929, single, 23. 15 months as student engr. on G.E. test. Some test, drafting, and switchboard construction experience before graduation. Interested in position with a firm doing consulting or construction work or with utility or mfr. Available at once. Location anywhere in U.S., New Eng. preferred. C-8028.

E.E. GRAD., 1931, Clemson Agri. Col., 25, single. Desires work with utility, mfg. concern or construction corporation. Available immediately. Location, immaterial. D-400.

RECENT GRAD., '28, lab. experience including motor and generator design and research, drafting, oscillograph operation, breakdown and iron core-loss tests. Experience in testing industrial control equip. and telephone equip. Available, immediately. C-6611.

E.E. GRAD., 1930, 23, single. 15 months on G.E. test of railway equipment, rectifiers, industrial apparatus, industrial control, and refrigeration development. Desires position with utility or mfg. concern. Available at once. D-409.

E.E. GRAD., 1929, 23, single. M.S. from M.I.T., 1931; 20 months G.E. test course. At present teaching in E.E. dept. of leading tech. col. Desires instructorship in E.E. Available in June. Location, immaterial. C-9462.

E.E. GRAD., 1929, 25, single. M.S. '31 from M.I.T. 1 yr. G.E. test; 4 summers gen. maintenance work with telephone company. Available at once. Will go anywhere, to any position for which qualified. Salary secondary. D-175.

E.E. GRAD., 1930, 25 years of age, G.E. test experience, and about 2 yr. of wiring and repair work. Salary second to a position. Location, immaterial. D-433.

E.E. GRAD., Purdue, 1931, single, 24. 7 months in training course of a large utility company. Experienced in stenographic and secretarial work. Desires position with a future in mfg. concern or utility company. Available at once. Location, immaterial. D-437.

1931 E.E. GRAD., 23, single. High scholastic record (Tau Beta Pi). Type of work and salary secondary. Will go anywhere. Available at once. D-438.

E.E. GRAD., 1931, Worcester P.I., 22, single, member Sigma Xi, desires connection with utility concern, industry, or with teaching, also interested in drafting. Location, immaterial. Available at once. D-228.

E.E. GRAD., 1930, Georgia Tech. cooperative plan. Westinghouse lighting courses. Cooperative work, alternate months, 5 yr. large power company in substation maintenance and office engg. Thorough experience, equip. of utility and industrial customers. Now employed installing and servicing automatic stokers, heat controls, etc. Excellent references. Perfect health. Location, immaterial. C-7847.

E.E. GRAD., 1931, M.I.T. American, 25, single. Desires position with mfg. or utility company. Business environment qualifies him for sales work also. Eastern states preferred, but not essential. Available immediately. D-110.

1931 E.E. GRAD., Lehigh Univ., 23, single. Summer experience in test dept. of utility. Location, immaterial. Available immediately. D-447.

1931 E.E. GRAD., Lehigh Univ., 23, single. 12 months' experience with utility in construction. Ambitious and reliable. Available now for position of any elec. nature. Location, immaterial. D-451.

### Construction

ASSOC. E.E., 34, married, technical education, desires position with utility. Exceptional ability in underground transmission and distribution systems. 1 yr. central station construction experience. Location, immaterial. Available on short notice. D-278.

### Design and Development

ELEC. AND MECH. DESIGN ENGR., 37, married. Pratt Inst. night sch. grad. I.E. course. 12 yr. experience design of generating and substations; industrial layout of factories, warehouses and offices. Practical experience on maintenance of elec. equip. Available at once. C-7979.

PORTABLE TOOL ENGR. 14 yr. experience. Until merger chief engr. second largest company. Expert on universal motor design. Inventive ability combined with exec. and business judgment. D-404.

DESIGNING ENGR., E.E. GRAD., 34, married, 8½ yr. experience in design and selling of high tension outdoor substation, indoor and outdoor switching equip., bus supports and connector fittings. Desires employment with utility or mfg. concern, selling or engg., best references. D-389.

E.E. GRAD., 12 yr. comprehensive experience in designing, drafting and engg. of steam and hydroelectric plants, substations and industrial plants. Conduit plans, wiring diagrams. Available at once. D-411.

M.E. AND E.E. FORMER CORNELL INSTRUCTOR IN MACHINE DESIGN for 4 yr. Allis-Chalmers designer and checker, 5 yr. shop apprenticeship and miscellaneous experience, 32, single. Desires teaching or engg. opportunity. Salary open. D-122.

E.E., 14 yr. in field designing, drafting, testing, patent drafting and layout of elec. lt. and pwr. for bldgs. Available now. C-1095.

E.E. GRAD., 39, single. 11 yr. experience in developing, design and mfg. of small apparatus in the elec. measuring instrument line. Bridges for high and low voltage, pwr. to carrier frequencies. Exceptional theoretical training. Desires connection with high grade firm, eventually as sales engr. where exceptional tech. knowledge required. B-8131.

### Draftsmen

DRAFTSMAN AND INSTRUMENT MAN, 25, single, 2 yr. univ. training, 4 yr. experience on pwr. transmission lines, telephone work, and water resources. Available now. Will go anywhere. C-7118.

ME. E.E. AND C.E. GRAD., Italy, 30. single. Has first American citizenship papers. Desires position anywhere with utility or contractor. 3 yr. varied civil engg., 2 yr. in pwr. production, in steam and hydroelectric plants. Skilled in any layout and topographic work. D-422.

**Executives**

EXEC. MATERIAL. Young man, solid foundation in apprenticeship training, followed by engg. and business training, substantial industrial experience, record of accomplishment, integrity, reliability; creative executive ability, desires opportunity to develop as executive material in progressive mfg. organization. C-8775.

E.E. GRAD., 48. 26 yr. experience as designing, pwr., report and exec. engr., with 3 engg. firms, on industrial and utility properties. Experience covers cost of plants, operating economics, system planning, construction supervision and appraisal of properties for various purposes. B-4553.

E.E. GRAD., Univ. of Wis., 33, single. 3 yr. Westinghouse test. 7 yr. supervising pwr. plant, substation, transmission line construction. 8 yr. engg. inspector purchasing, expediting, writing specifications, resident engr., supervising construction. Excellent reference. Can handle responsibility. Desires connection with holding company, utility or mfr. Available immediately. Location, immaterial. B-9661.

E.E. GRAD., 32, single, additional work M.E., Phi Kappa Phi. 8 yr. broad experience, pwr. house, substation, transmission line, duct system design; estimates, standards, equip. specif., operation. Responsible, capable engr. asst. Desires position with mfr. or in plant mgmt. for util. Salary secondary to opportunity. D-124.

E.E., 44, married. 20 yr. with leading cons. engr., utilities, and mfg. concerns. Experience includes responsibility for design, construction, maintenance and operation of power plants and industrial installations. Competent to supervise elec. design, construction, or maintenance. Perfect health, capable, energetic and adaptable. Available immediately. B-9194.

ANALYST of unusual ability, 44, internationally known, 22 yr. experience applying mathematical and engg. knowledge to analysis of existing records of sales, production, qualities of product, etc., to demonstrate additional sales opportunities. Improvements of mfg. and sales policies and more profits followed analyses. Available short notice. Location, immaterial. D-340.

E.E. seeks position in operating dept. of utility or as industrial plant engr. Married. Tech. grad. Factory test floor experience. 17 yr. varied experience with utility and industrial plants. Speaks Spanish fluently. Location, immaterial. Further information on request. Available on short notice. A-4018.

EXEC. ASST. OR EDITOR, Cornell E.E. Grad. 10 yr. asst. to vice-pres. and gen. mgr. Experienced in engg. writing with leading publications, preparation of bulletins and instruction books. Desires exec. work, writing or sales. A-1558.

E.E. GRAD., 32, single. 9 yr. of design and construction of pwr. trans. lines, substations and distribution networks as engg. inspector, purchasing, expeditor, preparing estimates and writing specifications. Excellent references. Desires connection with holding company, operating company, contractor or mfr. Available immediately. Location, immaterial. C-3564.

ELECTRICIAN OR FOREMAN, 25, single, white. 10 yr. experience in coal and metal mining transportation systems. I.C.S. grad., LaSalle Extension Univ. course in indus. mgmt., now taking E.E. course with American School. Speaks English, Slovanian, Spanish. Worked 3 yr. in S. Amer. Will travel. D-380.

E.E. GRAD., Worcester P.I., 1921, 33, married. 8 yr. experience, engg., design, purchase of equip. and construction of pwr. stations, switching stations and substations, 2 yr. in ry. work. Desires sales engg. work. Location, New York, New Jersey metropolitan preferred. Available immediately. C-9928.

EXECUTIVE, 33, E.E. and M.E. Grad. 12 yr. mfg., production, design, advertising, merchandising, accounting desires position involving major responsibilities. Exceptionally wide contact with all types plants throughout country. Characterized as an able organizer and an alert, untiring worker with vision, a highly practical profit-consciousness and quiet aggressiveness. C-1297.

GRAD. ENGR., 34, married. 12 yr. communication, distribution system construction, materials and construction methods supervising engr., cable installation, etc., for metropolitan and mgmt. utilities. Desires responsible position where practical ability, resourcefulness and good personality is required. D-44.

TRACTION ENGR., 28, single, 5 yr. experience in electric traction shops as inspector, since then and at present in charge of service of southeast on registers. 2 yr. at Georgia Tech., later E.E. grad. from I.C.S. Was radio operator. Desires position as asst. engr. for elec. traction. D-80.

E.E. GRAD. Pwr. station design and elec. distribution experience. Desires position in similar field or in research lab. Temporary position will be considered. Preferred location, metropolitan district of N. Y. or Phila. B-1923.

EXECUTIVE, E.E. GRAD., married, 30 yr. experience, mgr., supt., E.E., construction and operation, utilities. Installed steam—Diesel-hydroelectric plants. Building substations, transmission lines, distributing systems, street car network, laying underground and undersea cables. District mgr., sales representative for mfr. of H.T. oil circuit breakers, switches, transformers. Available now. B-2388.

DIVISION SUPT., 29, married, tech. grad. 5 yr. service utility following positions; division supt., district engr., local mgr., construction foreman. 1 yr. supt., construction, operation municipal pwr., ice plant including distribution. 16 months elec. installation, maintenance, industrial mfg. establishment. 2 yr. lineman, construction, maintenance utility. Available. Location, immaterial. D-442.

E.E., M.E. GRAD., married. 22 yr. experience, designing, construction pwr. plants, substations, transmission, distribution systems, industrial plants. 3 yr. charge purchasing engg. equipment, foreign interests. 3 yr. executive experience charge engg. dept. large utility syndicate. English, German, Russian, Armenian languages. Available immediately. D-84.

**Financial**

FINANCIAL ENGR., E.E.M.E. GRAD., Cornell, experience with regulatory commission, utility holding mgmt. corp., security investing dept. of leading insurance company and financial and fact finding investigation. 4 yr. with outstanding consulting engg. firm. Seeks opportunity in New York City. Salary open. C-2953.

**Instruction**

E.E. GRAD., 26, married, 3 months grad. student Westinghouse E. & M. Co. testing large apparatus, switchboards. 3 yr. teaching drafting large mid-western univ. Will receive M.S. deg. in E.E., business administration in spring. Interested power tubes. Wishes to teach E.E., mathematics, physics, drawing, or industrial position. Available June. D-445.

**Maintenance and Operation**

E.E. GRAD., married, 28, with wide experience in industrial plant elec. construction and maintenance; ry. electrification; pwr. plant design, estimating, and supervisory construction experience with elec. contractor; cost analysis. Desires position with future. C-4428.

E.E. GRAD., 1928, 6 yr. hydro and steam plant elec. operation and maintenance, 5 yr. office and cost accounting. Would desire position with utility or mfg. concern in any part of U.S., or foreign. Salary secondary to opportunity. C-7796.

**Research**

ELECTROACOUSTICS, PHYSICIST, 45, married. 20 yr. experience, industrial laboratories, problems of sound, radio, telephone, dielectric phenomena, etc. Several years' experience consulting engr. these fields. M.I.T., physics, Ph.D. Physics, mathematics, Univ. of Chicago. Open for full or part time consultant, director research, special problems in sound and electroacoustics. D-374.

E.E. GRAD., 1930, 25, single, 1½ yr. experience in statistical and industrial research dept. of prominent civic organization in East. Speaks Spanish fluently. Available now due to organization curtailment. C-7551.

PRODUCT ENGR. Grad. engr. with successful record on improvement of product, machines and methods. Experienced in rolling mill methods, non-ferrous fabricating, steel, rubber, and shipbuilding. Industrial applications of elec. and mech. apparatus. Research and experimental work. Location, immaterial. Salary open. B-6342.

**Sales**

SALES ENGR., Cornell two deg., 6 yr. experience selling wire and cable, specializing with ry. in East. Has service on Pennsylvania, New York Central, Erie and Lackawanna, and wide acquaintance among ry. engrs. B-7881.

SALES ENGR., tech. grad., 38, single. Westinghouse test and shop training. 12 yr. sales experience selling steam and elec. apparatus to central station, transportation and marine industries. Desires position as salesman or application engr. B-4274.

INDUSTRIAL ENGR., 30, married, Wisconsin grad. 2 yr. construction, 2 yr. at Westinghouse, 1 yr. utility valuation, 4 yr. industrial sales development. Broad tech. and commercial knowledge various industries. Desires employment in industrial surveys and reports, industrial sales development, investigations for commercial firm. Location, Middle or South West. C-3082.

CONTROL ENGR., E.E. GRAD., 30, married, 8 yr. experience design, development of automatic and drum type control (under 600 volts) a-c. and d-c. Desires permanent connection engg. or sales department of control manufacture or equivalent. Wisconsin location preferred, but will consider any location. Available immediately. D-443.

SALES ENGR., E.E. GRAD. who has contacted pwr. company engr., purchasing dept., elec. jobbers and contractors for 10 yr. in northern-southern Calif. desires to act as local representative for mfr. Married, age 39. Available at once. Location, San Francisco or Los Angeles territory. D-458-10-C-10-San Francisco.

**Testing**

HIGH TENSION CABLE TESTER, expert experience, large eastern utility, 28, married, E.E. grad., 3 yr. Westinghouse test, mchy., switchgear. 5 yr. utilities, construction testing, d-c. to a-c. changeover, consumers complaints, other contact work. Desires responsible position, utility contemplating organizing or reorganizing elec. testing bureau. Available one month's notice. D-440.

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco
N. D. Cook, Manager

205 West Wacker Drive
Chicago
H. Wierschem, Manager

31 West 39th St.
New York
W. V. Brown, Manager

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

# Membership

## Applications for Election

Applications have been received by the secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the secretary before March 31, 1932.

## Order Form for Pamphlet Copies of A.I.E.E. Papers*

**Milwaukee District meeting papers which are abstracted in this issue**

| Number | Author | Title |
|---|---|---|
| ☐ 32-54 | Edward Bennett | The Proximity Effect and Its Application to the Concentration of Heating Currents in Predetermined Strips |
| ☐ 32-55 | W. C. Lallier | Toll Switching Plan for Wisconsin |
| ☐ 32-56 | C. F. Harding, L. L. Carter and J. W. Olson | Weather Resistant Insulation for Line Wires |
| ☐ 32-57 | E. C. Williams | Electrical Design Features of Waukegan Station |
| ☐ 32-58 | R. B. Williamson | 115,000-Kw. Turbo-Alternator |
| ☐ 32-59 | W. L. Lloyd, Jr. | Insulator Sparkover |
| ☐ 32-60 | A. O. Austin | An Improved Type of Limiting Gap for Protecting Station Apparatus |
| ☐ 32-61 | J. J. Torok and C. G. Archibald | Design and Economic Selection of Suspension Insulator Assemblies |
| ☐ 32-62 | H. A. Frey and K. A. Hawley | Normal Frequency Arcover Values of Insulators |
| ☐ 32-63 | O. K. Marti | The Mercury Arc Rectifier Applied to A-C. Railway Electrification |
| ☐ 32M3 | C. D. Brown and E. W. Hatz | The 60-Cycle Primary Transmission System of the Milwaukee Electric Railway and Light Company |
| ☐ 32M6 | C. Stansbury | A General Method of Gaseous Tube Control |
| ☐ 32M7 | O. M. Ward | Mercury Arc Rectifier versus Rotary Converter Automatic Railway Substations |
| ☐ 32M8 | R. E. Pierce | Police Teletypewriter Communication |
| ☐ 32M9 | J. L. Hecht | Development of the Waukegan Station of the Public Service Company of Northern Illinois |
| ☐ 32M10 | E. X. Schmidt | Electrical Instruments in the Gas Industry |

# Engineering Literature

## New Books

### In the Societies Library

AMONG the new books received at the Engineering Societies Library, New York, during January are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

POWER PLANT MANAGEMENT. W. N. Polakov. N. Y. & Lond., McGraw-Hill Book Co., 1932. 176 p., 8x5 in., cloth, $2.00.——Outlines an efficient and economical method for organizing the human side of power-house work in various factories and power plants, including duties of various employees, methods of accounting and recording, and wages.

THOMAS A. EDISON, Benefactor of Mankind. By F. T. Miller. Chicago, Phila., Toronto, John C. Winston Co., 1931. 320 p., 9x6 in., cloth, $1.50.——A well illustrated popular life of Edison, the first since his death, with the cooperation of the family and associates of Edison. An excellent account.

RECOLLECTIONS OF EDISON. By D. T. Marshall. Boston, Christopher Publishing House, 1931. 117 p., 8x5 in., cloth, $1.75.——Dr. Marshall's contribution to Edisonana, though slight, has some interest. As a boy in Metuchen, he was familiar with the Menlo Park laboratory; in 1887 he became a chemist at the West Orange laboratory. His recollections deal with the appearance of the laboratories at that time, the men who worked in them, and their methods and activities.

SYMPOSIUM ON WELDING. American Society for Testing Materials. Phila., 1931. 151 p., 9x6 in., cloth, $1.75.——Eleven papers presented at a meeting of the society in Pittsburgh, March 1931, with discussions. Includes a general survey of processes, account of processes for welding aluminum, and papers on materials for fusion welding, modern applications of arc welding and recent developments in gas welding. Other papers discuss matters of inspection and testing in the use of the stethoscope, gamma-ray testing, magnetic testing, and fatigue and impact tests.

V D E FACHBERICHTE, 1931. Berlin, V D E—Verlag. 177 p., 12x8 in., paper, 12 RM; bound, 14 RM.——This report contains the technical papers presented at the 1931 convention of the Society of German Electrical Engineers. The theme of the meeting was long distance power transmission, discussing power generation, transmission, interconnection, power utilization, etc. Includes 62 papers.

HANDBOOK OF CHEMISTRY AND PHYSICS. By C.D. Hodgman and N.A. Lange. 16 ed. Cleveland, Ohio, Chemical Rubber Publ. Co., 1931. 1545 p., 7x4 in., cloth, $5.00.——The new edition of this popular handbook contains 180 pages more than the previous one, in addition to extensive revision throughout the book. The book continues to be an exceedingly useful reference work for the student and research worker, presenting a large collection of frequently used data in convenient form.

INTRODUCTION TO THE HISTORY OF SCIENCE. V. 2 in two parts. From Rabbi Ben Ezra to Roger Bacon. By George Sarton. Publ. for the Carnegie Institution of Washington, as Pub. No. 376, by Williams & Wilkins Co., Baltimore, 1931. 1251 p., 11x7 in., cloth, $12.00.——A masterly survey of the growth of scientific thought and achievement over the twelfth and thirteenth centuries. An inventory of mediaeval science, East and West, on a scale never before attempted, indispensable to students

## ENGINEERING SOCIETIES LIBRARY

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

INDEX TO A.S.T.M. STANDARDS AND TENTATIVE STANDARDS. Phila., American Society for Testing Materials, 1931. 103 p., 9x6 in., paper, free.——Combined index, covering all A.S.T.M. standards in effect in Sept. 1931, telling in which publication they can be found, and making it easy to determine whether a particular specification exists and where it may be found.

APPLIED GYRODYNAMICS. By E. S. Ferry. N. Y., John Wiley & Sons, 1932. 277 p., 9x6 in., cloth, $4.00.——The purpose of this work is to present gyrodynamics to the acquaintance of engineers and students having the mathematical equipment of the ordinary graduate of engineering or physics. It considers such important devices as the gyrohorizon, the gyrosextant, the gyrocompass and gyrostabilizers for ships and monorail cars.

NEW CONCEPTIONS OF MATTER. By C. G. Darwin. N. Y., Macmillan Co., 1931. 224 p., 9x6 in., cloth, $3.00.——This book, based on Prof. Darwin's Lowell Institute lectures in 1931, is a clear description of the broad features of the new mechanics in non-technical language without the use of mathematics. The book is not light reading but calls for no technical knowledge upon the part of the reader.

THEORETICAL PHYSICS. V. 1. Mechanics and Heat. Newton-Carnot. By W. Wilson. N. Y., E. P. Dutton & Co., 1931. 332 p., 9x5 in., cloth, $6.00.——Prof. Wilson's aim is to present an account of the theoretical side of physics which will be sufficiently comprehensive to be useful to students, without being too elaborate and voluminous. This volume, the first of three, deals with mechanics and heat. The subjects are developed according to their historical growth.

EINFUHRUNG IN DIE THEORIE DER SCHWACHSTROMTECHNIK. By J. Wallot. Berlin, J. Springer, 1932. 331 p., 10x7 in., paper, 21.50 RM; bound, 23 RM.——An introduction to the theory of telegraphy and telephony based upon courses given in the central laboratory of Siemens & Halske to the laboratory staff. A book on concepts and developments of weak-current theory in an easily understandable form.

DIE ELEKTRISCHEN MASCHINEN; Bd. 1. Allgemeine Grundlagen, by M. Liwschitz. 2nd edit., 381 p., 18 RM. Bd. 2. Die elektrischen Maschinen, by M. Liwschitz and H. Glöckner. 1st edit., 306 p., 19 RM. Leipzig & Berlin, B. G. Teubner, 1931. 9x6 in., cloth.——To give the young engineer an understanding of the relationship between natural laws and electrical machine behavior so as to equip him for advanced study and independent work as a designer.

# Industrial Notes

**Allis-Chalmers Appoints L. W. Grothaus.**—Announcement has been made that L. W. Grothaus succeeds C. E. Searle as general representative of the Allis-Chalmers Manufacturing Company, Milwaukee. Mr. Searle resigned on January 31 to become vice-president of an eastern firm. Mr. Grothaus has been affiliated with the Allis-Chalmers Company since 1904. Prior to his promotion he was assistant manager of the electrical department.

**American Transformer Appointments.**—Announcement has been made by the American Transformer Company, Newark, N. J., of the appointment of two sales representatives. Edgar M. Moore Company, Farmers Bank Building, Pittsburgh, will handle sales of AmerTran industrial transformers in western Pennsylvania, southern Ohio, and West Virginia. Theodore F. Mueller, 3-260 General Motors Building, Detroit, will handle sales of all AmerTran products in the entire state of Michigan with the exception of the upper peninsula.

**Steel Tubes Announces Appointment.**—Morgan P. Ellis has been appointed vice-president in charge of all sales. Murray J. Whitfield is general sales manager of the electrical division in charge of sales of "Steeltubes" electrical metallic tubing (thin wall conduit).

**General Electric Orders in 1931.**—Orders received by the General Electric Company during the year 1931 amounted to $252,021,496, compared with $341,820,312 for 1930, a decrease of 26 per cent, President Gerard Swope has announced. Orders for the quarter ended December 31 amounted to $49,321,480, compared with $74,168,480 for the last quarter of 1930, a decrease of 34 per cent.

**Insulator for Universal Clips.**—Rubber insulators of a new and improved style are now being offered for Universal clips. These new insulators have an extended tubular portion at the rear which insures that any bending of the cord near that point takes place on a relatively large arc, thus preventing breakage of the copper conductor. A further feature of the new insulator is an interior constricted ring of rubber, which serves to keep the insulator from slipping down on the cord when the clip is applied to a terminal. An interior arrangement of the insulator makes it possible to mount it on the clip either with the nose exposed or with the clip completely enclosed, so that the nose is flush with the outer opening. This latter position is often desired, as it prevents the clips short-circuiting with each other when knocking about on the test floor, test bench or laboratory table. Mueller Electric Co., 1583 East 31st St., Cleveland.

**Electrolytic Condensers for Capacitor Motors.**—With considerably improved characteristics due to a radical departure in the formation of the oxide dielectric film on the aluminum foil, the small electrolytic condenser is ready to go outside the radio field and find many applications in electrical and industrial functions according to William Dubilier, pioneer condenser designer and manufacturer. "Recently, our engineers have developed a new and radical means of forming the oxide film on the electrolytic condenser foil," states Mr. Dubilier. "Not only do we obtain a tougher dielectric film, capable of higher working voltage and faster comeback in the event of a breakdown, together with a more favorable power factor, but the very nature of our new forming process conserves the electrolyte for a longer service life. We now find it possible to employ electrolytic condensers for capacitor motor functions. The 110-volt or 220-volt a-c. electrolytic units are proving satisfactory for starting and intermittent service. The fact that a very high capacity is obtainable at a very low cost, makes these capacitors highly desirable today."

**A New Oil Purifier.**—A new type of centrifugal oil purifier for transformer and circuit breaker oil, in which the oil is centrifugally purified under a high vacuum, has been introduced by the Sharples Specialty Company, of Philadelphia, under the registered trade name of "Deoxator." It is claimed that this machine not only removes any free air in the oil, but also removes 90% of the oxygen in solution and any dissolved moisture. The removal of the oxygen in solution tends to reduce the formation of sludge through oxidation while the removal of dissolved moisture produces a dielectric that will last longer.

The Deoxator can be used effectively for the following work: for filling and "drying out" new equipment; for filling Inertaire type transformers to eliminate second blowing with nitrogen; for centrifuging oil in transformers that are designed to prevent air contact and preventing the introduction of any air whatsoever into the transformer; purifying oil for oil filled cables; purifying oil in subway type transformers that are sealed up tight; for producing a purified oil with less sludge forming tendencies and having a more persistent dielectric. In the Deoxator the centrifuge bowl is still used to remove free water and sludge while the vacuum removes dissolved moisture and oxygen in solution. Unless the free water is removed first by the centrifuge bowl, the vacuum efficiency is destroyed by the surplus water vapor.

# Trade Literature

**Motors.**—Bulletin 173, Part 4, 2 pp. Describes brush-riding repulsion-induction motors. Wagner Electric Corp., 6400 Plymouth Avenue, St. Louis.

**Indoor Bus Supports.**—Bulletin GEA-924B, 32 pp. Describes in detail various types of bus supports available to meet the requirements of various installations. General Electric Co., Schenectady, N. Y.

**Aluminum Bus Bars.**—Booklet, 20 pp., "Channeluminum Electrical Conductors of Alcoa Aluminum." Includes illustrations and diagrams as well as installation photographs. Aluminum Company of America, Pittsburgh, Penna.

**Constant Voltage Regulators.**—Bulletin 5501. Describes Ward Leonard constant wattage voltage regulators for eliminating the distortion and inaccuracies of photo-cell devices resulting from voltage fluctuation. The device is a voltage transformer and regulator combined, reducing the a-c. line voltage to that required by the exciter lamp, and maintaining the exciter lamp voltage constant regardless of instantaneous fluctuations in line voltage. The design of the regulator is such as to compensate for variations in lamps of the same nominal rating and to correct for the increase in lamp resistance due to aging. The regulators are used to maintain constant voltage with various types of loads, constant or variable, with leading or lagging power factors. Ward Leonard Electric Company, Mount Vernon, N. Y.

**Thrustors.**—Bulletin GEA-1262B, 24 pp. Describes G-E Thrustors for producing a straight-line, constant-pressure thrust from an electric motor drive. There are two general fields of application of these units: (1) to supply pressure and actuate lever mechanisms, (2) to replace muscular effort with electric control on foot- or hand-operated machines. The device can be installed easily on practically any type of equipment. It handles clutches and brakes in such a way as to prevent strain and excessive wear; it can be utilized to increase production; to afford greater safety for the workman, and to give complete electric control. Typical installations are illustrated on punch presses, spot welders, hoists and elevators, valves, conveyors, and for opening and closing sliding, swinging and lift doors. General Electric Company, Schenectady, N. Y.

### Front Cover

Reputedly the only one of its kind in the United States, the marble dome of the Rhode Island Capitol is floodlighted by seven groups totaling 109 projectors, 67 kw. in lamps. Providence is host city to the May meeting of the North Eastern District, and the prominently lighted dome of the Capitol may serve well as a landmark for those motoring in at night.

Officers and Committees (For complete listing see p. 71-76, January 1932 issue of ELECTRICAL ENGINEERING.)

ELECTROCHEMISTRY represents a fruitful field for the application and utilization of electric power; furthermore it holds many opportunities for the young electrical engineer with some knowledge of chemistry. *p. 238–242*

EDUCATION "after college" has met with surprisingly successful results according to a report issued recently by the chairman of the educational committee of the Institute's Chicago Section. *p. 280–281*

PROPER control of lines interconnecting two electric power systems is a problem in load control rather than frequency. Special equipment has been designed to accomplish this and has been found to operate satisfactorily with frequency control equipment on one of the systems. *p. 256–260*

COMMITTEES already have been appointed and are busy preparing for the coming A.I.E.E. summer convention to be held in Cleveland, Ohio, in June. *p. 275*

THE de Laszlo portrait, for which President Hoover recently sat, was unveiled in the Engineering Societies Building, New York, on February 15. *p. 273*

IF REGISTRATION records are an accurate indication, the district meeting held recently in Milwaukee may be classed as an unqualified success. *p. 270–271*

EXPERIMENTS show that of the total current passing through the body during electric shock, only a small percentage actually passes through the heart. *p. 242–244*

PAPERS presented at the recent A.I.E.E. winter convention were liberally discussed by those attending; as much of this discussion as space permits is presented in summarized form in this issue. *p. 272–279*

MORE than 1,200,000 synchronous electric clocks are said to have been sold in 1930. Tests over a period of several weeks show the maximum deviation of these instruments to be only 44 sec. *p. 228–232*

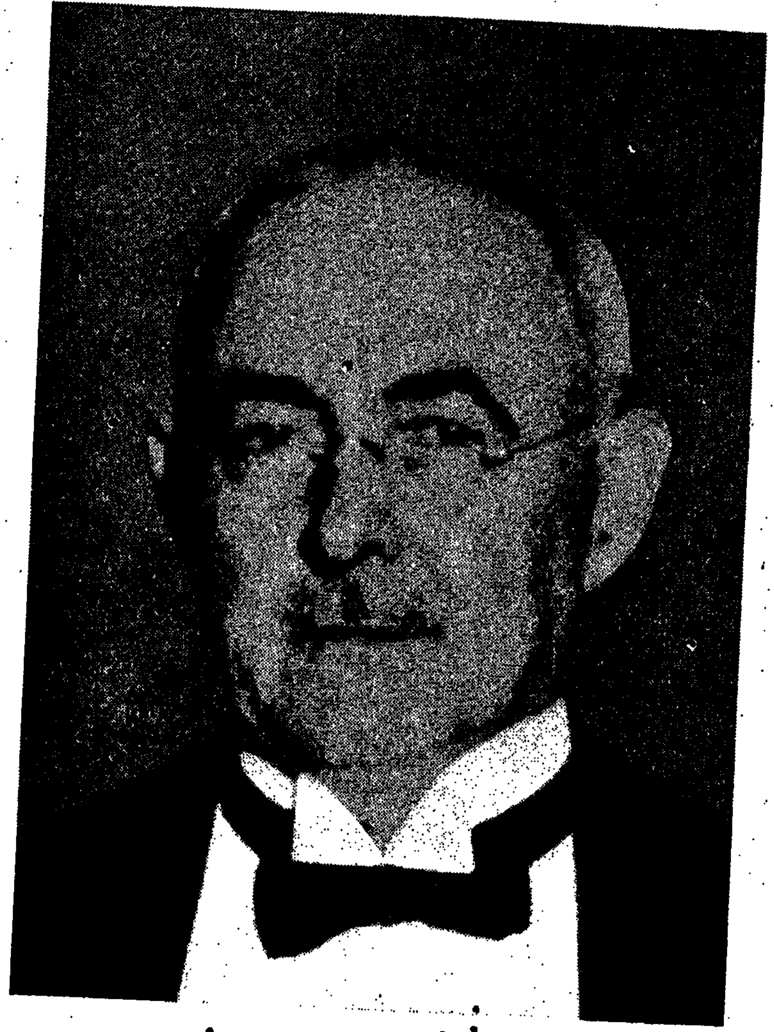
STABILITY studies of metropolitan electric power systems often pave the way for more reliable or economical system layouts. Curves have been developed by which the transient stability may be determined for any system of this type. *p. 232–237*

A RECENT survey shows that 6 per cent of the total railway mileage of the countries of Western Europe are electrified. This percentage is increasing yearly, and despite the present economic crisis 1,042 more route miles now are under construction or authorized. *p. 244–252*

PLANS are practically complete for the Providence meeting of the A.I.E.E. North Eastern District. A well-rounded program with many attractive features has been arranged. (*p. 268–270.*) Interpretive abstracts of all technical papers to be presented appear in this issue. *p. 263–267*

# FREDERICK LANE HUTCHINSON

## 1866—1932



Born at Elizabeth, N. J., April 2, 1866, to Elizabeth (Pring) and John Hutchinson; graduated from Cornell University, 1893; with the Westinghouse Electric & Manufacturing Company from 1893 to 1901; became an Associate of the Institute in 1894; manager of publications for the C. W. Hunt Company of New York, 1901–2; advertising manager for the National Electric Company of Milwaukee, 1902–3; sales manager for the same company, 1903–4; took up special work on the Institute TRANSACTIONS in 1904; appointed Assistant National Secretary in 1908; became National Secretary in 1912; transferred to grade of Member of the Institute, 1913; married Grace Lawrence Duryee of San Diego, Calif., June 27, 1921; represented the Institute at the World Power Conference, London 1924, and at the World Engineering Congress, Tokyo, 1929; died Friday, February 26, 1932.

A MEMORIAL RESOLUTION, adopted by the Executive Committee of the American Institute of Electrical Engineers,—

**WHEREAS: The death of Frederick L. Hutchinson has removed from the American Institute of Electrical Engineers one of its most devoted members and a leader of marked ability and high ideals,**

**WHEREAS: During his service of twenty-eight years as a member of the staff, including twenty years as national secretary, he worked unceasingly and effectively for the best interests of the membership and the advancement of the entire engineering profession, exhibiting at all times remarkable enthusiasm, unselfishness, and wisdom,**

**WHEREAS: His delightful personality, his deep interest in the wide range of activities of the Institute and organizations with which it cooperated, his keen grasp of all questions involved, and his unfailing tact on all occasions, won the respect and admiration of a multitude of friends, be it therefore**

**RESOLVED: That on behalf of the membership, the executive committee hereby expresses its profound sorrow at the death of one of the Institute's outstanding leaders, and extends to the members of the family of Mr. Hutchinson its deepest sympathy, and be it further**

**RESOLVED: That these resolutions be inscribed in the minutes of the Executive Committee and a copy be transmitted to the members of Mr. Hutchinson's family.**

# Synchronous Electric Time Service

**Commercial a-c. time service has been made possible by the development of a self-starting synchronous motor and of a master clock to indicate deviations of power system frequency from normal. Construction, accuracy, and application of various types of these devices are described in this article.**

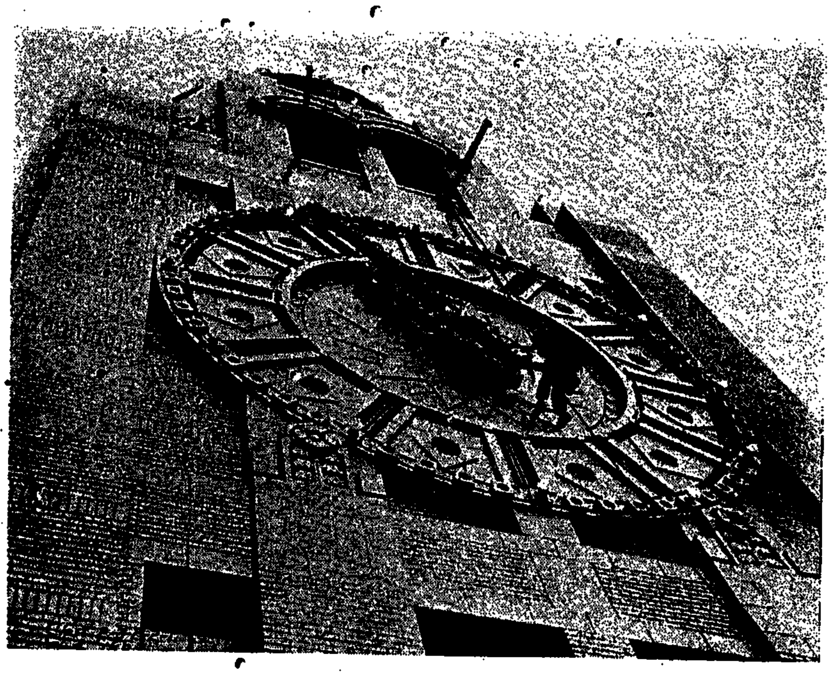

Fig. 1. Dial of a large synchronous tower clock. Illuminated at night, the characters around the circumference flash in succession to indicate seconds

BEFORE the beginning of the present century there were a few individuals who realized the possibility that commercial alternating current, by means of its recurring pulsations, might be used in some manner to measure time; but dreams of this nature did not materialize in practical performance.

Up to 1916 there was no commercial a-c. system in existence in which generator speed was regulated with sufficient accuracy so that the current could be used for the purpose of indicating time by means of synchronous clocks. At that time two devices were brought out which in the succeeding years made possible commercial a-c. time service.

The first of these devices was a self-starting synchronous motor utilizing residual magnetism to permit a rotor to start and run at synchronous speed. This type of motor differs from all the common forms of a-c. motors in that eddy currents induced either in the mass of the rotor or in some form of winding upon the rotor are not utilized to start the rotor from rest. Instead, the rotor is made of such permanent magnetic material and is so proportioned with respect to the field that remanent magnetic poles are set up in the rotor material by the a-c. magnetism of the field in such a manner as to cause the desired motion. Such a motor is sometimes known as a hysteresis motor. Fig. 2 shows a view of a recent model.

The hands of a clock were connected by a gear train with the first of these self-starting synchronous motors and this clock, supplied by current from the local electric light system, was compared with standard time at intervals over a period of several weeks. The new motor driven clock proved to be a very inferior timekeeper, developing daily errors as great as 5 or 0 min., thus proving the need of greater accuracy in ie average frequency of the power supply if it were be used for timekeeping.

By observing these daily errors it was easy to compute the average value of the system frequency. There are 1,440 min. in a day and the gearing of the clock was such that if the frequency had been exactly 60 cycles, there would have been no time error; a 1 per cent error in average frequency (0.6 cycles at 60 cycles) would mean 1 per cent error in the time of the clock, which amounts to 14.4 min. per day. The actual, computed error in the average frequency as determined by these observations is shown in the upper curve of Fig. 3 which was originally published in the article, "Clocks in the Field of Electric Light Appliances" in the N.E.L.A. *Proc.*, 1917, Commercial Sec., p. 641.

The second device consisted of an indicating instrument that would show to a generating station operator directly in terms of time, deviations of average frequency from standard. Guided by this instrument, an operator could so regulate the speed of his generators as to maintain such small deviations from standard average frequency that the alterations could be used to measure time for all ordinary commercial purposes. Fig. 4 shows the dials of a type of master clock which is in common use. The large dial in the center has two hands, one black and the other gold. The black hand makes a revolution on the dial every 5 min., its rate of motion being regulated by an accurately adjusted pendulum beating seconds. The gold hand is driven by a gear train directly from one of the Telechron self-starting motors. The gear ratio is such that when the average frequency is correct, this hand will also make one revolution in exactly 5 min.

The two hands are started off together, and so long as the average frequency remains correct, will keep together with no visible angle between them. An error in the average frequency will cause the gold hand to move slightly faster or slower than the black hand and they will become separated. The angle of separation will be a direct visible measure of the error in the integrated alternations, which may be conveniently called the system time. If the gold hand is ahead, this will show that the system time is fast; if behind, that it is slow.

---

Based upon "Synchronous Electric Time Service" (No. 32-40) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25–29, 1932.

An error in the average frequency as small as 1/60 cycle will cause a spread of 1 sec. between the two hands of the master clock in 1 hr. If such an error continues, the spread will continue to increase as time passes. The accuracy of the indication is limited only by the timekeeping precision of the pendulum itself. When carefully regulated this is better than 1 sec. per day, or an absolute precision of about one part in 100,000.

When the operator at the generating station which is regulating frequency adjusts the turbine governors from time to time so as to keep the black and gold hands of the master clock together, he automatically causes all other synchronous motor clocks on the same system to keep correct time. The lower curve of Fig. 3 shows the great improvement in the average frequency value obtained after the first master clock installation.

The standardization of average frequency is of great value to the power companies in the following ways:

1. By improving the service furnished manufacturing establishments, insuring more uniform speed of motor driven machinery and generally assuring the quality of the product.
2. By facilitating interconnection with other power companies which have correspondingly standardized their frequency.
3. By enabling power companies to use synchronous motor movements in their maximum demand meters and graphic recorders, thereby obtaining more accurate and synchronized records at lower cost of maintenance.

Before master clocks were available, the inherent errors in frequency indicators were sufficient to handicap operators on interconnected systems in their efforts to equalize the frequency preparatory to synchronizing the two systems, and to lead to controversy as to the true value of the frequency after the two systems were synchronized.

Master clocks have been adopted generally by the power companies of the United States for the purpose of regulating frequency. At the present time it is estimated that the regulation of the current to over 90 per cent of the consumers' meters in this country is guided by these master clocks.

The accuracy which may be expected at present from a synchronous electric clock is indicated by the records shown on Fig. 5. The records shown on this chart are taken from four typical very large interconnected systems east of the Mississippi River. The ordinates of the curve in each case are seconds deviation from standard time, and the abscissas, weeks over a period of 5 months. The solid line through the center of each curve represents standard time, and the two points plotted for each day at the top and bottom of the band represent the maximum range of the deviations from standard for that day. The widest deviations shown are 44 sec. fast or slow, which means that on these systems a synchronous clock set absolutely accurately with standard time, did not indicate incorrect time more than 44 sec. fast or slow through the period plotted. The records of the two systems which show the smallest departure of standard time indicate that a clock operating on these systems would never be more than 9 sec. fast or slow. There are few uses of time which justify higher accuracy, and even the worst of these records is far superior to that of previous types of commercial clocks.

Some power companies throughout the country may be giving better than the best time service indicated on this chart; probably there are some permitting wider variations. Practically all power companies, however, are giving sufficiently accurate frequency regulation to provide far better time on synchronous clocks than previously available on commercial clocks.

All factors in power system development are tending to require continued improvements in frequency regulation. As a matter of fact the very large interconnected systems have so much momentum stored

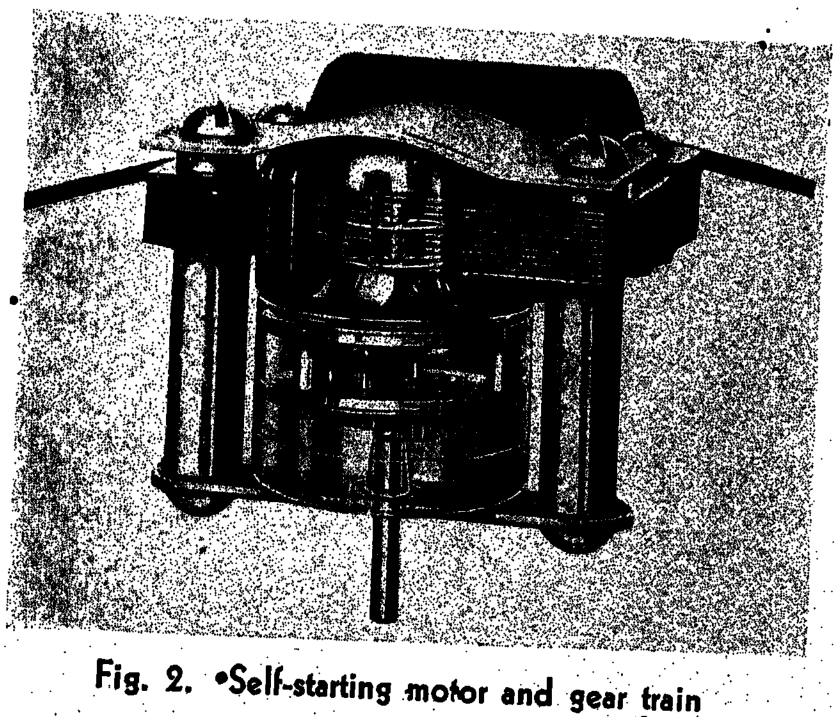

Fig. 2. Self-starting motor and gear train

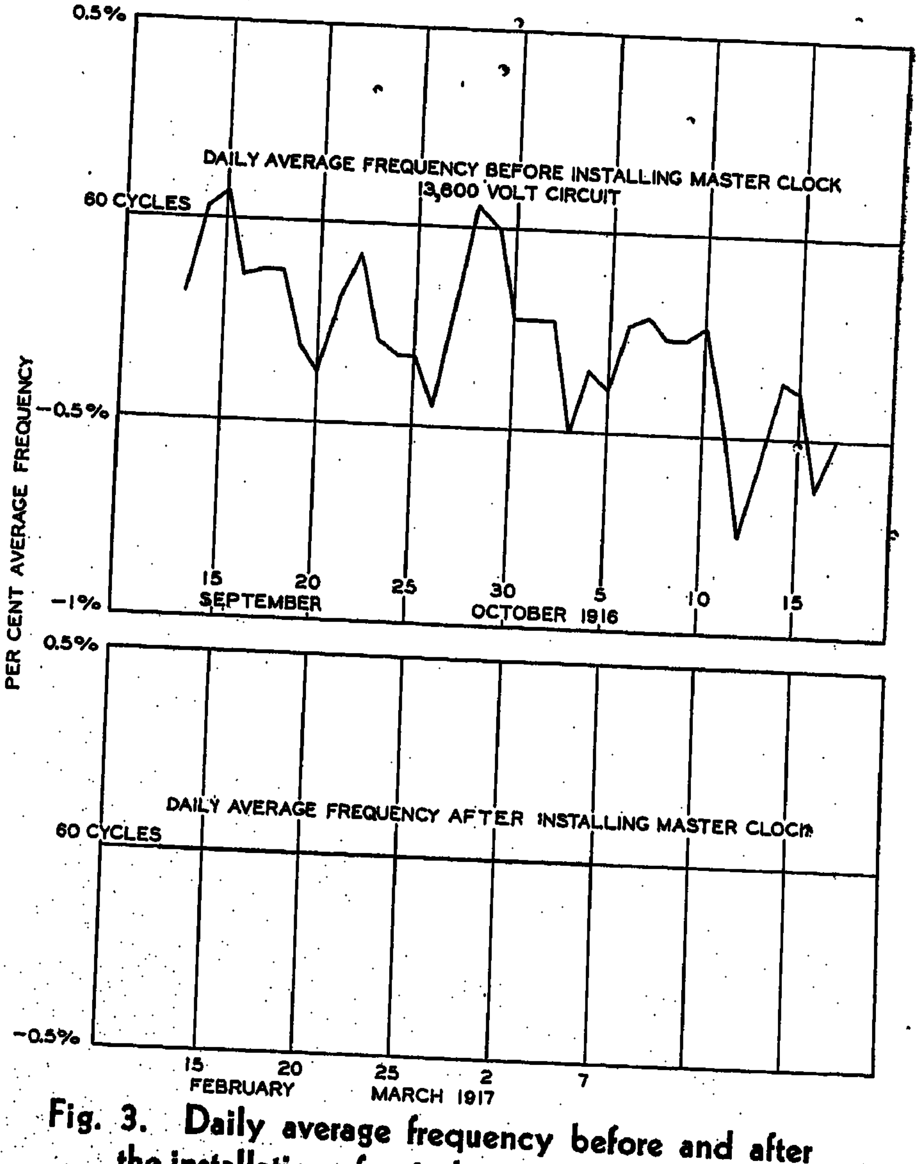

Fig. 3. Daily average frequency before and after the installation of an indicating master clock

in rotating equipment (generators, motors, etc.) that when properly adjusted at the beginning of a flat load period, they will give almost perfect time with no adjustment of governors for speed. Over the irregular portions of the load curve, however, governor adjustment is necessary and much work is being done at present to divide the burden of this regulation on large interconnected systems between the various power companies by the use of automatic frequency control to supplement the master clocks. When perfected and applied, these instruments will undoubtedly reduce the system time error to insignificant values of the order of 1 or 2 sec.

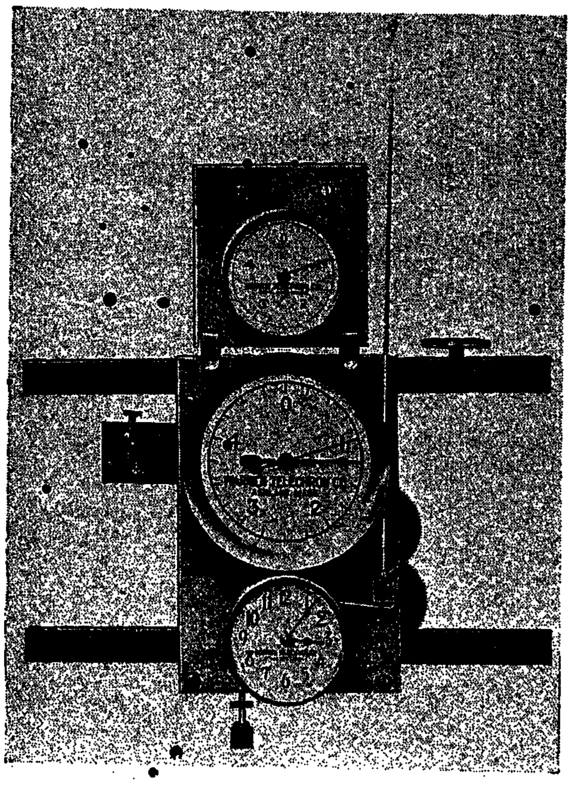

**Fig. 4. Operating dials of a common type of master clock**

## Synchronous Clock Motors

About 1928, twelve years after alternating current regulated by means of master clocks as illustrated in Fig. 4 became available, there appeared on the market the first of several new varieties of synchronous motors suitable for use in clocks. These motors may be divided into two classes; non-self-starting and self-starting.

The non-self-starting motors, of which there are several kinds, generally have toothed, soft-steel rotors. The usual stator construction is bipolar with teeth on each pole corresponding to the spacing of the rotor poles. In all multi-polar motors of the common varieties the speed is found by dividing the number of current alternations per minute by the number of rotor or stator poles. In nearly all cases no attempt is made to introduce a rotating component into the field. A common arrangement of rotor and stator is shown in Fig. 6. On account of the difference in magnetic reluctance between rotor positions, where the poles do or do not correspond with the stator poles, a strong reactance torque exists when the rotor is at rest. This tends to prevent the rotor from starting; but when running at synchronous speed, tends to keep it at that speed.

It is somewhat difficult to spin such a rotor by hand so as to cause it to lock into synchronism with the alternating field unless some means is provided which will permit a sudden phase shift of the rotor poles as the rotor speed passes through its synchronous value. Among the satisfactory schemes for accomplishing this result is the use of loosely coupled fly-wheels on the rotor shaft or spirally arranged rotor poles with means for the axial shifting of the rotor in the field. Also, when started by hand, mechanical launching devices sometimes are used to bring the rotor up to approximately synchronous speed automatically.

The self-starting synchronous clock motors which have appeared within the last few years utilize a-c. fields with rotating components brought about by the use of shading coils. Most of these motors have multi-polar rotors with some form of squirrel-cage winding or a copper element wherein Foucault currents are induced by the rotating field. Like ordinary induction motors, such motors get their starting torque through the reaction of the Foucault currents in the field. Synchronous driving torque in these varieties of self-starting motors is produced by polar projections of the steel rotors or by a separate polar element loosely coupled to the rotor shaft. One variety of the recent self-starting synchronous motors utilizes remanent magnetism for starting and for synchronous operation.

Any of the rotors described heretofore may be used to drive the hands of a clock through a simple train of gears. Two forms of such gear trains are in common use, one composed entirely of spur gears and the other utilizing worm gears and worms. On account of the greater efficiency of transmission, a spur gear train is better for large clocks, but for small clocks the other mechanism is satisfactory. Frequently the high-speed gears of a spur-gear train are made of nonmetallic material so as to run more quietly, and the motor or the whole clock movement is usually mounted on cushioning material so as to reduce the a-c. hum. Some clocks are much quieter than others, depending upon the rigidity of the field laminations and the design of the moving parts.

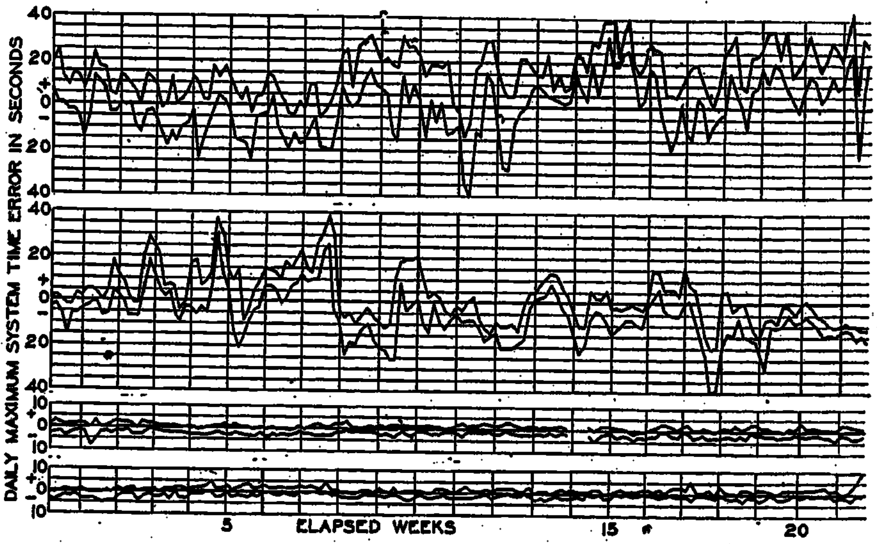

**Fig. 5. Maximum daily system time errors of four large power systems**

Any one of the motors mentioned is adequate to drive the hands of a clock dial 12 in. or less in diameter. The actual output required for this purpose is exceedingly small. If the clock hands are balanced and the gear train is fairly efficient, not more than one twenty-millionth of a horsepower is needed for a 12-in. dial. The power output of the various motors ranges from less than one-millionth of a horsepower to more than one-ten thousandth of a horsepower. The larger amount has been found adequate to drive tower clocks 10 or 12 ft. in diameter. The power output of these motors seems exceedingly small as compared with commercial motors used for other purposes; nevertheless it is, fully adequate for this timekeeping duty, and is many times greater than the power of ordinary spring clock motors.

The electric input to these motors is generally in the neighborhood of 2 watts, but as the power factor is low, the voltamperes vary from three to six. Obviously the efficiency of these motors is very low indeed, amounting to a fraction of 1 per cent. However, the power used is so little (17 kw-hr. per year or approximately $1.00 worth) that this feature is of minor importance.

Most synchronous motor clocks are provided with some form of indicator visible through a small hole in the dial. In clocks which are not self-starting this indicator, by its continuous motion shows that the clock is in operation. After an interruption in the current, the motion of the indicator stops permanently. In self-starting motor clocks of the Telechron brand, the indicator back of the dial shows a steady white target as long as the current flows. This target changes to red and remains so after an interruption in the current supply, although the clock of course starts and continues to run as soon as the power is restored.

Inasmuch as most kinds of synchronous motor clocks either will stop permanently or show errors after current interruptions, it is reassuring to know that system interruptions are rare in our thickly settled districts. Often these clocks continue to show correct time within a very few seconds for many months, even for years. In order to provide against the rare stopping of the hands because of interruptions, clocks have been available for many years which have auxiliary spring movements. These movements appeared more necessary in the beginning before a-c. service had become as reliable as it is today.

The successful operation of synchronous motor clocks is quite independent of certain influences which are detrimental to other clocks, such as level position, vibration, and ordinary temperature variations. Extreme temperatures near zero fahr. will stop some kinds of clock motors, but other varieties will operate well below zero.

## APPLICATIONS

Application of these small clock type synchronous motors to many devices and instruments has been going on ever since these motors became available. The first users were the power companies themselves who had many instruments and meters, especially those of the maximum demand type which required timekeeping elements. The spring clocks used for these purposes were inaccurate, troublesome, and costly to maintain. This was especially true because they needed frequent winding and often were located at distant points. The instrument load was sometimes too great for a spring clock to handle with accuracy. As soon as the motors were substituted for the spring clocks there was a great gain in accuracy and reliability and the costly winding was eliminated. It then became possible to redesign the instruments so as to give still better performance.

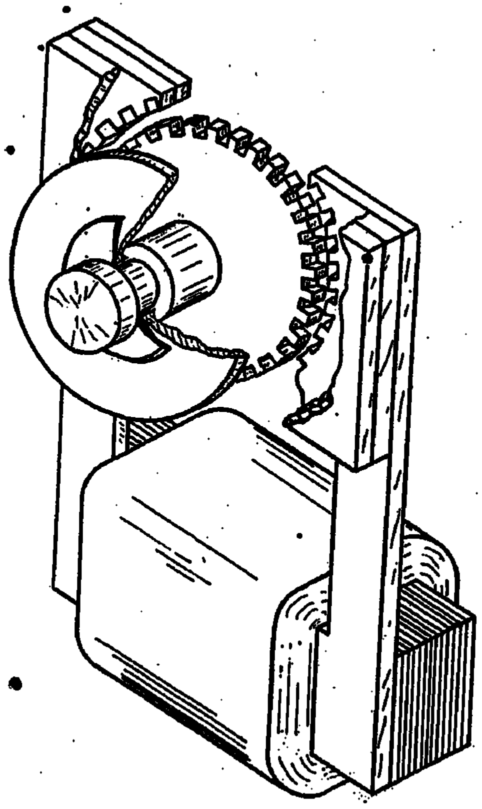

Fig. 6. One type of non-self-starting synchronous clock motor

Gradually nearly all the makers of instruments began using synchronous motors in place of spring movements, until now the list of such motor driven instruments is nearly a complete catalog of devices in which the measurement of time is involved. The largest class of these motor driven instruments is perhaps the graphic recording type. The load of driving a paper chart, especially of the strip type, is very great for a spring clock but comparatively trifling for a synchronous motor. Moreover, the motor can handle a roll of paper so as to make a continuous record for weeks or months without regard to winding. There are also many kinds of instruments which do not make a record but serve to control or actuate, and synchronous motors have been incorporated advantageously into certain forms such as time switches, temperature controllers, traffic signals, etc.

There is a large and important class of timing devices exclusive of ordinary clocks. Among them are numerous kinds of time and cost recorders, program machines, time stamps, etc., wherein synchronous motors have gradually been replacing spring clock movements. In many cases this change has made it possible to eliminate local master clocks, batteries, and expensive wiring.

In building installations, where synchronous clocks, or timing devices driven by synchronous clock motors are numerous it is usual for the customer to provide a so-called "resetting device" or a duplicate source of a-c. energy to guard against the effect of interruptions in the supply of current. In all such installations a separate wiring system is used, connected with the public service system through a suitable switchboard.

The resetting device automatically measures the duration of an interruption and after the current is restored, applies higher frequency or otherwise speeds up the clocks until again they are correct.

The problem of driving very large tower clocks by means of self-starting synchronous motors is much less difficult than that formerly involved in the use of conventional pendulum tower clock movements. Of course it is necessary for the gears and shafts to be very strong because the stresses due to the great weight of the hands and the pressure of the wind are rather high. Fig. 1 shows a tower clock movement installed on the Williamsburgh Savings Bank at Brooklyn, N. Y., where each of the four dials is 26 ft. in diameter and the hands alone weigh 700 lb. per pair. The hour hand sleeves of this clock are of steel and their outside diameter is 4 in. The power required to drive these hands during a heavy wind is less than 0.001 hp. The motors used have a very large surplus power margin.

Since their conception in 1916 synchronous motor clocks and timing devices have increased in use with extraordinary rapidity, especially during the last few years. According to estimates more than 1,200,000 synchronous motor clocks were sold during 1930. There seems little doubt that during the coming years spring and weight driven clocks will be replaced in large measure by the new a-c. timekeepers, which have proved superior in every important respect.

# Stability Solution for Metropolitan Systems

**General stability curves are given in this article by means of which the transient stability during fault may be determined for any metropolitan type system. The results are obtained as the permissible fault duration in terms of certain indexes of the system and fault. For a given fault only three readings, taken on a d-c. calculating board, are required, the solution being obtained without the necessity of investigating the electromechanical oscillations.**

STABILITY studies of metropolitan type systems may be profitable not because instability has been a serious operating problem, but because such studies often may permit a more reliable or more economical system layout to be utilized safely. Transient stability, that is, stability during faults, has been found to be the limiting condition for stability of metropolitan type systems, all available information indicating that static instability is never experienced in normal operation of this type of system. Under fault conditions the measure of the degree of stability is the time a fault may be permitted to remain on the system without causing one or more generators to lose synchronism. Curves are presented here which permit the ready determination of the permissible fault duration in terms of certain system constants.

These constants may be found for most metropolitan systems from a short-circuit study on a conventional d-c. calculating board. The fundamental premise underlying this method is that setups giving the same values of the system constants or indexes will have approximately the same degree of stability. The curves give the results of studies on hypothetical systems covering the range of the system constants encountered in metropolitan systems. To render this method practical, the number of indexes must be reduced to a minimum. This means that the variations produced by minor influences must be neglected and average values assumed for machine characteristics. It was found that if the scope were restricted to metropolitan type systems, the number of essential indexes could be reduced to three, with means of modifying these three to provide for the variations produced by the more important influences.

In this discussion a metropolitan type of system is considered to be one in which the principal power sources are generators driven by steam turbines and located relatively close to their load centers, with distribution provided by a large number of moderate voltage circuits. The power supply to most metropolitan districts is of this character, but several large districts receive a major part of their power from distant hydroelectric sources which are quite different in character, and for these, individual studies are required. However, if the hydroelectric generating capacity is one-fourth, or less, of the total,

---

Based upon "Generalized Stability Solution for Metropolitan Type Systems" (No. 32-26) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25-29, 1932.

the stability of the other generating sources for faults in their localities still may be analyzed by the methods presented, without serious error.

Metropolitan type systems as above defined are similar in essential characteristics, making generalized studies practicable. The principal features of similarity are as follows:

1. With equal per cent loadings the internal voltages of all generators on the system are practically in phase.
2. Because of the multiplicity of circuits the reactance of the connecting ties holding a generator or group of generators in step with the system does not change appreciably when the fault is cleared.
3. With turbine-generators and short transmission distances, the generator characteristics, no longer being affected by the speed of rotation of the prime mover, line charging current requirements, etc., tend to become fairly uniform in their essential points such as reactances, inertia, and short circuit ratio.

When a fault occurs on a system, all of the generators undergo electromechanical oscillations because of their change in output. Generators which are similarly affected by the fault will react similarly and therefore may be classed as a single unit. In this discussion the term "generator" may indicate either a single machine or a group of machines which react similarly. The most severe faults usually are close to a group of generators and for those cases it is sufficient to consider only two groups of machines, the group most seriously affected or "faulted generator" and the remaining generators.

With the metropolitan type system, the most important factors affecting permissible fault duration are the initial generator output, synchronizing power, and severity of fault. Operation at rated load is the condition usually investigated and this condition has been assumed here, although a factor is introduced to take account of other values of initial load. The remaining two factors may be expressed in various ways, the choice depending upon adequacy and convenience. The index used here for synchronizing power is the over-all reactance between the "faulted generator" and the remaining generators expressed in per cent of the rating of the "faulted generator." The index used for severity of fault is the short-circuit current of the "faulted generator" expressed in number of times rated current, modified if necessary by a factor to take account of fault location.

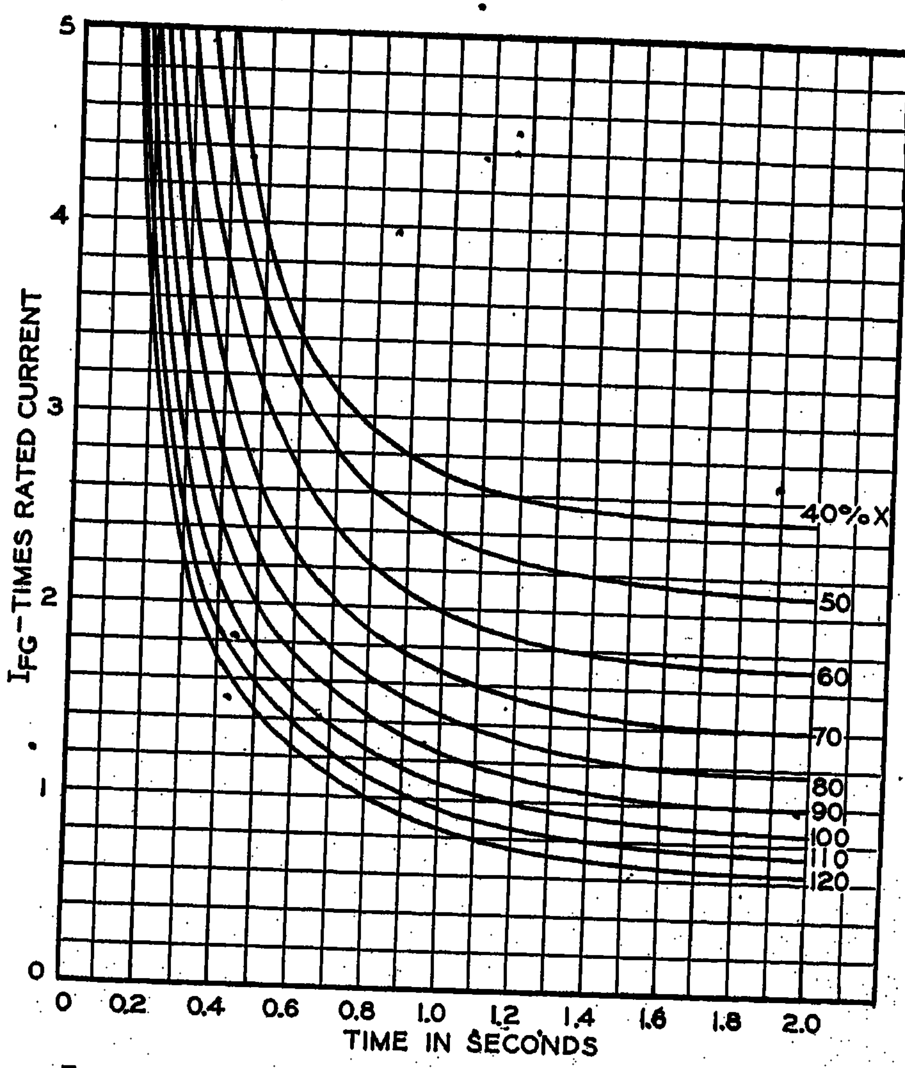

Fig. 1. Principal stability curves. Short circuit current $I_{FG}$ versus permissible fault duration

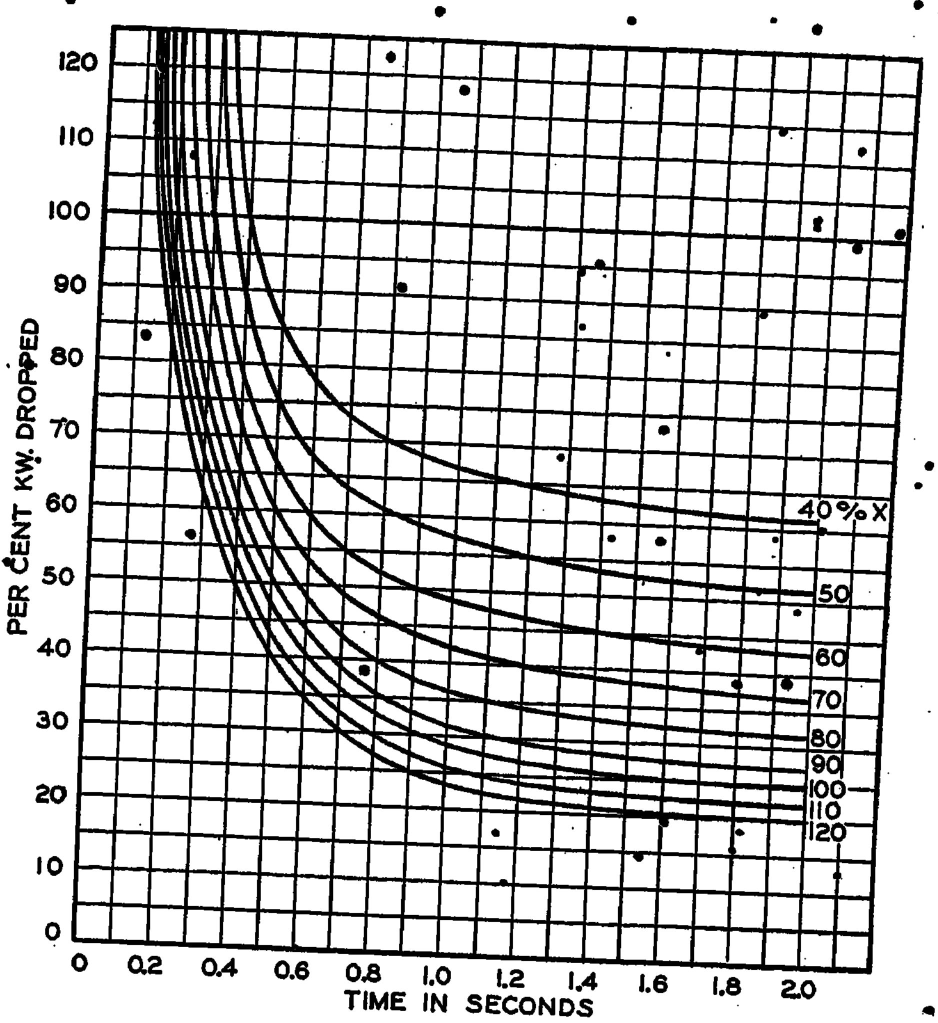

Fig. 2. Auxiliary stability curves. Per cent power dropped versus permissible fault duration

The general stability curves for a generator short-circuit ratio of 1.0 are shown in Figs. 1, 2, and 3. Other curves, not shown, have been calculated for a generator short-circuit ratio of 0.8. These two sets of curves are very nearly identical, and show that generator short-circuit ratio has a minor effect on transient stability. Fig. 1 consists of a family of curves covering the range of over-all reactance $X$ plotted in terms of short-circuit current $I_{FG}$ from the faulted generator, and the permissible fault duration $t$. The curves of Fig. 2, as will be shown later, provide a means of correction for resistance in the fault and for other than rated load on the generator.

The curves of Fig. 1 apply directly to faults at locations electrically equivalent to the generator terminals, such as faults on feeders, just beyond the feeder breaker. To provide for faults occurring at other locations, a close approximation is secured by *dividing* the value of $I_{FG}$ by a factor read from Fig. 3 before entering Fig. 1. This "location factor" is obtained as a function of the ratio of $I_{FG}$ to $I_F$, the total fault current. This ratio will be denoted by $r_{FG}$.

## METHOD OF APPLICATION

The application of these curves will be demonstrated by an example. A typical metropolitan type system is shown schematically in Fig. 4 with reactances as indicated. A fault at point $M$ will be considered. A three-phase fault at this location isolates generator $A$ from the remainder of the system for the duration of the fault, and this generator is therefore the one most likely to fall out of step first. Therefore, machine $A$ becomes the "faulted generator," and all other generators including those in the same group with $A$ become the "remaining generators." Fig. 4 under these conditions reduces to Fig. 5. This reduction may be carried out analytically or by the use of the d-c. calculating board. In the latter case the actual reduction to the simplified form need not be completed, as the necessary indexes may be obtained from the current readings necessary for the reduction. From the simplified figure, the over-all reactance $X$ between the faulted generator and the remaining generators is equal to $27 + 15 = 42$ per cent. This reactance must be based on the kva. rating of the faulted generator in all cases, and if the reactances are set up on some other base they must be converted to this base. To determine the total fault current $I_F$, the branches on each side of the fault are paralleled giving $\dfrac{27 \times 15}{42} = 9.65$ per cent. The total fault current therefore is $\dfrac{1}{0.0965} =$ 10.4 times the rating of generator $A$. The fault current $I_{FG}$ supplied by the faulted generator is $\dfrac{15}{42} \times 10.4 = 3.7$ times rated current. The ratio of $I_{FG}/I_F$ gives $r_{FG}$ as 0.357. The essential indexes are thus

Over-all reactance $X$ = 42 per cent
Current from faulted generator $I_{FG}$ = 3.7 × rating
Ratio $I_{FG}/I_F = r_{FG}$ = 0.357

The location factor is obtained from Fig. 3, entering the curve at $r_{FG} = 0.357$ and interpolating for $X = 42$ per cent, giving a value of 0.7. The adjusted value of $I_{FG}$ is then found to be 3.7 divided by 0.7 = 5.3. The permissible fault duration now may be read from Fig. 1 for $I_{FG} = 5.3$ (extrapolated) and $X = 42$, and is found to be 0.39 sec.

If the d-c. calculating board is used, the indexes may be found directly. With the system set up without the fault, generator $A$ is connected to the positive bus, its transient reactance being included as part of the system, and the remaining generators connected to the negative bus in a similar manner. The current flowing from generator $A$ now is read and converted to number of times rated current for this generator. For this case the value is found to be 2.38. The reciprocal of this value expressed in per cent is $X$ and of course is 42 per cent as before. The remaining generators now are removed from the negative bus and connected to the positive bus and the fault applied by connecting point $M$ to the negative bus. The fault current and current from generator $A$ then are read and converted to number of times rated current of generator $A$. This gives the same result as was obtained from the simplified system of Fig. 5, that is, 10.4 and 3.7 times rated current, respectively.

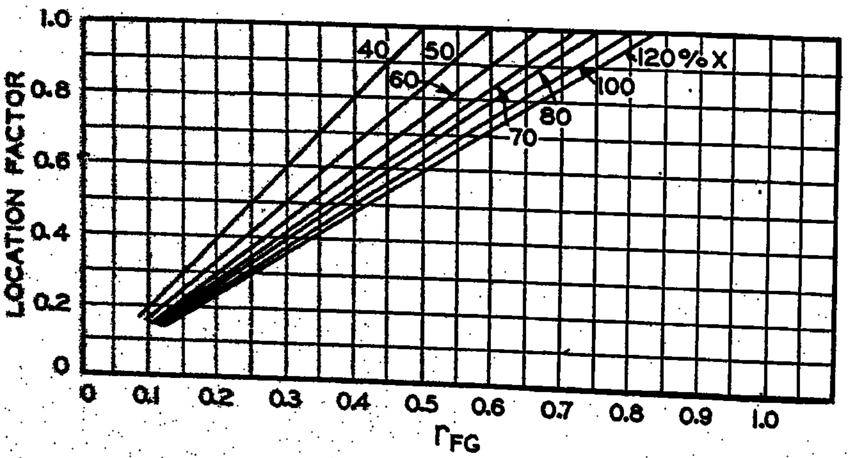

Fig. 3. Location correction factor $r_{FG} = \dfrac{I_{FG}}{I_F}$

If the fault had occurred at point $N$ outside the feeder reactor on a radial feeder instead of at point $M$, the simple equivalent system would appear as in Fig. 6. The reactance of the feeder reactor is assumed as 3 per cent on the feeder rating, equivalent to 30 per cent on the rating of generator $A$, if the feeder rating is one-tenth that of the generator. If the faulted feeder had not been radial and had been tied into the system at the distant end, the equivalent system of Fig. 6 would have been slightly different, although the over-all reactance would still be 42 per cent. It will be found for this case that $r_{FG}$ remains the same since it depends only on the reactance branches adjacent to the generators. Owing to the presence of the 30 per cent reactance in series with the fault, however, the total fault current is greatly reduced and becomes 2.52 times rated current of generator $A$. $I_{FG}$ is found to be 0.9 times rated current and when adjusted for location becomes 1.29. When these indexes are referred to Fig. 1 it is found that the point is beyond the range of the curves and the permissible fault duration is over 2 sec. Two seconds is about the upper limit of relaying time for most systems and the many variables render it undesirable to carry the curves much beyond this figure.

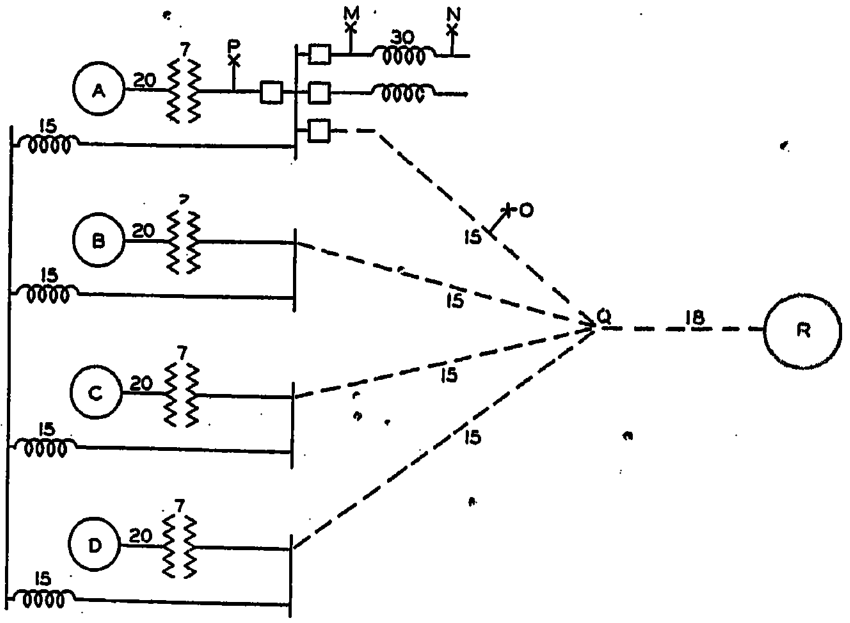

Fig. 4. Typical metropolitan type system

If the fault is at some point $O$ so that it will affect all four of the generators in station $A$ more equally, there is a possibility that this entire group may lose synchronism with the remainder of the system. In such a case, the group should be considered as the faulted generator, and a solution should be carried out expressing all indexes in terms of the rating of the group as a base. This solution should be compared with that for generator $A$ considered as the faulted generator, and the shorter of the two values of permissible fault duration should be taken as the result.

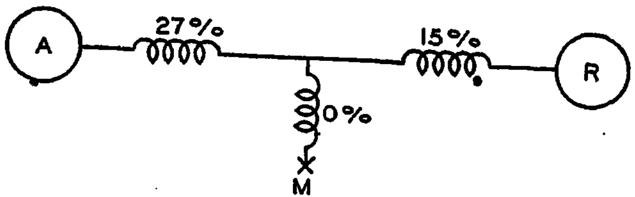

Fig. 5. Simplified equivalent of Fig. 4 for fault at *M*

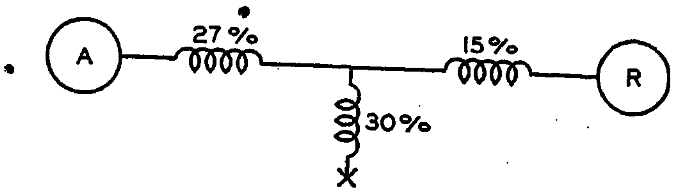

Fig. 6. Simplified equivalent of Fig. 4 for fault at *N*

One more variation will be considered, that of a three-phase fault on the leads of the transformer $A$ at point $P$ close to its bus. In this case generator $A$ obviously must be disconnected from the system in order to clear the fault, and the point of interest is how long this fault may persist without causing generators $B$, $C$, and $D$, to lose synchronism with the remainder of the system. Generator $A$ is isolated from the system by the fault while the fault persists, and is isolated by its circuit breaker when the fault is cleared. Therefore, only machines $B$, $C$, and $D$ are considered as the faulted generator, and generator $A$ is entirely eliminated from the calculations. The equivalent simplified system for this case is shown by Fig. 7, the reactances now being expressed in per cent on the combined kva. rating of generators $B$, $C$, and $D$. From this point the calculations proceed in the same manner as for the previous examples, leading to $X = 94.1$, $r_{FG} = 0.632$ and the adjusted value of $I_{FG} = 1.80$. This gives 0.53 sec. as the permissible fault duration.

If the fault had occurred on the bus, the conditions during the fault would have been the same, but after the fault the tie between the synchronizing bus through the bus of generator $A$ to the point $Q$ is interrupted. This violates the fundamental assumption that the reactance after the fault is essentially the same as before the fault, so that the curves cannot be applied with the same degree of accuracy.

## UNBALANCED FAULTS

The preceding analysis applies directly to three-phase faults. In many cases, however, investigations of unbalanced faults are of interest. The method of symmetrical components shows that from the stability standpoint an unbalanced fault may be represented by an equivalent impedance in series with the fault, the value of this impedance being a function of the negative and zero sequence impedances of the system viewed from the point of fault. These impedances may be found by reducing the negative and zero sequence network either analytically or on a calculating board.

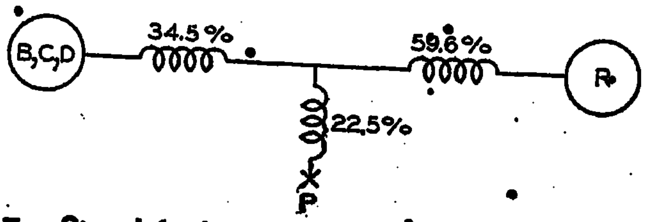

Fig. 7. Simplified equivalent of Fig. 4 for fault at *P*

## CORRECTION FACTORS

The following influences were not considered in setting up the curves of Figs. 1, 2, and 3:

1. Resistance in the connecting lines and in the fault.
2. Values of initial generator load other than normal rating.
3. Voltage regulators.
4. Systems not capable of reasonably accurate representation by two composite generators.

The correction to take these effects into account in all cases shows that the permissible fault duration is as great or greater than would be indicated if the factors were neglected. It is felt therefore that the curves of Figs. 1, 2, and 3 can be used directly without any correction factor for most work. This view is held because for most purposes the limiting cases form the basis of design. A fault of zero resistance and operation at full load give the greatest generator acceleration and therefore lowest indicated stability. Where systems do not reduce to two composite generators, the stability will be as high or higher than when they do. Voltage regulators of course increase the stability. Therefore if the curves are used directly, without correction factors, the error will be on the safe side. It is appreciated, however, that in some cases the effect of these variations on stability is of interest in system planning and operations, and approximate corrections have been set up to take care of these cases. Each of these variations has been investigated analytically, and in some cases extensive calculations were necessary to determine their effect on stability. However, since it was considered most important that the correction factors be easily applied, some liberty in accuracy was taken in formulating a method of applying the corrections. It should be understood therefore that the correction factors now to be described differ somewhat from the theoretically correct values. They are arranged approximately in the order of their importance. Correction factors affecting the value of $I_{FG}$, if used should of course be applied first.

## RESISTANCE

Resistances of the ordinary range have a minor effect on stability, with the exception of resistance in the fault circuit; that is, those branches carrying the greatest proportion of fault current. Due to the large currents in the fault circuit, a relatively small amount of resistance will result in a considerable power loss. This power loss compensates in a large measure the drop in load on the faulted generator due to drop in voltage, so that the tendency to pull out of step is minimized. Both Figs. 1 and 2 are plotted for faults at the generator terminals. Application of the location factor from Fig. 3 converts a fault at any other location to its equivalent fault at the generator terminals. For each point in Fig. 1 there is a corresponding point in Fig. 2, from which may be found the amount of power required to be dropped by the faulted generator for the equivalent fault at its terminals. If the amount of power dropped is reduced by the presence of resistance in the lines or fault, the effect would be nearly the same regardless of fault location. Hence the result may be found by reducing the equivalent amount of power dropped by the amount of the resistance losses taken by the faulted generator, and reading the corrected value of fault duration from the proper reactance curve of Fig. 2.

In the example previously considered for a fault at $M$ with $I_{FG} = 5.3$ and $X = 42$, a clearing time of 0.39 sec. is indicated by Fig. 1. The same clearing time must be indicated by Fig. 2, hence, for $X = 42$ and $t = 0.39$, it is found that 100 per cent power would have to be dropped by the generator during the fault if the fault were at its terminals. The curves have been drawn by plotting this power as per cent of the generator kw. rating, which is 85 per cent of the kva. rating. Now suppose generator $A$ and its transformer have a total resistance of 1.5 per cent on their rating; with 3.7 times full load fault current flowing, the $I^2R$ loss in the generator and transformer is $3.7^2 \times 1.5$ per cent or 20.5 per cent of the generator kva. rating, or 20.5 per cent divided by $0.85 = 24$ per cent of its kw. rating. Then instead of the 100 per cent load dropped if the generator and transformer had zero resistance, the equivalent load dropped is 100 per cent minus 24 per cent or 76 per cent. The permissible fault duration, considering the effect of resistance, is then found from Fig. 2 for $X = 42$ per cent, and power $= 76$ per cent, and indicates a permissible fault duration of 0.6 sec.

In the example given above, the resistance in only the generator branch of the equivalent circuit was considered. The power loss was then easily determined, and was all supplied by the faulted generator. If the fault is located at some point on the system where there is a number of paths in multiple for the flow of fault current, the power loss may be determined by adding the $I^2R$ loss in the various branches between the fault and the generator. The currents in the branches may be obtained by measurement of current in corresponding branches of the d-c. calculating board. They may then be squared and multiplied by the per cent resistance of the branches, and added to get the total power loss due to the fault.

If resistance in the fault itself is to be considered, the power loss in the fault must be apportioned between the faulted generator and the remaining generators. An approximate method of doing this is to multiply the total loss in the fault by the ratio $r_{FG}$, and add this value to the loss in the generator branch of the fault circuit, if this is considered. As an example, for a fault at $M$ assume $^1/_2$ per cent resistance in the arc of the fault, in addition to the resistance of the generator and transformer. With 10.4 times normal current, $10.4^2 \times 0.5$ or 54 per cent of generator kva. in power is created in the arc. This is equivalent to 54 per cent divided by 0.85 or 63.5 per cent of generator kw. rating. Multiplying by $r_{FG}$, 63.5 per cent $\times\ 0.357 = 22.5$ per cent power in the fault, taken by the faulted generator. The power dropped is 100 per cent for $X = 42$ per cent, and $t = 0.39$ sec. When 24 per cent due to generator and transformer resistance and 22.5 per cent due to fault resistance are subtracted, 53.5 per cent remains as the equivalent power dropped. This value of power dropped is seen from Fig. 2 to give a permissible clearing time in excess of 2 sec.

## Initial Generator Load

For values of initial generator load other than 100 per cent of kilowatt rating, first find the value of kilowatts dropped, corresponding to $X$ and $t$ for rated initial load. Multiply this by the ratio of initial load to full load, and read the corrected clearing time from Fig. 2, for the curve corresponding to $X$. Example: with $X = 42$ per cent, $t = 0.39$ sec., 100 per cent kw. is dropped; if the initial load had been 75 per cent instead of 100 per cent, the approximate fault duration may be read as $t = 0.61$ for kw. dropped $= 100$ per cent $\times\ 0.75 = 75$ per cent and $X = 42$ per cent.

## Voltage Regulators

Voltage regulators with a moderate rate of excitation response will give a certain amount of improvement in stability over the values given by Figs. 1, 2, and 3. The precise amount is difficult to determine, but from calculations made, assuming a rate of response sufficient to maintain constant flux in the generator field, a reasonable idea of possible improvement may be obtained. The results of these calculations when compared with the standard curves without voltage regulators show that over most of the range the improvement can be approximated by multiplying the value of $I_{FG}$ by 0.85 before entering the curves of Fig. 1.

## Different Types of Systems

The curves of Figs. 1, 2, and 3 theoretically are applicable only to systems connected essentially in star form, typified by the synchronized at the load method of connection. This is because the simplified systems which were analyzed in obtaining these curves were of the star form. However, analyses were made also of the ring connection, which represents the maximum possible deviation from the star connection, and the results of these analyses did not differ very greatly from those of the corresponding star systems. Hence, although certain variations will occur in special cases, no correction factor to take account of system connection is required for most work.

GENERAL COMMENTS

The results obtained from these curves, as is to be expected, will have the same order of accuracy as results obtained by a specific analysis of the actual system using the assumptions conventionally made to simplify the work. Further, experience and test have shown that actual systems have greater stability than the usual calculations indicate. This fact should be borne in mind when using the curves for relay settings or system design, and in general, no additional margins of safety need be allowed.

The greatest value of these curves probably lies in the facility with which they allow comparative studies of different layouts to be made. When used in this way the margins between actual and calculated values of stability are largely compensating and therefore need be of little concern except in extreme cases. Sufficient knowledge concerning load and machine characteristics, particularly those factors affecting damping, is not available at present to determine the margins with precision even as a result of the most careful and involved calculations; so that the curves presented here may be used in all cases where they apply until further data have been obtained on hitherto unevaluated factors.

# Engineering Lights the Darkness

**Shall mind or matter be fostered? In either case, engineering is lighting the path and will continue to light the way of the coming generation. This is the ninth article of the Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"**

By
A. P. GREENSFELDER President, Associated Genl. Contractors of America

DARKNESS is of two kinds: physical the absence of light, and mental the absence of knowledge. Engineering multiplies the means for the earlier relief of both varieties. To create these means is one of the functions of the engineer.

Turning night into day at first seemed sacrilegious. Other steps in scientific and engineering progress have shocked or scandalized many persons in the years that have gone, but they have come to be accepted matters of course. With the discovery of fire came the consciousness that human eyes could see in the firelight as well as in the moonlight. The history of illumination is truly romantic, the firebrand, the torch, animal oil, the candle, mineral oil lamps, gas, and successive steps in electrical illumination marking the accelerating steps in better lighting. Now, television causes no more violent agitation than a few ripples of public interest.

How has man utilized the lengthened day? First, to dispel the fears lurking in the darkness; next to light his path of travel; and then to permit recording and reading current historical events and accentuating religious ceremonies; later, to foster amusement after the hard day's hunting, tilling of the soil, or the fighting of battles; and finally, to extend the opportunities for education, commerce, and social intercourse.

The discovery of window glass changed the design of structures for man's habitation. Sunlight, by penetrating interiors, dispelled dampness and disease. The modern lighthouse and the city's show windows are wonderful combinations of glass and artificial lighting; one promotes safety at sea, and the other adds to the attractiveness of marts of trade. Speed of night transportation depends absolutely upon the engineering application of light; locomotive, vessel, and automobile headlights, signal systems, and the illumination of highways and airports are all vital necessities.

Modern buildings now go to two extremes, walls of glass and windowless walls. Conservation of daylight and complete control of illumination by exact diffusion of electric light both have their places. The "great white ways" of our cities are just signs of our times. Steam turbine power stations, hydroelectric plants, interconnected transmission lines, all bespeak engineering achievements.

INTELLIGENCE

The dispelling of mental darkness is even more vital to "life, liberty, and the pursuit of happiness" than is the conquering of physical darkness. The use of "midnight oil" has produced world leaders. Rubbing the lamp of the fabled genii produced small wonders compared to the modern miracles of man.

Whither our way? Shall we foster mind or matter? Shall we add to the mounting volumes of books or of buildings? How should they be correlated?

We talk today of over-production. We lament over-expansion of facilities for the production of goods. Then why not more homes and schools and hospitals, and better highways to make them accessible, bridges to span the gaps of time as well as space, the sowing of ideas as well as seeds?

Production is threefold: articles to be consumed, wealth in private structures, and community facilities. Engineering minds constantly are eliminating wastes of production. By steadily improving railroads, highways, and other means for carrying goods, they have brought costs of transportation to amazingly low figures compared with those of pre-railroad days. Now with even greater concentration, engineers should devote energy to reducing wastes of distribution. Engineering methods, properly utilized by business men, should be helpful in reducing the costs of merchandising just as they have been helpful in cutting costs of producing goods, power, and light. Engineers will be found ready to cooperate in solving the problems of merchandising.

Engineering analysis is forecasting the future—lighting the paths which our children will follow. Engineering talent must and will aid in directing the tendencies of the time. Perhaps more schools and fewer smoke-stacks, more fine community edifices and fewer factories, more leisure and more light, are the present needs of our people.

# Electrochemistry and Electrical Engineering

**Electrochemical and electrometallurgical industries in the United States are said to consume a considerable percentage of the total annual electric power output for the entire country. The fundamental electrochemical processes are discussed in a general way, with typical examples given for each general case.**

By
G. W. VINAL
MEMBER, A.I.E.E.

Bureau of Standards,
Washington, D. C.

IMPORTANCE of electrochemistry and electrometallurgy in the broad field of electrical engineering can be realized best when it is considered that (1) these processes furnish basic materials for manufacturing processes; (2) installed operating capacity of these industries is large and increasing yearly; (3) a vast army of workers is employed in these industries which produce outputs valued at several billions of dollars; and (4) electrochemistry and electrometallurgy present a promising field for future developments. Quoting from the 1930 annual report of the A.I.E.E. committee on electrochemistry and electrometallurgy:

> "There are many who feel that the electrical industry is more in need of increased outlet for power than of further small gains in the efficiency of electrical apparatus *per se*, and that the great body of expectant young electrical engineers must look for adequate opportunities for advancement more to the fields of utilization and electrical processes than to the conventional ones (fields) of apparatus and generation."

Before proceeding further with the discussion, definition of the term electrochemistry together with some indication of its breadth may be in order. Electrochemistry in a general way may be defined as that branch of science and technology which deals with reciprocal transformations of chemical and electrical energy. Closely related to electrochemistry is electrothermics, dealing with chemical effects produced by heat from applied electrical energy. Closely related also is electrometallurgy which deals with the application of electrochemistry or electrothermics to the extraction or treatment of metals.

The quantitative relationship between the amount of electricity passing through an electrolytic cell and the chemical effects which are produced is expressed in Faraday's laws of electrochemical action. The year 1933 marks the centenary of this great discovery by Faraday.

Electrochemical processes differ from many other applications of electric power in that a power supply of rather low voltage per unit is required, but at the same time one which is capable of delivering large currents. Because of the large currents required one of the principal problems involved is that of limiting the power loss between the power supply and the point of utilization. The provision of automatic control for electrochemical processes presents another problem with which the engineer engaged in this field is confronted; this of course is complicated also by the high current and low voltages employed. Still another problem arises in the provision of suitable insulation in apparatus for use in wet processes, especially those involving acids, caustic solutions, or fumes.

## USE OF ELECTRICITY FOR DEPOSITING METALS

One of the principal processes for depositing metals by electricity is that known as electrowinning. In this process metals or compounds are deposited from

---

Written especially for ELECTRICAL ENGINEERING, and based upon a lecture delivered during the electrochemistry and electrometallurgy session of the A.I.E.E. winter convention, New York, Jan. 28, 1932. *Not published in pamphlet form.*

solutions derived from ores or other materials using insoluble anodes.

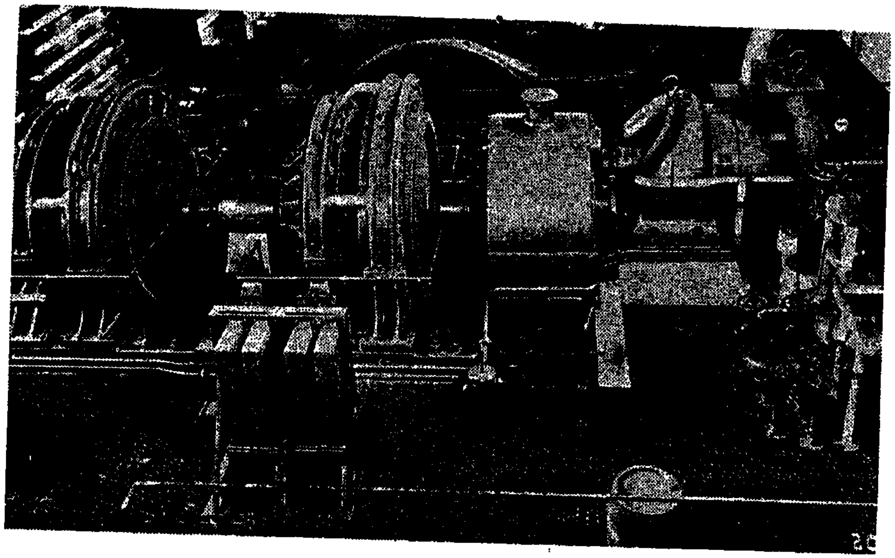
One of the more recent developments of this nature is the electrowinning of zinc. Principal advantages of this method of producing zinc are (1) the higher purity of metal produced (about 99.99 per cent pure), (2) the more complete extraction of the ore, (3) the fact lower grade concentrates are usable, and (4) materials often lost in other processes are recovered. The raw material used is a flotation concentrate of from 19 to 58 per cent zinc. This is subjected to a roasting process to eliminate the combined sulphur dioxide; the resulting calcined product then is leached with sulphuric acid, the solution purified, filtered, and finally electrolyzed by passing a direct current through it. Principal by-products of this process are, sulphuric acid and metallic cadmium. Other by-products which at the present time are lacking a market are germanium, thalium, indium, and gallium.

Besides its application to the production of zinc, the electrowinning process is applied also to the production of other metals, notably copper, and to a less extent lead, tin, nickel, cadmium, and iron.

## ELECTROREFINING OF METALS

Another deposition process which is of great importance is the electrorefining of metals. This consists essentially of the cathodic deposition of pure metal from the anodic solution of crude metal. The most important commercial process of this type is the electrorefining of copper, the estimated aggregate capacity of eight large plants in the United States being about 3,000,000,000 lb. yearly.

Copper produced from the smelter contains small percentages of other metals, such as gold and silver. To produce the exceedingly pure grade of copper required for electrical purposes and at the same time to recover the silver and gold, the smelter product is refined by electrochemical methods. In a typical large plant the operation is carried out as follows:

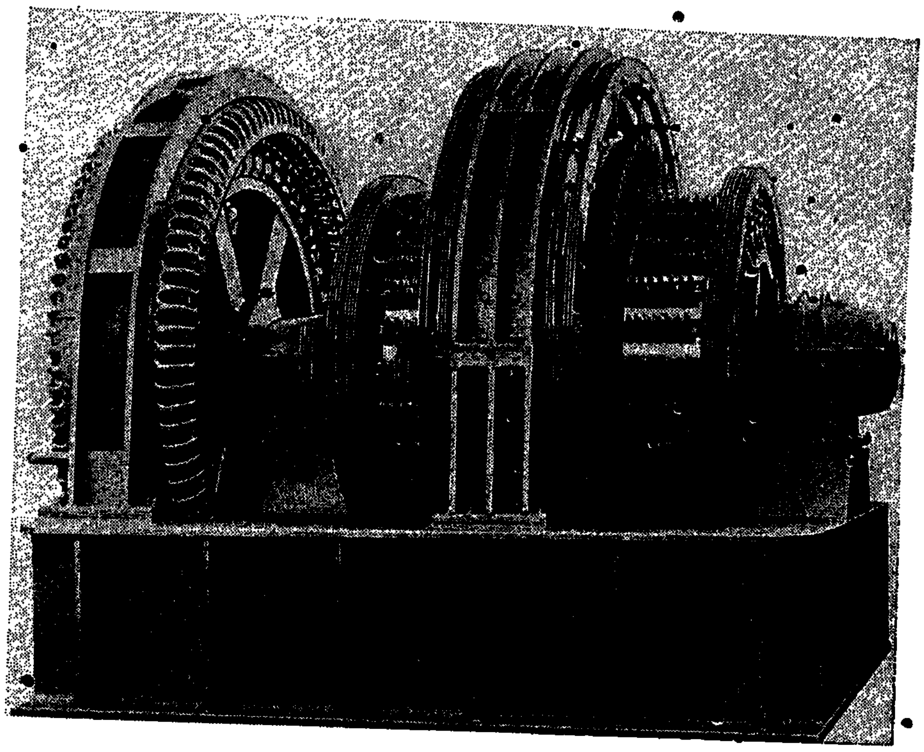


Courtesy of Westinghouse E. & M. Co.

Fig. 1. A pair of d-c. generators driven through a 10/1 reduction gear by a 3,600-r.p.m. steam turbine. Each generator is rated at 11,200 amperes, 140 volts

1. Blister copper obtained from the smelter is first melted and cast into anodes.
2. These anodes are immersed in an acid copper sulphate electrolyte; current passed through the electrolyte deposits the pure copper on the cathode.
3. Cathode copper is melted and cast into commercial shapes.

Current density used in this process (step No. 2) varies from 15 to 25 amperes per sq. ft. of cathode surface. The efficiency of the process is about 95 per cent, according to Faraday's law. Power supply for this refinery is obtained from turbine-driven generators having a total output of 12,500 kw. at 2,300 volts, 60 cycles. Power is transmitted to the tank house at this voltage where it is converted to low voltage direct current by motor-generator sets. The current passed through each tank is approximately 8,000 amperes, at a d-c. potential of 0.25 volt per tank.



Courtesy of Hanson, Van Winkle, Munning Co.

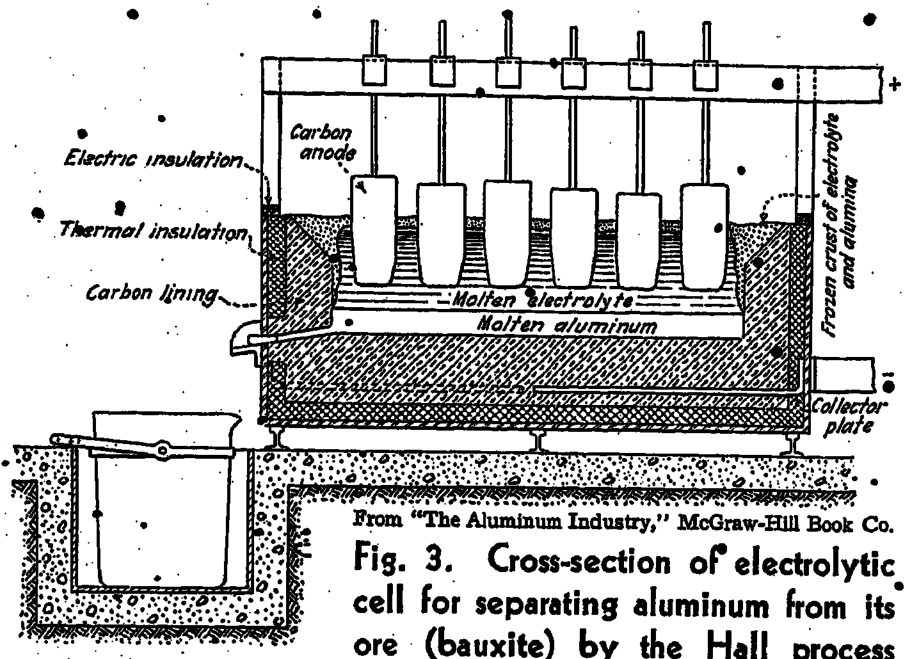
Fig. 2. Typical motor-generator set used for electroplating. Generator is rated at 10 volts, 25,000 amperes. Note commutator and multiplicity of brushes

Copper refined by the electrolytic process is characterized by its high purity, 99.98 per cent. Other metals refined electrolytically include antimony, bismuth, gold, iron, lead, nickel, silver, and tin.

Electrolytic refining of metals is a purification process which may be justified even though the per cent gain in purity may appear relatively small. The anode of crude metal may be more than 99 per cent pure but the elimination of a fractional per cent of impurities makes significant changes in physical and chemical properties. In typical cases, the refined metal is softer, has a higher electrical conductivity, is more resistant to some kinds of corrosion.

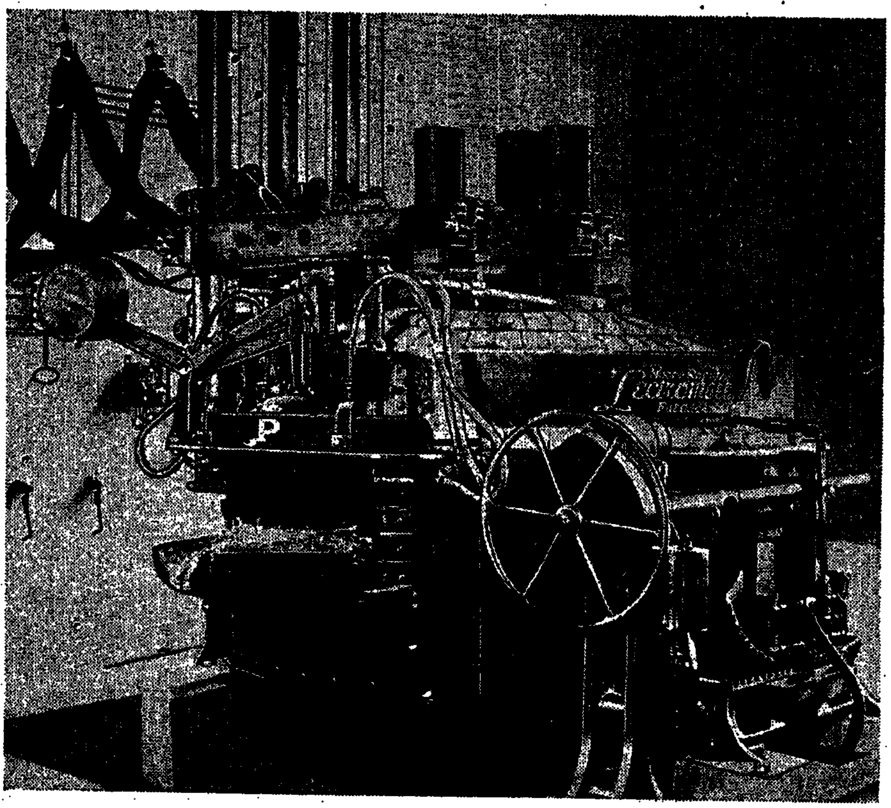
## ELECTROPLATING AND ELECTROFORMING

Electroplating is another electrodeposition process of considerable importance. In general, electroplating may be said to be the electrodeposition of an adherent coating upon an electrode for the purpose of



From "The Aluminum Industry," McGraw-Hill Book Co.

**Fig. 3. Cross-section of electrolytic cell for separating aluminum from its ore (bauxite) by the Hall process**



Courtesy of W. E. Moore & Co.

**Fig. 4. A three-phase electric arc furnace having a capacity of three tons per hour**

securing a surface with properties or dimensions differing from those of the base metal. The specific object for which plating is carried out may be ornamentation, resistance to wear or corrosion, reflecting power, increased dimensions, or other factors.

Of great interest and importance at the present time is the process of chromium plating. This was accomplished first about 70 years ago, but the past few years have witnessed an intensive development. Principal properties of chromium which are of interest in connection with its use in plating are its extreme hardness, low ductility, resistance to tarnish, and reflecting power, which is about 65 per cent (compared to 95 per cent for silver). For best results the thickness of a chromium coating is usually between 0.00002 and 0.00004 in.; thicker coatings tend to crack and peel. For best results the chromium usually is applied over a preceding metal plating, preferably either copper or nickel.

The bath used in chromium plating is chromic acid with the addition of chromium sulphate or carbonate. For the anodes, lead or iron are used; bath temperature ranges from 40 to 60 deg. cent. In this connection it may be mentioned that the "throwing" power of chromium is relatively poor. By this is meant that the ability of the metal to distribute itself evenly over an uneven cathode surface is less than that of many other metals.

In regard to the power requirements for chromium plating, a bath voltage of from 6 to 12 volts is needed (a rather high figure for plating). The current density required is from 100 to 300 amperes per sq. ft. of cathode surface. The resultant "electrolytic" efficiency is rather low which together with the valence of 6 at which chromium is deposited makes the cost of current for chromium plating rather high, in fact it is about fifteen times that for an equivalent amount of nickel plating, but less chromium generally is used.

Other electroplating processes, some of which are more or less well known, are cadmium, copper, gold, lead, nickel, silver, tin, zinc, some alloys, and even rubber. Recently some success has been attained in electroplating aluminum. Rubber, unlike the metals, is deposited at the anode and not the cathode.

Electroforming is still another type of electrodeposition; this process is used for the production or reproduction of articles. Included in this class of processes are electrotyping; reproduction of engravings, medals, and phonograph matrices; and the making of seamless tubes. The process provides an extremely accurate method of reproducing a metallic surface, and it is said that lines 0.00002 in. wide can be reproduced faithfully. Metals commonly used in these operations are copper, nickel, and chromium.

## ELECTROLYSIS OF FUSED ELECTROLYTES

Electrolysis of fused electrolytes is a process employed for the electroseparation of certain metals from ores or compounds in the fused state. One of the most common metals separated from its ore in this manner is aluminum. Although aluminum is the most widely distributed of the metals in nature, its commercial use has become possible only in recent years, largely as a result of the electrochemical process introduced by Hall. This process consists of simply passing a direct current through a molten bath of cryolite ($Na_3AlF_6$) containing dissolved aluminum oxide ($Al_2O_3$).

The electrolyzing of the molten bath is carried out in specially designed cells sometimes called electrolytic furnaces or "pots." (See Fig. 3.) For anodes carbon blocks are used, these being mounted in the tops of the cells. Aluminum in liquid form is separated by the action of the current passing through the molten bath, and is deposited in the bottom of the cell on the carbon lining which serves as the cathode. The anodes waste away gradually with the formation of carbon monoxide; the fused aluminum is protected from oxidation, however, by the fused cryolite immediately above it.

In commercial plants usually from 30 to 100 cells are connected in series. The potential required per cell is from 5 to 7 volts, the current requirement being from 8,000 to 30,000 amperes. From 10 to 12 kw-hr.

of electric energy is required per pound of aluminum produced, with a resulting operating efficiency of from 75 to 90 per cent. In this connection it should be noted that the continuity of power service in a plant producing aluminum by this method is quite essential, for if a cell becomes frozen the contents must be dug out, the material is wasted, and the cell must be relined. Purity of the aluminum produced in this manner is about 99.7 per cent.

For aluminum of higher purity, the Hoopes process for refining sometimes is used. This operation is carried on in specially designed cells also, but in this case the anode is at the bottom. Aluminum to be refined is a liquid alloy upon which is molten electrolyte, with the pure cathode aluminum at the top of the cell. The resulting product, which has a purity of better than 98.98 per cent, is relatively soft, possesses high electrical conductivity, and is resistant to corrosion.

Other metals separated from their ores or otherwise treated in the fused state by electrolysis, are magnesium, sodium, calcium, lithium, cerium, and beryllium. Beryllium is a metal lighter than aluminum, is hard and brittle, and is resistant to tarnish, but at present is not widely used.

## ELECTROLYSIS OF BRINE AND HYDROXIDE SOLUTIONS

Electrolysis of brine and hydroxide solutions is carried out in large electrolytic cells, a direct current being passed through the solutions between suitable electrodes. Some of the more common products of these processes are chlorine, hypochlorites and chlorates, caustics, hydrogen, and oxygen. Alloys of sodium also are produced in this manner in certain types of cells.

Chlorine has many uses, some of the more common being in the paper and textile industries for sanitation purposes, for the manufacture of poisonous gases, and in the formulation of synthetic organic compounds of which carbon tetrachloride is a familiar example. Hydrogen is used in the manufacture of synthetic ammonia, in the hydrogenation of oils, in atomic hydrogen welding, and in other well-known processes.

As regards the economic considerations involved in the production of gases by electrolysis, oxygen produced electrolytically must compete with that obtained by fractional distillation of liquid air. Electolytic hydrogen also competes with that obtained by other methods. There are many ways of producing hydrogen which vary greatly in cost. In most cases, however, low cost of production is offset, at least in part, by the cost of subsequent purification. Hydrogen produced by electrolysis has a purity of from 99.5 to 99.9 per cent, and this is the only method in which purification is not generally necessary. Thus it is obvious that although the cost of producing the gas may be somewhat higher by the electrolytic method, the total cost of the gas when other methods are used, including purification, is such as to make the electrolytic method attractive, particularly if there is a market for the other products of electrolysis that go with it.

In a plant recently described, units of 140 cells each are used, these being connected in series. Current and voltage requirements are respectively 2,500 amperes and 700 volts (5 volts per cell). Each unit produces 5,500 cu. ft. of hydrogen per hour.

## ELECTRIC FURNACES AND ELECTROMETALLURGY

Temperatures higher than those obtainable by combustion methods are required in the manufacture of many electrochemical and electrometallurgical products. In such cases, heating by electricity finds a ready application. In general, electric heating possesses greater flexibility of application than heat obtained from gas or solid fuel combustion. This means that heat produced from electricity usually can be developed at or adjacent to the point of use more rapidly and effectively than when fuel is used, with the further advantage that smoke, ashes, and fumes are absent.

In many electrometallurgical operations heat is applied to the material undergoing treatment in an electric furnace, of which there are various types. The electric furnace, however, is not inherently an efficient device, and special care must be exercised so that the electric energy will be applied properly.

In resistance furnaces heating is accomplished by electric current (either a-c. or d-c.) passing through some resistant material which may be either the reacting substances or a resistor from which heat is imparted to the reacting substances. One of the typical uses for the resistance furnace is in the manufacture of carborundum. In this case the current passes through a core surrounded by silica ($SiO_2$) and

**Fig. 5. (Right) Diagram of induction furnace showing magnetic field and stirring effect produced in the charge by eddy currents**

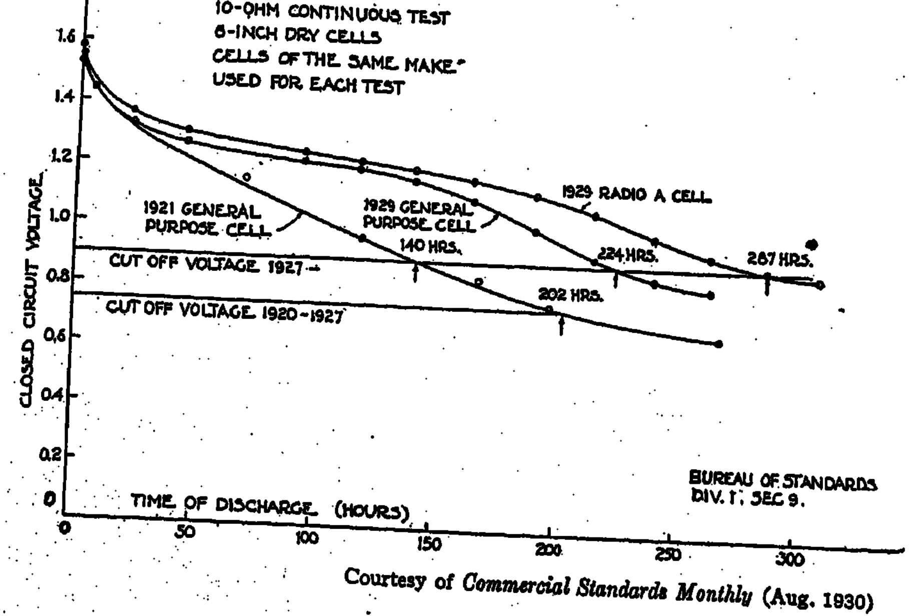
**Fig. 6. (Below) Curves illustrating improvement in commercial dry cells; output is shown for same brand of cell in 1921 and 1929**



Courtesy of *Commercial Standards Monthly* (Aug. 1930) carbon. The reaction is such that the silicon and carbon combine to form carborundum (SiC) and carbon monoxide.

Another common type of electric furnace now in use is the arc furnace which is used principally in the iron and steel and ferro-alloy industries. Arc furnaces may be subdivided into two general types: (1) that in which the arc occurs between the electrode and substance undergoing treatment; and (2) that in which the arc occurs between electrodes. Ferro alloys represent an important product of this class of electric furnace. These include not only alloys which are suitable for producing steels having certain definite properties, but also alloys such as ferro silicon and ferro manganese which are used for cleansing and deoxidizing purposes in the manufacture of such steels.

Another important kind of electric furnace is the induction type. These furnaces are used on alternating current only. The first variety of these consists essentially of a transformer with a single short-circuited turn as its low voltage winding, this turn formed by the material undergoing treatment. The second type is known as the high frequency induction furnace, in which eddy currents are induced in the charge or crucible. (See Fig. 5.) These eddy currents produce the heat. Induction furnaces have found their widest application in non-ferrous metallurgy, but recently some of the high frequency furnaces have been used for melting special alloy steels. The size of induction furnaces has been increased recently and high frequency furnaces having a capacity of four tons are now in use.

### BATTERIES

Perhaps the most common electrochemical application to the average electrical engineer is in connection with electric batteries. The well-known dry cell is a common example of primary battery and requires no further introduction. It may be of interest to note, however, that the efforts of research and testing have borne fruit in this field, as well as in others, and have resulted in the production of cells of greatly improved quality. This is brought out in Fig. 6.

Storage cells or accumulators also are familiar to the average electrical engineer and in general need no further description or explanation. They provide a portable source of power, or a dependable reserve source of power, and are applicable in cases where other power sources are lacking, as in farm-lighting plants and in submarines. The weight of storage batteries represents their principal limitation. Theoretically 12 ampere hr. per lb. per cell might be obtainable, but the present practical limitation is about half that figure.

### CONCLUSION

Treatment of the subject matter of this article necessarily has been generalized in nature. That it would be impossible in an article of this length to give any detailed treatment of a subject embracing such a wide field of activity as electrochemistry, is quite obvious. Nevertheless, electrochemical and electrometallurgical operations have been demonstrated to be a fruitful field for the application and utilization of electric power. For this reason alone the subject should be of interest to electrical engineers in general, and especially to the great body of expectant young engineers. Development of new materials and processes, however, based upon the utilization of this power is a field requiring talent of high order; but at the same time it is one which should prove extremely attractive to men of electrical training who can and will superpose upon that training a knowledge of the fundamentals of chemistry.

# Heart Injury From Electric Shock

**Experiments and observations show that the heart is especially susceptible to injury from electric shock. Using experimental animals, measurements of heart currents showed that about 10 per cent of the total "shock" current actually flowed through that organ.**

By
W. B. KOUWENHOVEN
MEMBER A.I.E.E.

NON-MEMBER

O. R. LANGWORTHY
NON-MEMBER

All of
The Johns Hopkins
University, Baltimore

STUDIES of the effects of electric shock upon rats indicated that the injury in most cases was confined to that portion of the body which was traversed by the current. (A.I.E.E. JL., V. 49, Jan. 1930, p. 25–9; A.I.E.E. TRANS., v. 49, 1930, p. 381–94 and v. 50, 1931, p. 1165–70; *Elec. Jl.*, v. 28, 1931, p. 472.) Accordingly a series of experiments was instigated to determine the effect upon the heart, since this organ is believed to be especially susceptible to injury from this source. As the extent of the injury is believed to be proportional to the amount of current flowing, experiments were directed toward determining the actual current flowing

---

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

through the heart when contact with a circuit was made at various parts of the body.

Because the ventricles of a dog's heart are readily thrown into a permanent state of fibrillation by the application of a relatively weak current, as is the case with man, dogs completely anaesthetized with morphia and ether were used in the investigation. By ventricular fibrillation is meant the failure of the ventricles of the heart to beat with a coördinated rhythm; under this condition all individual muscle fibers of the heart contract asynchronously and accordingly no blood is circulated by that organ.

## MEASURING THE HEART CURRENTS

Many interesting features were involved in measuring the current through the heart, but it was somewhat simplified by the fact that as a source an ordinary 60-cycle a-c. circuit was used. After some preliminary experiments, it was decided to measure the current by means of a ring or through type current transformer with the heart itself forming the primary conductor. If made small enough, a device of this kind could be introduced into the chest and surround the heart without seriously disturbing natural conditions. For the cores of these transformers the highest quality magnetic material was used. (The authors wish to take this opportunity to thank the Bell Telephone Laboratories, Inc., and the Westinghouse Electric and Manufacturing Company for their kindness in furnishing the cores.) These cores were ring shaped and had approximately a square cross-section with an area of 0.01 sq. in. These transformers were made up in various sizes from $^5/_8$ in. to 3 in. in diameter, for use with different sizes of hearts as found in different animals.

Each transformer core was thoroughly insulated with varnish, after which the secondary windings, consisting of No. 36 B&S gage silk-covered wire, were wound on by hand, great care being exercised to wind closely and uniformly. Each transformer core was wound with a whole number of layers, with the result of course that different transformers had different numbers of turns, these varying from 1,500 to 2,500. This introduced no difficulty, however, as each transformer was calibrated separately.

In making measurements the terminals of the transformer secondary winding were connected across a potentiometer type rheostat, and the desired portion of potential drop fed into a vacuum tube amplifier; the output of this amplifier was a measure of the current flowing through the heart. Complete details of this electrical equipment are published elsewhere (*Rev. Sci. Instr.*, v. 2, p. 541, 1931).

Operation of these transformers was carefully checked using a conducting bath of sodium chloride solution as the primary or central conductor; the bath was of such dimensions as to insure uniform current density at its center. These tests showed that with the small currents used, the transformer secondary currents in all cases were proportional to the currents actually flowing through the area enclosed by the ring. Therefore, subsequent measurements obtained with the ring enclosing the heart gave direct indications of the amount of current flowing through that organ.

## INSERTION OF THE TRANSFORMER

The heart is located in the thorax and is enclosed in a membranous sack called a pericardium; the organ lies free in this sack, its only permanent connection being the great blood vessels at its base. To insert the transformer, the thorax was opened under artificial respiration and the pericardium freed from its attachment to the diaphragm; the transformer then was passed over the apex until it fit snugly about the mid-region of the ventricles where it was held in place by ligatures passing through the pericardium. After the transformer was in place the pericardium was sewed closely to its original attachment on the diaphragm, after which the chest was closed, except for a small opening needed to carry out the transformer secondary leads. By closing the chest after insertion of the transformer and maintaining rhythmic mechanical inflation and deflation of the lungs physiological conditions were preserved as carefully as possible. The transformer secondary leads then were connected to the current measuring apparatus, and the electrodes were applied to various parts of the animal's body. The electrode circuit was arranged so that the current could be adjusted as desired.

## RESULTS

When the current pathway was from the head to the lower extremities, that is, parallel to the axis of the trunk, from 9 to 10 per cent of the current flowing through the body was found to pass through the heart. A slightly greater percentage of the total current was found to flow through the heart when it entered at the right fore-leg than when it entered at the left fore-leg.

In cases where the current entered at one fore-leg and passed out at the other, the experiments showed that only about 3 per cent of the total current passed through the heart. In these tests the current flow was across the body, and accordingly the transformers were attached to the right side of the heart. No current could be detected flowing through the heart when the current path was from hind-leg to hind-leg. Current distribution throughout the animal's body was found to remain substantially constant for a full half hour after death.

Current required to initiate fibrillation in the heart also was studied in several cases using a 5-sec. shock for each test. The amount of current necessary to produce this condition was found to vary considerably among individual animals as would be expected; the maximum, minimum, and average values observed were, respectively, 15, 6, and 9 milliamperes.

In order to check the accuracy of the results found for different current pathways, several tests were made to determine the amount of current that must be applied at the surface of the body to produce fibrillation, without the ring transformers in place.

Results of these experiments confirmed earlier findings; therefore, only one will be mentioned. In this case, a current of 90 milliamperes, entering at the right fore-leg and leaving at the lower extremities of the animal's body, was required to set the heart in fibrillation. With the current flowing between the animal's two fore-legs, 243 milliamperes were required to produce the same condition.

From the results of these experiments it is evident that a much greater proportion of total current flowing through the body will pass through the heart when the current pathway is from either hand to either foot than when it is from hand to hand. The finding that more current flows through the heart when the current path is from the right side to lower extremities than is the case when the current enters the body at the left side, confirms earlier experimental work with rats.

The authors wish to take this opportunity to acknowledge their appreciation to the committee on physiology of the Conference on Electric Shock for providing funds for this work.

# A Review of European Railway Electrification

**The development, present status, and future plans of railway electrification in western Europe were studied by the authors during the spring of 1931 on an inspection tour of the more important systems. General findings and part of the data secured are presented here.**

DURING the past 30 years in Europe, as in America, heavy electric traction has evolved from short installations on sections of road difficult to operate with steam to the present heavy traffic high speed projects which find justification economically as well as in the increased use of existing facilities. Although as indicated in Table I the United States leads the world in aggregate miles of electrifi- on as it does in total railway mileage, less than 1 nt of the mileage in this country is electrified ent is the corresponding figure for the pean countries. Despite the present s, the electrification of 275 route miles recently and 1,042 route miles are now tion or authorized.

e European countries the standard ic traction as indicated in Table II has been adopted by governmental action; in many of the countries other traction systems also are employed to a minor degree. There are four major traction systems in Europe: the single-phase and three-phase a-c. systems, and the 750/1,500-volt and 3,000-volt d-c. systems. The single-phase a-c. systems (mostly 16.7-cycle, 15-kv.) and the d-c. systems (mostly 1,500-volt) are rapidly expanding; the three-phase (16.7-cycle 3,700-volt) system probably will be slowly extended in the present region. Countries using the a-c. and d-c. systems differ in method of power generation; the d-c. systems purchase or generate power at commercial frequency and are connected with the national power networks, often considered of vital importance in selecting a standard traction system. The a-c. systems (with the exception of Sweden) generate almost all of their power at traction frequency with transmission independent of the industrial network.

## Table II—General Means of Traction Energy Supply

| Country | Traction System Adopted | Generation |  |  | Transmission Ownership | Conversion Method* |
|---|---|---|---|---|---|---|
|  |  | Steam or Hydro | Frequency | Ownership |  |  |
| Austria | A.C. 1 ph. 16.7 cy. 15 kv. | Hydro | Traction | Railway | Railway | Transf. |
| France | D.C. 1,500 volts | Hydro | Industrial | Railway | Railway | S.C. & R. |
| Germany | A.C. 1 ph. 16.7 cyc. 15 kv. | Hyd. & St. | Traction | Ry. & Ind. | Ry. & Ind. | Transf. |
| Great Britain | D.C. 750/1,500 volts | Steam | Industrial | Ry. & Ind. | Ry. & Ind. | S.C. & R. |
| Italy | A.C. 3 ph. 3.7 kv., 16.7 cy. | Hydro | Traction | Railway | Railway | Transf. |
| ........ | D.C. 3,000 volts | Hydro | Industrial | Ry. & Ind. | Ry. & Ind. | M.G. & R. |
| Netherlands | D.C. 1,500 volts | Steam | Industrial | Gov. & Ind. | Ry. & Ind. | M.G. & R. |
| Spain | D.C. 1,500 volts | Hydro | Industrial | Industrial | Railway | S.C. |
| Sweden | A.C. 1 ph. 16.7 cy. 16 kv. | Hydro | Trac. & Ind. | Gov. & Ind. | Ry. & Ind. | M.G. |
| Switzerland | A.C. 1 ph. 16.7 cy. 15 kv. | Hydro | Traction | Railway | Railway | Transf. |

* S.C. = Synchronous converters; R. = Rectifiers; M.G. = Motor-generator units; Transf. = Transformers.

Railways using the d-c. traction system are installing mecury arc rectifiers in preference to synchronous converters or motor-generators. Rectifiers are preferred even when regeneration is important, but since it is not feasible at present to construct rectifiers to handle regeneration, this energy is dissipated in resistances. Steep gradients make regeneration attractive, but few of the countries have utilized this form of braking extensively; rheostatic braking is more commonly used, but to a limited degree. In the opinion of many of the railway administrations the form of draft gear (buffer and screw coupler) does not facilitate a locomotive safely braking the train. The installation of automatic couplers, and of air-brakes on freight equipment, is now under discussion; if carried out, automatic air and control circuits will be included in the coupler, differing from the present American type.

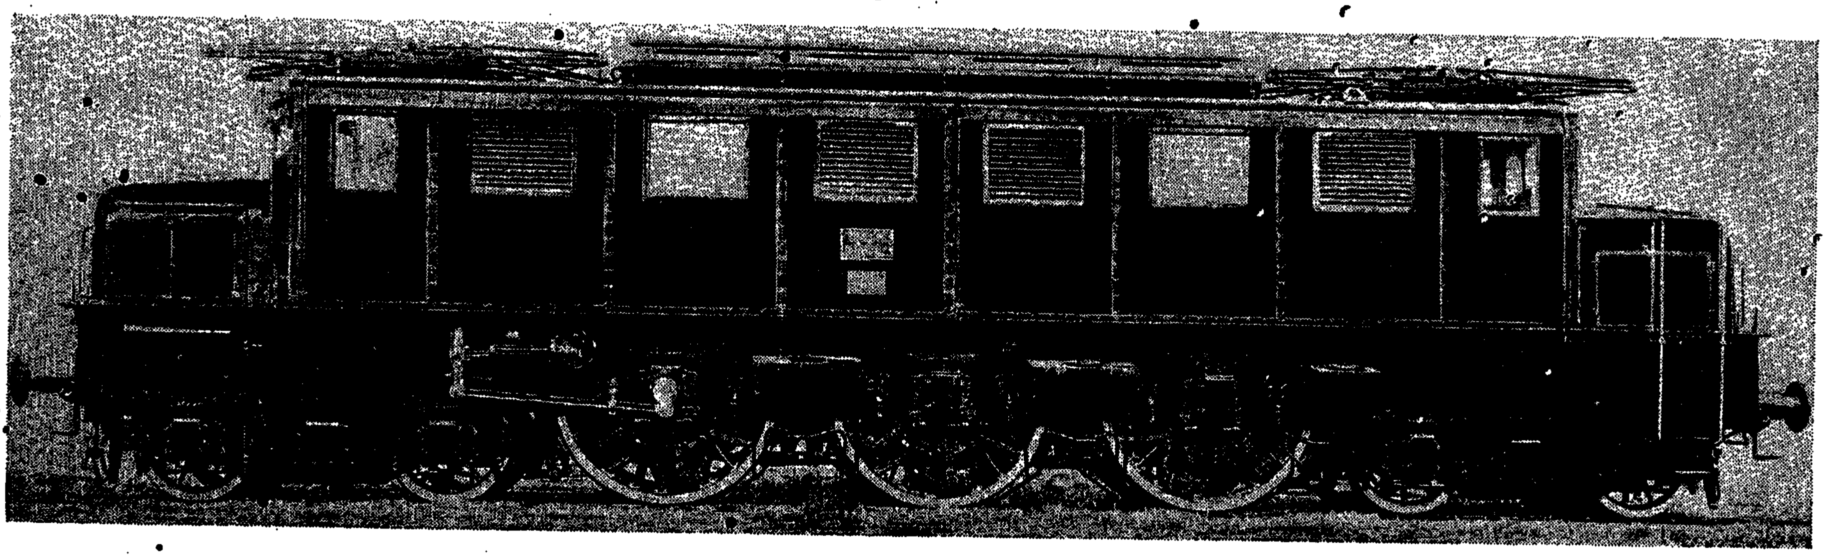
Locomotive construction generally is being standardized so that several manufacturers may supply interchangeable parts built from railway drawings. Similarly the same parts and groups are often adapted for use on various locomotive types. As in the United States, there has recently been a great improvement in the design and construction of the single-phase a-c. commutator motor, and such motors have proved extremely satisfactory. Individual axle drive locomotives generally are built for high speed express and passenger services and the side rod drive for slower services. The intervals between general overhauls vary widely in the different countries and apparently are not greatly influenced by the type of traction system.

## Table III—Contact Wire Heights

|  | Normal Ft.-In. | Minimum Ft.-In. | Maximum Ft.-In. |
|---|---|---|---|
| Austria | — | — | — |
| France | 19—8 | 15— 1 | — |
| Germany | 19—8 | 14— 9 | 21—4 |
| Great Britain | 16—0 | 13—10 | 20—0 |
| Italy | 18—1 | 14— 9 | 19—8 |
| Netherlands | 18—1 | 15— 9 | 18—5 |
| Spain | 18—1 | 13—11 | 20—0 |
| Sweden | 18—5 | 15— 9 | 20—6 |
| Switzerland | 18—1 | 15— 9 | 19—8 |
| United States | — | 15— 2 | 25—0 |

It is a common practise with motor car equipment to place all electrical apparatus, including resistance grids, in a compartment. Cleanliness, accessibility, and protection from damage are the advantages claimed at the expense of using valuable space and the difficulty of securing adequate ventilation. However, as in America, several European railways have placed this apparatus under the car body and have found this arrangement satisfactory. The use of electric train heating has made it necessary to standardize on the type of heaters and jumpers independent of the traction systems, as passenger equipment to a great extent is interchanged. In many of the countries the cars are equipped for both steam and electric heating; when trains include cars without electric heaters, boiler cars are added.

Other noticeable features in Europe are the lower insulation values and the lightness of the catenary contact systems. Contact wire height ranges are given in Table III.



Italian State Railways 3,000-volt d-c., high-speed passenger locomotive, group E-326

## FRANCE

Four of the six principal railway systems in France operate electrically about 3.5 per cent of the country's total mileage (see Table IV). The 650-volt third rail Paris suburban lines of the State railway are operated using multiple unit trains with some freight and passenger traffic handled by electric locomotives. At present further extension of the electrification does not appear likely. The Paris-Orleans railway operates electrically south from Paris to Orleans (78 miles) and Vierzon (127 miles); recently a 72-mile extension from Orleans to Tours was authorized. The 1,500-volt d-c. synchronous converter and rectifier substations are supplied from the railway's hydro stations which also exchange power with commercial power systems. Motive power consists of 10 high-speed passenger and 195 medium speed freight and passenger locomotives for freight and through passenger service, and 80 multiple-unit car sets. Suburban trains consist of 1, 2, or 3 three-car 990-hp. multiple-unit sets with control equipment mounted under the car body.

The most extensive electrification is that of the Midi railway, operating in southern France along the rugged country of the Pyrenees, with three lines into Spain. An extensive network of hydro stations and high tension lines interconnected with commercial systems supply power to 1,500-volt d-c. synchronous converter and rectifier substations. Of novel interest is the use of an inclined catenary contact system. Ten high-speed vertical drive locomotives are in service for fast international trains and six locomotives were ordered recently. There are 100 smaller medium-speed passenger and 130 freight locomotives; rheostatic braking is used on all of the freight and half of the passenger locomotives, and regenerative braking on the balance. Forty-five 700-hp. multiple-unit motor cars handle local trains.

The Paris-Lyons-Mediterranean (P.L.M.) system is electrifying a section of its line in southeastern France on one of the main routes to Italy. This installation is interesting for its use of a 1,500-volt third rail, an overhead catenary line being used only at stations. Unusually powerful locomotives are used on the mountain grades.

## SPAIN

The Spanish Northern railway has two important 1,500-volt d-c. electrifications, one in the west between Irun and Alsasua on the Paris-Madrid route and the other in the east between Barcelona and Manresa, Ripoll and Puigcerda, using multiple-unit cars and powerful passenger and freight locomotives, as well as a 3,000-volt d-c. mountain electrification on the Pajares grade in the extreme northwestern region. These lines are wide gage (66 in.). The Vascongados railway between Bilbao and San Sebastian operates an extensive meter gage system at 1,650-volts direct-current, and in western central Spain there is a meter gage 3,000-volt d-c. electrification of a road which handles principally minerals.

The electrical operation of all the trunk lines was reported by a government commission as economically justified, but because of the present financial and political conditions it will probably be some time before this extensive program, covering more than 3,500 route miles, is started.

## ITALY

The lack of coal resources and the abundance of water power in Italy early invited the use of electric traction. After the World War the Italian state railways, as part of their program to improve rail transportation, extended electrification to many trunk lines and adjacent branches. More than 10 per cent of the route mileage, handling about 20 per cent of the total traffic, is now electrically operated. The extent of the four electric traction systems is indicated in Table V. This diversified electric traction experience is of special interest to railway electrification engineers.

Originally adopted as the standard for the country, the three-phase 16.7-cycle 3,700-volt a-c. system in the mountainous northwestern section of the country is now one of the most extensive electrifications in the world. Traction power is purchased or generated at traction frequency and distributed by the railroad's network of low-frequency transmission lines to transformer substations. A satisfactory three-phase overhead contact system, consisting of one or two wires per phase, has been developed although it is complicated and expensive to construct and maintain. The locomotives, through refinements in design and construction, are very reliable in operation and low in maintenance costs. Two speeds, 16 and 32 miles per hr., are obtained on freight; and four speeds, 23, 32, 46, and 64 miles per hr. on passenger locomotives. The principal difficulties with this traction system are the unsatisfactory operation of collectors and contact line at high speeds and the impracticability of closely regulating the speed.

Although the three-phase low-frequency system was satisfactory for the mountain territory, its extension to central and southern Italy was not deemed desirable for it did not satisfy two requirements considered essential in selecting a system for extensive electrification:

1. For level lines a speed of 65 miles per hr. and higher should be reached easily and be capable of slight regulation.
2. To utilize to the best advantage the water power resources of the country, traction power should be of the same frequency as industrial power and where possible existing generating and transmission facilities should be used.

With these requirements in mind the three-phase 45-cycle (industrial frequency) and the 3,000-volt d-c. traction systems were selected in 1919 for trial installations. The three-phase 10-kv. 45-cycle system was installed in 1927–31 on the 107-mile line of 3.1 per cent maximum gradients crossing the Apennines between Rome and Sulmona. Three types of locomotives, also designed for operation on the low frequency system, are in service. Italian railway engineers consider this traction system superior to the low frequency system, as regards generation, transmission and conversion; however, locomotives are heavier, more complicated and expensive, and the contact system more costly to build and maintain. Despite the satisfactory operation it is doubtful if this system will be extended as it fails to meet the first of the above mentioned requirements.

The 3,000-volt d-c. system was installed initially in 1927–28 on the 63-mile line of 2.3 per cent maximum gradients between Foggia and Benevento in southern Italy. Electrical operation was recently extended 60 miles to Naples. Power for this line is purchased entirely from commercial power systems and converted in motor-generator and rectifier substations. A constant tension double contact wire catenary system is installed. For this line a freight and a high-speed passenger locomotive were developed and these two types thoroughly tested in service.

The high voltage d-c. system eventually will be used on the recently completed Naples-Rome direct line and now is being installed on the direct line under construction between Bologna and Florence. The present 82-mile line between Bologna and Florence, the central main route between northern and central Italy, has maximum gradients of 2.6 per cent with numerous tunnels and is a line difficult to operate with steam power. During 1921 to 1927 it was electrified with the three-phase 16.7-cycle system. Construction on the more direct line with lower gradients through the Apennines was started in 1920 involving the longest double-track tunnel (11.5 miles) in the world and reducing the route distance 21 miles. Completion is expected in 1934 and then the present three-phase line will be converted to the 3,000-volt d-c. system.

The extensive use of portable substations for the a-c. and d-c. systems is original and unique. For the 16.7-cycle system a 2,250-kva. three-phase transformer with oil switches is mounted on a special flat car of 100 tons total weight. A 2,000-kw. 3,000-volt rectifier unit is mounted on a partially enclosed car which weighs 82 tons complete with transformer and all switching apparatus. Two such rectifiers have been delivered for test and on new lines it is planned to use such units in place of some of the usual fixed stations.

### Table V—Electrified Sections of Italian State Railways

Stringing contact wire on Naples line for Italian State Railways, using 40-hp. gasoline-engine tower-car and small reel-car

Recent a-c. and d-c. locomotives have been carefully standardized. The two types of d-c. locomotives and an 80-ton type B+B branch line freight and passenger locomotive are expected to provide for all future d-c. system requirements. The same motors, contactors, resistances, compressors, gear cases, and axle bearings will be used for these three types.

The privately owned North Milan railway handles a heavy suburban traffic to the Lake District, and 75 track miles over 31 miles of route are electrically operated using the 3,000-volt d-c. system. Power is purchased and converted by rectifiers. Sixteen 720-hp. two-car multiple-unit sets and four electric locotives are in service. Since electrification, local service has been doubled and the running time reduced 35 per cent. Twin contact wires are supported by flexible strand hangers from a copper messenger.

## SWITZERLAND

Switzerland is a country of particular interest because of the early development and present intensive application of electric traction. All the through routes and most of the important local lines have been converted, leaving only secondary lines on which electrification is progressing at the rate of about 60 route miles per year.

Railway operation is beset by many difficulties; there are steep grades, many tunnels, and much single track mountain line. Coal must be imported and an assured and cheap supply is often difficult to obtain. In almost all sections of the country, however, water power is available in abundance. Electrification, therefore, has been undertaken for economic reasons, for the increased facility in handling heavy through international freight and passenger traffic, and also for national security and the further utilization of natural resources. There are two important standard gage electrified systems—the Federal railways and the Bernese Alps railway; also many electrified narrow gage adhesion and rack lines.

A special commission reported in 1914 that the electrification of certain Federal system routes was desirable economically and the single-phase 16.7-cycle 15-kv. a-c. traction system was recommended, with single-phase traction-frequency generation and transmission by railway owned generating stations and high voltage transmission lines. Plans were being made for the conversion of the St. Gothard line when the World War intervened. In 1923, because of the unemployment situation and coal difficulties, an accelerated program was adopted with approximately a 20 per cent subvention by the government, and phenomenal progress was made during the five years following.

Catenary line and structures on Swiss Federal Railways, showing bracket pull-off pole, 16-kv. insulation and wire screen highway protection

Electric locomotive design has been standardized so that interchangeable equipment is furnished by the three large electrical manufacturers, with another firm making all of the mechanical parts. In recent years the individual axle drive has been preferred for high speed passenger service, 60 per cent of all the locomotives being of this type; the side rod drive is used mainly for the slower services. One-man locomotives are used extensively in freight and local passenger services by the use of the "dead-man" controller. Two new locomotives of about 7,200 hp. recently were completed. All transformer tap changing is done on the high voltage side to avoid handling the large secondary currents with contactors. As on some other locomotives, regeneration is provided only to the extent of the locomotive weight and is intended for use to increase the safe speed when operating light down mountain grades.

The other major electrified system comprises 164 route miles operated by the Bernese Alps railway, which is owned by the Canton of Bern. This line was the first to use the present Swiss standard traction system, installing it for trial in 1910.

### AUSTRIA

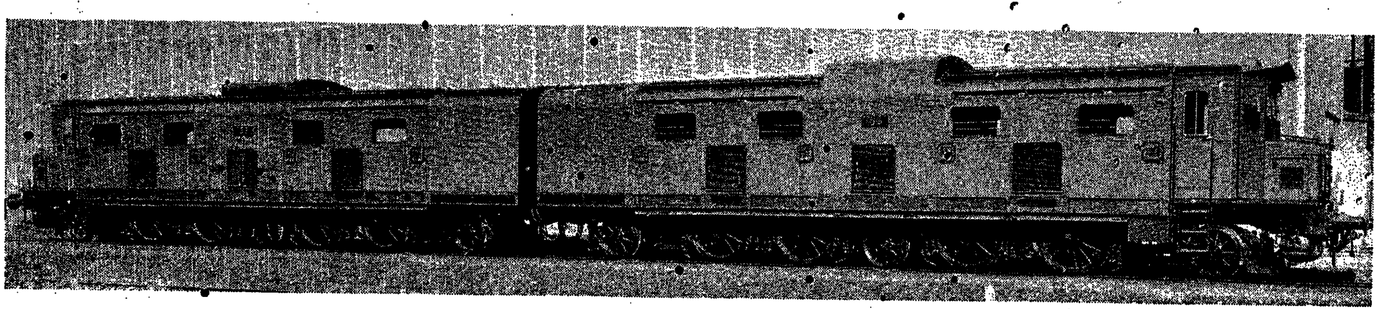
Electric traction was installed on the mountain lines of western Austria for reasons similar to those of Switzerland and to compete with paralleling international routes being electrified in other countries with a reduction in running time which would divert traffic from the Austrian lines. The same traction system (single-phase 16.7-cycle 15-kv.) as used in neighboring Germany and Switzerland was adopted, and, as in these countries, most of the power is generated and transmitted in traction form by railway-owned hydroelectric plants and transmission lines. The locomotives are side rod drive with jackshaft and individual axle drive with geared horizontal and bevel-geared vertical motors. Because of the financial conditions and the present low price of coal the further electrification of some 500 route miles has been postponed.

### GERMANY

The extensive use of electric traction in Germany began after the World War. There are four important and several smaller electrified sections of the German State railways located in widely scattered parts of the country. Three of these districts, the Bavarian, Silesian and the Central, use the single-phase 16.7-cycle, 15-kv. a-c. system adopted as the standard for trunk lines, and the Berlin district an 800-volt d-c. third-rail system for a rapid-transit suburban service. Single-phase, 15-cycle, 15-kv. power is used on a 30-route-mile electrification at Basle and 25-cycle, 6-kv. power on the 23-mile Hamburg installation.

In the Bavarian district through freight and passenger trains and heavy suburban traffic from Munich are handled electrically over a total of about 1,000 track miles on 434 miles of route, which gradually is being extended. Most of the power is purchased, using special traction-system generators and transmission lines. A total of 190 passenger, freight, and switching locomotives and 37 motor-car sets are assigned to this section. Most of the freight and some of the passenger locomotives are the side rod drive type with geared jackshaft; high-speed passenger locomotives are type 2D1 or 1D1 individual axle drive. Multiple-unit car trains consist of one or two units, each consisting of a two-motored 750-hp. steel car and three trailers. Both the air-cooled transformer and the oil circuit breaker are in a special compartment. The locomotives and motor cars have "dead-man" control for one-man operation.

The mountain road electrification between Breslau



New St. Gothard line 7,200-hp.-$1B_01\ B_01 + 1B_01B_01$ locomotive for Swiss Federal Railways, prior to installing electrical equipment

and Gorlitz in the Silesian district includes about 217 route miles and 507 track miles. Power is generated by the railway at traction frequency, utilizing a very low grade of coal. The Central district (Leipzig-Halle-Magdeburg) has a heavy traffic which is handled at high speeds over fairly level country, using locomotives and motor cars on about 118 electrified route miles and 409 track miles. Power is generated in traction form, using a peat that cannot be burned in locomotive boilers.

The Berlin suburban lines were electrified in 1924 to furnish a rapid transit service on 145 miles of route (365 miles of track) using multiple-unit car equipment. Purchased power is converted by synchronous converters and rectifiers; the rectifier installation is the largest in the world for a single system. Contrary to common practise the anode and rectifier tank are at ground potential and the third rail is negative.

A meter gage, 12-mile 1,650-volt, d-c. railway, the Zugspitze, was recently completed to the highest mountain peak in Germany, using an adhesion, rack and aerial line. Glass-tube rectifiers convert three-phase 50-cycle power for traction purposes.

German locomotive design and construction also are standardized. Air blast transformers are used and now the electrical manufacturers are perfecting an air blast circuit breaker so that no oil will be required on the locomotive or motor car.

## SWEDEN

Sweden is rich in water power resources, but entirely lacking in coal deposits, hence careful consideration has been given to the advantages of electric traction. The State railway system, operating most of the trunk lines and about 40 per cent of the total mileage, now has more than 14 per cent of the route mileage and 25 per cent of the traffic electrically operated. A very extensive program of electrification extension is under way and scheduled for completion in 1934.

One of the first electric installations (1912–1922) is the Northern Ore line. This 287-mile line, which goes 170 miles north of the Arctic Circle 's therefore the most northerly electrified rail- in the world; handles heavy ore traffic from on mines at Gellivare and Kiruna east to Lulea e Gulf of Bothnia and west to Narvik in Norway he Atlantic Ocean. The 15-cycle 15-kv. single- e a-c. traction system, with high voltage single-phase transmission to track-side substations from a central mixed-frequency hydroelectric plant, was adopted.

Four-car multiple unit suburban train at Munich. There is one motor car with three trailers

After the war electrical operation was considered for the Stockholm to Gothenburg trunk line and the government again studied the matter of a traction system, concluding that the single-phase 16.7-cycle, 16-kv. a-c. system would be satisfactory. Careful study of the location of a negative return wire on the catenary structure and the use of booster transformers for minimum communication circuit interference satisfied the government communications board, which cabled their circuits or removed them from the railroad right-of-way. Traction power was obtained from the existing commercial power stations and transmission networks by installing frequency-converter substations about 58 miles apart without paralleling traction-frequency feeder or transmission lines.

A geared jackshaft side rod drive type 1C1 locomotive, identical for both freight and passenger services except in gear ratio, was adopted as standard. These locomotives handle a 550-ton passenger train or 990-ton freight train over the profile of 1 per cent maximum gradients. Sweden is now the only important country that has not at least partially adopted the individual axle drive, and is the only country extensively using a wooden locomotive cab.

In 1931 electrification of the 392-mile trunk line south from Stockholm to the ferry terminals at Malmo and Tralleborg, and three branches totaling 177 miles which connect this line with the Gothenburg electrification, was authorized at an estimated gross cost of about $17,000,000. Complete electrical operation is to be started in 1934. Commercial power will be purchased from existing power systems without the construction of additional high tension lines, and six motor-generator frequency-converter substations having an average spacing of 70 miles will supply power to the contact line. As the branch lines do not require additional substations there is an average of 90 route miles per substation. Seventy-five standard freight and passenger locomotives, 21 switching and 8 battery-trolley locomotives have been ordered and are now under construction for this electrification.

A comparison of estimated operating costs shows a very favorable annual saving above all fixed charges with electric operation. The eventual electrification of about 600 route miles of other trunk lines is contemplated, which will then complete the electrification of the government system's main routes.

At Sundsvall a privately owned railway is completing a 12-mile electrification using the 1,500-volt d-c. system and 8 motor-car and trailer sets. Many of the smaller privately owned short railways throughout the country have adopted with great success diesel-electric cars on branch lines of light traffic.

### DENMARK

The Danish state railways have under consideration the electrification of the heavier traffic suburban lines in the vicinity of Copenhagen, to increase the capacity of the present congested trackage through that city, and to effect economies in operation. Electrical operation of about 23 miles of route using multiple-unit equipment is contemplated, and a d-c. overhead contact system at 1,500 or 3,000 volts was studied.

Gasoline-engine passenger cars, some direct drive and others electric drive, and diesel-electric locomotives are used extensively on branch lines and on the main routes. Two type 2D2 900-hp. diesel-electric locomotives were recently delivered to the railway; these locomotives are designed to handle a 275-ton train at 46 miles per hr. and have an operating range of 370 miles, thereby enabling the longest round trip to be made without refueling.

### THE NETHERLANDS

Approximately three-quarters of the country's railway mileage is operated by the Netherlands railway, which has about 7 per cent of its route now under electrical operation for passenger service, using multiple-unit cars. In May 1931, the lines from Amsterdam to Uitgeest and Alkmaar, and Velsen to Uitgeest were converted to electrical operation, in addition to the Amsterdam-The Hague-Rotterdam line and branches which have been electrically operated since 1927. Purchased power is used entirely, and converted to 1,500-volts direct current by automatic rectifier substations which are supervisory controlled from adjacent interlocking towers. The one motor-generator substation is manually operated. On the earlier installation multi-unit substations were spaced 6.9 to 10.2 miles apart with intermediate sectionalizing tie stations. The recent installation consists of single-unit substations spaced about 4 miles apart. The contact system is of the twin contact wire type, and is unique for the suspension of both contact wires from the same hanger.

Rolling stock of the most modern type is used, and eight different 760-hp. motor or trailer cars of various passenger classes are combined as desired to make up trains of from 2 to 10 cars. The latest motor cars have roller-axle and motor armature bearings. As the railway faces severe competition from motor buses, other heavy traffic passenger lines, as from Amsterdam to Utrecht, probably will be electrified. The

electrical operation of freight and through international passenger trains is not planned at present.

## GREAT BRITAIN

The three outstanding recent electric traction developments are:

1. The Ministry of Transport report on main line railway electrification (1931) commonly referred to as the "Weir Report."
2. Extension of the Southern Railway's third-rail electrification to Brighton on the Channel coast.
3. Inauguration of electric service between Manchester and Altrincham using 1,500-volt d-c. multiple-unit equipment.

With the exception of the Newport-Shildon 1,500-volt d-c. line all of the electrification is suburban and much of the mileage is in the London district; other installations are located at Manchester, Liverpool, Lancaster, Newcastle-on-Tyne, and Newport. During the past decade, with the formation of the national grid system for electric power transmission and distribution, the government has viewed with increasing interest the possibility of using electric traction on the railroads and various committees have reported on this subject. The Pringle (1927) report definitely recommended the use of direct-current, either 750-volt third-rail or 1,500-volt overhead, with the possibility of considering 3,000 volts for special conditions. The Weir report (March 1931) recommended that if the railroads are to be electrified practically all of the lines must be converted to avoid the uneconomical conditions incidental to dual steam and electric operation. This stupendous project, covering almost 20,000 route miles, would be spread over a period of 20 years, the total gross expenditure being estimated at $1,964,000,000.

The Southern Railway's London suburban electrification, the largest of its kind in the world, has 300 route and 800 track miles electrically operated. With the completion of the Brighton electrification at the end of 1932 the electric system will include 965 track miles on 350 miles of route; this is about 18 per cent of the company's mileage. The 650-volt d-c. third-rail distribution system is supplied by 52 synchronous converter substations converting from 25 cycles. Eighteen supervisory-controlled single-unit rectifier substations are to supply power for the Brighton extension from the 50-cycle national grid sytem. Multiple-unit equipment is used entirely, in trains of from 2 to 9 cars. The standard motor unit consists of two 550-hp. motor cars and an intermediate trailer; a few two-car motor units were purchased recently. Two-car trailer units are used between motor units. All control apparatus including resistance grids is placed in a compartment of the motor car. There are a total of 1,948 cars of which 832 are motorized; most of these have been converted from former steam equipment.

The Manchester, South Junction, and Altrincham railway is the first electrification to follow the 1927 committee's recommendation of 1,500-volt direct current. Electric service with multiple-unit equipment was inaugurated in May 1931. The line is 8.7 miles long (28 track miles) and was electrified to meet bus competition more effectively. Purchased power is converted by synchronous converters and a rectifier. The catenary contact system consists of a copper messenger, stranded auxiliary, and a 318,000 cir. mil contact wire, totaling 1,000,000 cir. mils in conductivity. Three-car units consisting of a motor car, trailer, and control trailer are used; trains may be made up of 1, 2, or 3 such units. Motor cars, weighing 63 tons, have four 330-hp. motors and a maximum safe speed of 70 miles per hr.; trailer cars weigh 35 tons.

European railways are apparently well satisfied that the operating economies, increased speed, cleanliness, increased track capacity, and use of natural resources such as water power or low grades of coal, are advantages that justify further extension of railway electrification even during a severe economic crisis. The execution of such projects during times of depression has been of material assistance in alleviating unemployment in several of the countries. Perhaps America could profitably follow such an example.

---

# Impulse Testing of Large Transformers

**Impulse voltage tests provide valuable information concerning a transformer's ability to withstand high voltage surges in service. By making such tests with the transformers excited, power current will flow into any faults which occur, thus providing unmistakable evidence regarding the nature and location of such faults.**

By
F. D. NEWBURY
FELLOW A.I.E.E.

Westinghouse Elec. & Mfg.
Co., East Pittsburgh, Pa.

PRESENT standard dielectric tests at low frequency no longer are considered to give a satisfactory measure of the real strength of transformer insulation. This fact was emphasized during the recent A.I.E.E. winter convention, at which the question of impulse testing of large power transformers received considerable attention. In general, engineers who discussed the question at that time agree that impulse tests would afford valuable information concerning the ability of transformers to withstand surges encountered in service, and that steps should be taken to establish a standard test pro-

---

Prepared especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

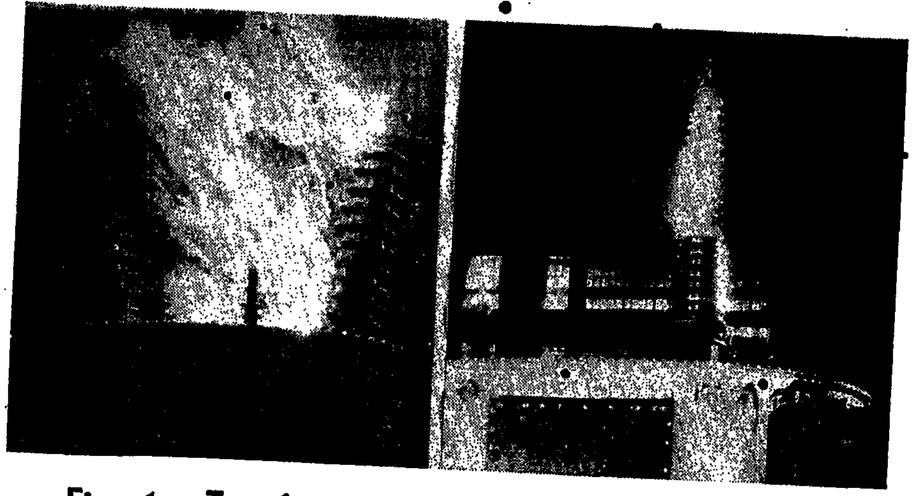

**Fig. 1. Transformer bushing flashovers (left) with superposed surge and normal-frequency voltages; (right) with surge voltage only applied**

cedure for impulse testing. It was suggested further that the A.I.E.E. electrical machinery committee might undertake this task.

Development of a suitable method of impulse testing for transformers involves several problems if such methods can be considered safe and reliable measures of insulation strength. One of the principal difficulties encountered is the detection of insulation failures when they occur, and some question exists as to whether a method less thorough than complete disassembly of the transformer insulation is adequate for this purpose. The problem of detecting insulation failure is solved, however, by the simultaneous application of surge voltage and normal frequency exciting voltage, so that failure is accompanied by the flow of power current.

When an insulation failure occurs during a normal-frequency dielectric test, the fact that failure has occurred is demonstrated by the obvious effects of the power current that flows into the fault. In the surge test as ordinarily made, the energy discharged by the surge generator may be insufficient to produce unquestionable physical effects, if the failure occurs within the transformer winding. If on the other hand the surge be applied with the transformer excited, as in normal service, an insulation failure caused by the surge voltage would be followed by power current; the fact of such failure would be as patent and as unmistakable as in the case of a failure in service, or of a failure during a normal-frequency dielectric test. (See Fig. 1.)

Simultaneous application of surge and power voltages has been recognized generally as the satisfactory solution of this problem, and this combination test was carried out successfully on distribution transformers two years ago. In applying the method to high voltage transformers, however, additional difficulties are encountered in obtaining a simple and practical method of preventing the transformer voltage from injuring the surge testing equipment. This latter problem has been solved by F. J. Vogel of the Westinghouse company by an ingenious application of the Torok tube, an arc rupturing device operating on the deion principle.

In Fig. 2 is shown a circuit developed for testing high voltage transformers by the method just outlined and employing a deion gap as mentioned. In this diagram, the surge generator is tripped by gaps *3* and *4*, and these in turn by the voltage from the condenser $C_t$. If a positive surge is required from the generator, a negative voltage is required from $C_t$. Gap *3* is set so that the voltage of $C_1$ is not quite sufficient to cause breakdown; gap *4* is set at a lower voltage than gap *3*. A small negative voltage from the tripping condenser trips gaps *3* and *4* in succession, gaps *1* and *2* insuring the synchronizing of the surge with the 60-cycle voltage. Voltage at gap *1* is a maximum when voltage from the tripping transformer is at maximum positive polarity at the crest of the wave. Gap *2* is set high enough only to with-

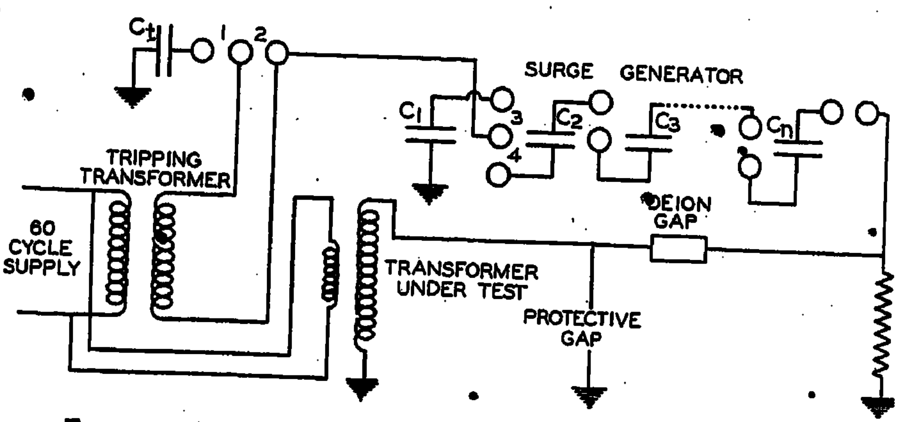

**Fig. 2. Equipment for testing transformers with surges applied at crest of exciting voltage wave**

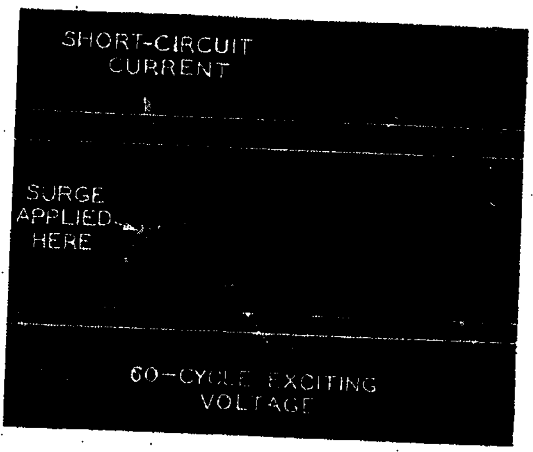
Application of this method to high voltage transformers was made possible by use of the deion gap to protect the surge generator from the transformer voltage

**Fig. 3. Oscillogram of transformer bushing flashover showing application of surge and beginning of short-circuit current at crest of exciting voltage wave**



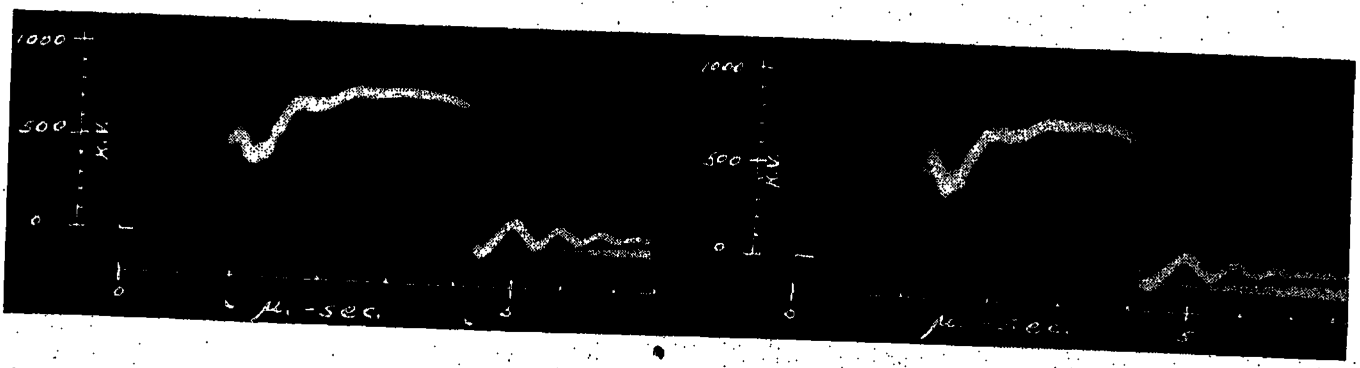


**Fig. 4. Addition of deion gap to circuit does not affect surge voltage; (left) surge voltage wave with gap; (right) without gap.**

For this test, oscillograph was connected between surge generator and deion gap stand the 60-cycle voltage. If gap *1* is set so that it will just break down when the 60-cycle voltage is applied, the crest of the wave will be picked off automatically.

Operation of the circuit described is illustrated by Fig. 3, which shows an oscillogram taken during a bushing flashover on a 138-kv. transformer. Application of the surge and the start of the short circuit are indicated clearly. Timing of the surge is arranged so that it is imposed at the crest of the 60-cycle voltage wave. Experience has shown that with the surge and power voltages synchronized in this manner, power current will follow in every case in which the transformer insulation fails to withstand the surge voltage. It should be noted further that the use of the deion gap as shown in Fig. 2 does not affect the surge voltage. This is demonstrated by Fig. 4, which shows oscillograms of surge voltage during bushing flashovers with and without such a gap in the circuit. It may be noted that the voltage and time-lag of the flashovers are practically the same in both cases.

This development is particularly timely considering the discussion on the subject at the recent A.I.E.E. winter convention mentioned in the beginning of this article. Availability of this test procedure opens up the possibility of an entirely new basis for establishing the sufficiency of transformer insulation. Furthermore, it brings within the range of practical discussion the project of standardizing the test procedure, test wave, and voltage values for surge testing.

# Design Features of Potentiometers

**Fully nine-tenths of all potentiometers now being built are said to find their way into industrial plants. Low-resistance instruments are shown to possess many advantages over those with high resistance.**

By
**I. MELVILLE STEIN**
MEMBER A.I.E.E.

Leeds & Northrup Co.,
Philadelphia, Pa.

POGGENDORF'S "compensation" circuit, from which all potentiometer circuits have been developed, was brought out about the middle of the nineteenth century. This original circuit was devised for measuring the open circuit e.m.f. of primary cells; in all precise potentiometers of today, the open circuit voltage of a primary cell is used for standardizing the potentiometer current. As practically all of the primary cells used with potentiometers develop an open circuit e.m.f. a little in excess of 1 volt, most potentiometers have been designed to have ranges of approximately 1.5 or 2.0 volts. An important exception arises in the case of potentiometers designed for precise measurements of temperature with thermocouples. Such instruments usually are designed to have a range of approximately 0.1 or 0.01 volt.

Potentiometers have been designed with a range as high as 15 or 16 volts, but usually such a high range is not required. It is preferable not to connect high voltage directly to the potentiometer, but to extend the range of a 1.5- or 2-volt potentiometer to any desired value by means of a voltage divider, commonly known as a "volt-box." It is usual practise to equip potentiometers with range-changing devices, so that two or three ranges are available in one instrument.

## POTENTIOMETER RESISTANCE

No direct relationship exists between the potentiometer range and its resistance. It is true that all low range potentiometers for use with thermocouples are designed to have low resistance, as a high resistance in the potentiometer circuit would interfere with obtaining the desired sensitivity; but it does not follow that a high range instrument should have a high resistance. While a high resistance may be used in a high range potentiometer, a low-resistance potentiometer is preferable for the following reasons:

1. Inherently, a low-resistance potentiometer makes possible a higher sensitivity than can be obtained with a high-resistance instrument.
2. Errors due to current leakage between the potentiometer parts are much smaller in a low-resistance instrument.
3. Low-resistance coils are more stable than high-resistance coils.
4. Proper galvanometer damping is easy to obtain with a low-resistance potentiometer and difficult to obtain with a high-resistance instrument.
5. In a low-resistance potentiometer at least one-tenth of the range may be covered with a slide wire; this results in a simple and inexpensive construction.
6. For the same sensitivity, a low-resistance potentiometer permits using a higher resistance in the volt-box.

Distinct advantages result from the use of low resistance even in a high range potentiometer where the high-resistance instrument is not barred out definitely because of lack of sensitivity. For in-

---

Based upon "Design of Potentiometers" (No. 31-118) presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1931.

stance in measuring current by measuring the potential drop across a current shunt, if shunts of equal energy dissipating capacity are used, the low-resistance potentiometer permits the use of a more simple and rugged form of galvanometer; if galvanometers of the same sensitivity are used, then the energy dissipating capacity, and consequently the size and cost of the current shunt, may be reduced when working with the low-resistance potentiometer.

Lower operating current represents the only advantage which may be claimed for the high-resistance potentiometer; this advantage, however, can be shown to be more apparent than real. In the days when a 50- or 60- ampere-hour storage cell was a fairly expensive item and when it was necessary to reset all of the potentiometer dials in order to check the potentiometer current against the standard cell, a potentiometer requiring much less current than 0.01 or 0.02 ampere probably had a real advantage. Now that fairly large storage cells are available at small cost and potentiometers are designed so that the current may be checked instantly without resetting the dials, an instrument requiring as much as 0.01 or 0.02 ampere is at no disadvantage, but on the contrary is at an advantage because with the higher current any small leakage currents produce much smaller errors. In Fig. 1 is shown the extremely small drift in current for a typical potentiometer requiring 0.02 ampere supplied from a storage cell of 60-ampere-hour capacity.

Reference already has been made to the possibility of using a slide wire for the lower part of the range of a low-resistance potentiometer. As a matter of fact, however, it is not at all essential and almost all of the low-resistance potentiometers designed for making precise temperature measurements with thermocouples are equipped with dial switches throughout.

A low-range, low-resistance, dial-type potentiometer recently proposed is shown schematically in Fig. 2. This instrument has a low total resistance (less than 15 ohms and substantially constant) and the circuit arrangement is such that errors due to resistance variation and parasitic e.m.f.'s at the switch contacts are reduced to less than one step on the fifth dial.

While the instrument shown in Fig. 2 has six dials, not more than five are intended to be used at one time, as the use of all six would assume a higher accuracy in the standard cell and in the resistance adjustments than is obtainable in ordinary practise. The sixth dial is included as the equivalent of a range-changing device, that is, when using dials I to V inclusive, the range is approximately 0.1 volt; when using dials II to VI inclusive, it is about 0.01 volt.

## DEFLECTION POTENTIOMETERS

In the deflection potentiometer, the principal part of the potential being measured is balanced against a known potential just as is done in an ordinary null potentiometer; the remaining small portion of the unknown potential is read from the deflection of a calibrated galvanometer. The fundamental requirement in the design of a deflection potentiometer is that, for all connections and adjustments of the instrument, there must be no appreciable change in the galvanometer circuit resistance.

Aside from its use in photometric measurements, the most important application of the deflection potentiometer is in checking large numbers of portable indicating instruments. In discussing this latter problem, Dr. H. B. Brooks, of the United States Bureau of Standards, points out that null potentiometers are the most accurate for the purpose, but require too much time to use. Doctor Brooks further shows that long scale laboratory standard deflecting instruments, while faster in operation, are not sufficiently accurate for the purpose. He concludes that "the need unquestionably exists for a type of instrument for current and voltage measurements which will have properties intermediate between those of the ordinary deflection instrument and the elaborate potentiometer."

It is interesting to note that although the deflection potentiometer does provide an instrument intermediate in accuracy between the null potentiometer and the laboratory standard deflection instruments, it is not intermediate in speed of operation. It is faster than either of the other two. In the deflection potentiometer, the galvanometer pointer is short and light and this results in a short period. Furthermore, it is unnecessary to take the time to estimate tenths of a division. Because the position of the pointer does not change very much and need not be observed more closely than to one

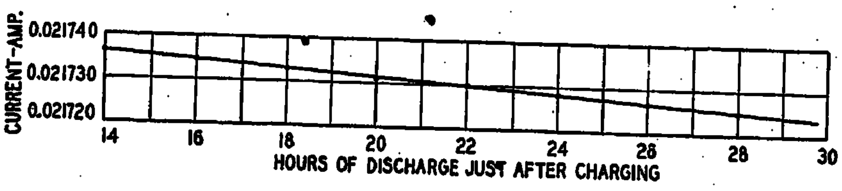

**Fig. 1. Current drift for a typical 100-ohm potentiometer supplied from a lead storage cell**

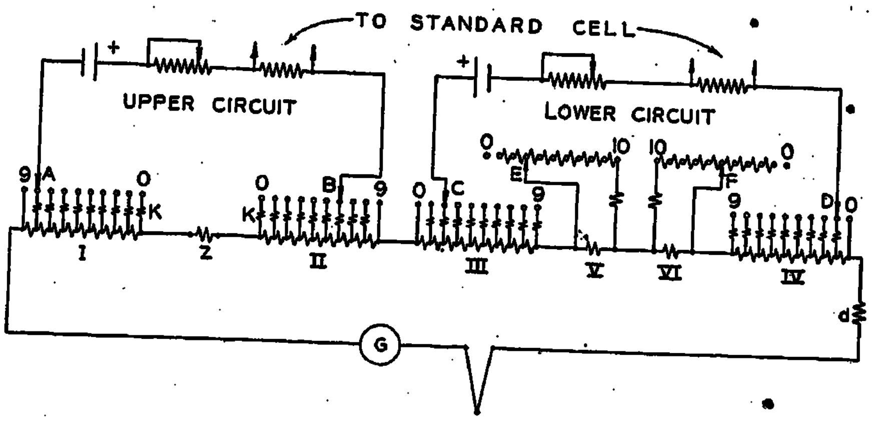

**Fig. 2. Schematic diagram of a recently proposed low-resistance potentiometer with two ranges (0.1 and 0.01 volt, respectively) and five dials**

This instrument is especially adapted for thermocouple measurements. Upper and lower circuits are connected so as to utilize the difference of the two potentials, thus avoiding the necessity of reducing both potentials to zero to obtain a zero reading on the potentiometer division, it is unnecessary for the operator to change his position frequently in order to remain in line with the pointer. This latter precaution is essential in reading laboratory standard deflection instruments to avoid parallax errors.

In conclusion it may be of interest to point out that the use of potentiometers in industrial plants has increased remarkably in recent years. A fair estimate indicates that nine-tenths of the potentiometers put into use each year go into industrial plant applications and only one-tenth into laboratory service. This is not due to any falling off in the laboratory uses of potentiometers, but rather to the rapid increase in industrial plant uses of the instrument, in the form of portable indicating potentiometers and automatic recorders and controllers.

# Tie Line Load Control

**Regulation of tie lines interconnecting two electric power systems is a problem of load control rather than one involving principally system frequency; for best results, the control equipment must be automatic. Apparatus developed to meet this need is described in this article, and the results from two years' operating experience are outlined.**

PARALLEL or interconnected operation of several power systems has brought to the fore a new and most important problem; namely, that of controlling the interchange of power between the several systems. This problem first came into prominence under the name of frequency control and many engineers attacked it from that point of view. As a matter of fact the problem is one of load control instead, and as yet little has been done toward its solution. The division of power in a loop under the control of phase shifting equipment is a related problem, but should not be confused with the control of total interchange by the prime mover governors. Attempts to regulate two or more interconnected systems with an automatic frequency regulator on each system promptly will develop the fact that the load variations on the systems will be so dissimilar that power flow over the tie lines cannot be regulated in this manner. In fact it has been observed in some cases that when the bulk of the load change falls upon one system, the power flow over the tie line exceeds the load change by the amount required to accelerate or retard the systems.

Recognizing the problem as one of load rather than frequency control, the Duquesne Light Company several years ago enlisted the coöperation of several equipment manufacturers in a series of load control experiments. The tests were made on the 36,000-kva. 132-kv. tie between the Colfax station of the Duquesne Company, and the Springdale station of the West Penn Power Company. As a result of this and continued investigation, automatic load control

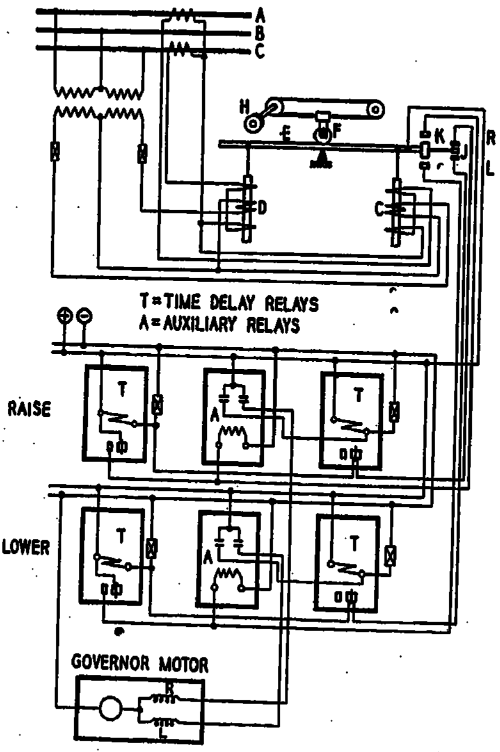

**Fig. 1. Westinghouse solenoidtype automatic load regulator for interconnecting tie lines**

With weight F immediately above the fulcrum, arm E is balanced and requires zero watts in coils C and D to maintain balance. Any power flow through the coils will cause the arm to raise or lower depending upon the direction of flow. For small changes in load contact J engages either the "raise" or "lower" stationary contacts R or L. These contacts send an impulse to the governor motor through time delay relays approximately $2^1/_2$ sec. after the contacts have closed. If the period of contact engagement is less than $2^1/_2$ sec. no correction results. A second set of time delay relays is provided to limit the length of impulse delivered to the governors to a predetermined value. To take care of large load changes, a second set of contacts K is provided to operate the speed changer motor directly through auxiliary relays without time delay. Contacts K are set to close for approximately 10,000 kw. change in load, but hunting of the regulator in this zone is prevented by the opening of these contacts at 5,000 kw. Below this value the auxiliary contacts J to return the line load gradually to normal.

---

Based upon "Tie-Line Control of Interconnected Networks" (No. 31-127) presented at the A.I.E.E. Pacific Coast convention, Lake Tahoe, Calif., August 25-28, 1931.

over the tie line and automatic control of the generator output in accordance with a predetermined program, both being supervised by or subservient to automatic frequency control, have been in successful operation at the Colfax station for some time. While many improvements no doubt are yet to be made, operation of existing equipment exceeds expectations extant at the time the investigational work was started some two years ago.

The maximum economy possible as a result of interconnection will not be obtained unless the most efficient loadings of the several generating units on the interconnected system are adhered to closely. This loading must be anticipated and must take account not only of the inherent efficiency of the generating station and units, but numerous other factors. Since maximum economy cannot be obtained with manual control, for the most advantageous operation the control must be automatic. Such control must be simple, reliable, accurate, and easy to set for any desired division of load between generating units.

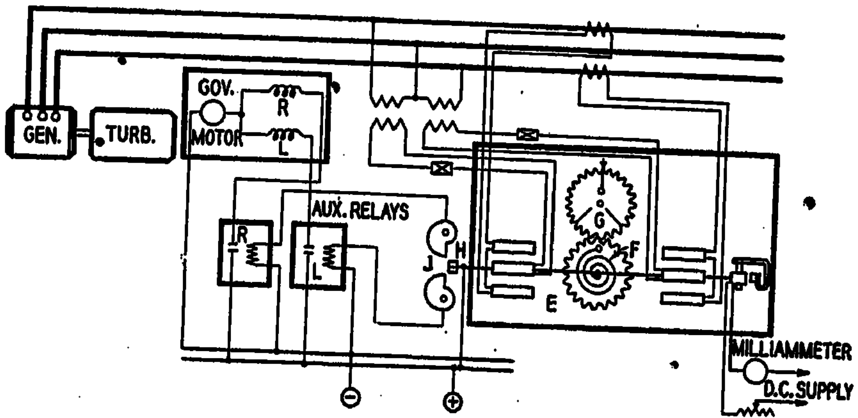

**Fig. 2. Westinghouse Kelvin-balance type automatic tie-line load regulator**

A calibrated spring F attached to a geared disk allows the torque due to the power in the Kelvin balance to be neutralized by rotating the disk G to the right or left; a balance thus can be made at any load within the limits of the spring F. Variations in load cause the balance to deflect contact H which in turn makes contact with the motor-driven rotating cams J thereby routing "raise" and "lower" impulses to the governor motor. As the unbalance decreases the period of contact engagement with the cams decreases and the duration of impulses to the governor motor also decreases thus providing an anti-hunting feature. Disk G can be rotated by a position transmitter, or a D'Arsonval element may be attached to the lever E to counteract the torque in the balance, making the device readily adapted to remote control

Performance of a tie line connecting two large power systems involves the rate of load change, and the inertia and sensitivity of the prime mover governors, as well as the electrical characteristics of the line. A load change on one system causes a redistribution of the load between the various prime movers, and also a transient distribution which occurs during the period of adjustment to the new load. This transient condition is not noticeable in a closely tied system such as the average metropolitan utility. However, if there is only one tie line connecting two systems, these load transients are concentrated and assume considerable importance. The chief requirements of a successful tie-line load regulator therefore are that it must not respond to these small *transient* load changes, but it must respond to small *sustained* changes. However, when large load changes occur the regulator must respond whether such fluctuations are temporary or sustained.

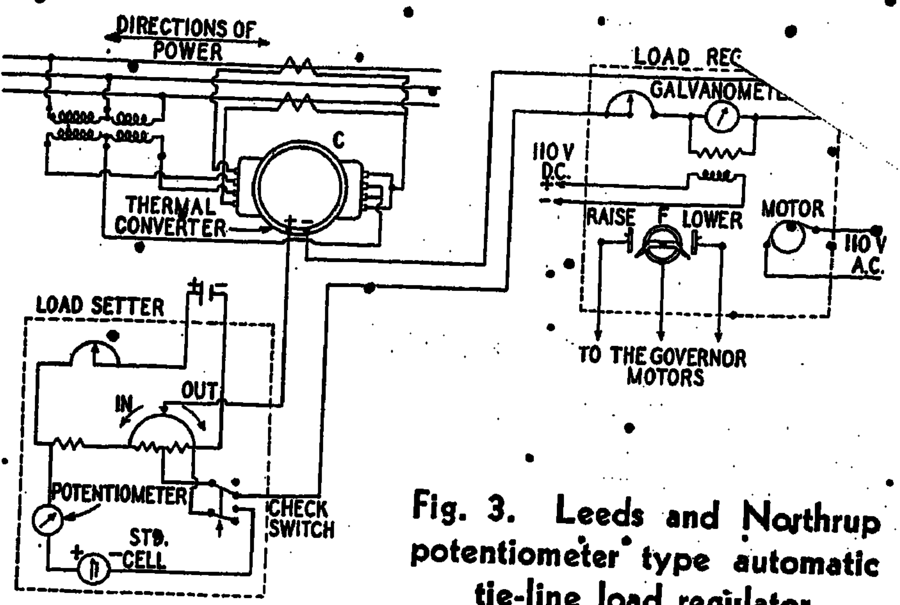

**Fig. 3. Leeds and Northrup potentiometer type automatic tie-line load regulator**

The load setter is a potentiometer with a calibrated dial, and is adjusted to give a potential equal to the thermocouple potential of the thermal converter for a given tie-line load. These two potentials are connected in opposition through a sensitive galvanometer. This galvanometer deflects in proportion to the difference in potential between the load setter and the thermocouples of the thermal converter. Any unbalance indicated by the galvanometer is checked by the rotating cam mechanism F, which delivers corrective impulses to the turbine governor in proportion to the load errors.

## TIE-LINE LOAD REGULATORS

Three types of tie-line load regulators are shown in Figs. 1 to 3. The first type (Fig. 1) was devised primarily to eliminate corrective action due to transient changes, but to respond rapidly to load changes of reasonable magnitude. It consists essentially of two solenoids connected to two phases of the tie line, and arranged to assist each other in balancing an arm which carries two sets of control contacts on its outer end. Time delay relays prevent the regulator from responding to small transient changes. This device has shown considerable promise, in that it does not cause corrections to be made which must be counteracted immediately by those of a reverse order.

A large change of turbine loading to counteract load in a tie line results in considerable energy being supplied to the system to accelerate it while changing the phase angle relation across the tie line. It can be seen that after the phase angle is changed this energy still is available to supply load, which results in an overshooting of the proper value. It is essential that any regulator responding at a rapid rate must have a wide zone about the final position in which the load corrections are made in small increments.

This first regulator is not well adapted to remote control, and for applications involving this feature, another design utilizing the Kelvin balance (Fig. 2) has been developed. No time delay relays are used with this device; it will cause more corrective impulses to be delivered to the governor motors than the device first described, although it is somewhat slower in correcting large errors due to rapid changes of load. Under average conditions, however, it will maintain a closer integrated load.

Fig. 4. Automatic program load controller for use with tie-line load regulators

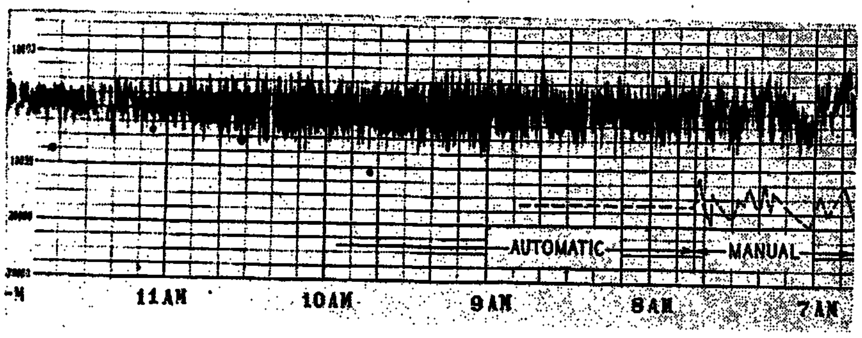

Fig. 5. Comparison between manual and automatic control. Broken line shows average of load swings

The solution of the problem of tie-line control offered by the Leeds and Northrup Company consists essentially of a master element comprising a thermal converter and a load setter as shown in Fig. 3. The thermal converter is similar to the Lincoln thermal demand meter except that instead of using a bi-metal strip to indicate the kilowatt load, thermocouples are inserted which produce a potential for transmission to suitable receiving apparatus. This device tends to change the turbine loads until the tie-line load flowing through the thermal converter sets up a potential equal to that of the load setter. This control gives very satisfactory operation.

## Program Load Control

In the past where frequency control has been adopted, common practise has been to confine the regulating to one station and usually to one generating unit. When the regulating device controlled more than one unit, the division of load between units sometimes was found to be erratic; therefore load balancing schemes were devised to enable the various units to carry their proper share of load increments.

These devices are relatively simple and perform satisfactorily, but the principle of dividing all load increments proportionately between units in a steam station does not necessarily make for maximum efficiency. Most operators have considered the output of the machine and have not taken into account the inefficiency due to operating with steam control valves in a throttling position. In the equipment developed to meet the requirements established by the Duquesne company operators, load scheduling is based upon turbine valve positions rather than upon generator output. Thus each turbine is maintained at its most efficient valve opening regardless of the effect of the many variables entering into the position of the valve with reference to the load.

In Fig. 4 may be seen a schematic diagram of equipment used to obtain automatic division of load in accordance with the predetermined program loading at the Colfax station. Six generating units are installed in this station, two of them of 60,000-kw. capacity each; two of 41,250 kw. each; and two of 30,000 kw. each. On the larger steam turbines the nozzles are arranged usually in three groups, each fed from the primary, secondary, and tertiary valves, respectively. These valves are equipped with auxiliary switches to establish the proper sequence of loading. Referring to Fig. 4, the motor-operated selector switch routes the "raise" or "lower" impulses from the tie-line load regulator through the load scheduling device to the turbine governors. In order to simplify the description and diagram as much as possible only two machines have been shown, each with one primary and one secondary valve.

Six loading schedules are shown in the table (Fig. 4); to set up any one of these schedules, a system of receptacles and plugs is used, four machine receptacles and four sequence receptacles being required for the case illustrated. The selector switch has four independent contact arms, two of which are used for routing the "raise" or "lower" impulses and two for controlling the selector switch driving motor. The position of the selector switch is determined by the position of the valve auxiliary switches and also by the way in which the machine and sequence receptacles are connected by jumpers. For example consider that machine No. 1 primary receptacle is connected to sequence receptacle No. 1, No. 1 secondary to sequence 2, No. 2 primary to sequence 3, and No. 2 secondary to sequence 4 receptacles. The operation then would be as follows with both machines carrying minimum load and the selector switch in position 1: on increasing the load, an impulse from the regulator is routed through to No. 1 governor motor.

After the load has increased to the point where the primary valve is wide open, the auxiliary switch on this valve makes contact energizing the forward control of the selector switch driving motor on the next raising impulse. The selector switch rotates in the forward direction until cut off by the forward contact breaking the circuit with the first contact. The width of the forward and backward contacts are such that the motor will drift to the next position after the control circuit is broken. The switch now is in position 2 and the raising or lowering impulses are still routed to No. 1 governor motor. In the same manner, the selector switch transfers to the next position after the secondary valve on machine No. 1 opens fully. With decreasing load the selector switch returns, the motor being energized through the "backward" selector switch arm and the valve switch contacts which are closed when the valves are closed. The forward and backward auxiliary relays seal in so that the selector switch travels at least one position and also breaks the control circuit from the regulator so that control is broken during the transfer.

## OPERATING EXPERIENCES

The instantaneous speed of any system is a function of the system load and of the setting of the turbine governors; hence, with any given setting the speed of the system will vary as the load changes. If two systems are interconnected through one or more lines, the speed of the entire interconnection becomes a function of all the governors and of the total load; the generator load does not bear a direct relation to the demand on that particular system, but since it is a function of system speed, the excess demand must be supplied through the interconnecting tie lines.

If the two systems under control are of the same size and have approximately the same load characteristics, it is possible for them to remain in parallel for reasonable periods of time when operating on straight speed-governor control without overloading the tie lines. In such interconnections, it is customary for the system controlling the tie line to adjust its governors to maintain 60-cycle frequency if this correction will tend to correct the tie-line loading. With frequency control on one system, all of the load changes occurring on the entire interconnection obviously will appear eventually on the units under automatic control, so that all the net load changes of the system without frequency control will appear in the tie line.

Observation on the Colfax-Springdale tie line for a period of two years has shown the foregoing reasoning to be correct. It is generally assumed that tie-line load control tends to make frequency control more difficult to obtain. This is based upon the assumption that all load changes on one system must flow over the tie line and be compensated for by the frequency-control equipment before the tie-line equipment has functioned. That is to say, the load change is corrected first by the frequency regulator and later by the tie-line control, which in turn requires that the frequency regulator drop an amount of load equal to that picked up by the tie-line load control. This reasoning would be sound if the frequency-control equipment were much faster in response than the tie-line regulator. As a matter of fact, experience has shown that the two types of control work together satisfactorily although possibly at the expense of increased frequency of operation during some periods.

It has been observed also that the use of tie-line regulators affects the permissible neutral zone of the frequency regulators on the interconnected systems. The initial installation of tie-line load control at Colfax was made at a time when the West Penn company was maintaining its system frequency to within ±0.05 cycle by means of automatic frequency control devices at its Windsor station. Later, in order to reduce the overloading of other tie lines, the frequency was allowed to vary as much as ±0.15 cycle. This resulted in a more erratic power flow over the tie line and an increase in corrective operation of the tie-line regulator. It is felt that while the solution to tie-line load swings may be put off temporarily by allowing frequency to drift, eventually system speeds will have to be held rigidly at 60 cycles and load control adopted on all tie lines to permit maximum utilization of existing transmission facilities between the interconnected systems.

Another interesting observation has been the effect on the normal band of power swings with manual and with automatic control, respectively. This comparison is shown in Fig. 10. Under manual control the average load drifts without any appreciable change in the width of the band of power swings; whereas with automatic control the average load is maintained very close to the desired amount, but the band of power swings is enlarged greatly.

In October 1930 tests were conducted by the Duquesne and West Penn companies to determine the rate of response of the tie-line control and of the frequency control to rapid load changes. This was accomplished by rapidly lowering the load on the Colfax station 30,000 kw. and allowing the load and frequency controllers at the Colfax and Windsor stations, respectively, to correct the load distribution and frequency without manual assistance. In order to analyze the instantaneous load shifts which ensued, high speed test meters were used; the results of two typical tests are shown in Fig. 6. In both tests, when 30,000 kw. was dropped at Colfax the power flow over the tie line increased almost simultaneously and at the same rate as the load was dropped. This initial division is a characteristic of interconnected systems when the load change occurs at the end of the tie line opposite from the point of frequency control. Without tie-line control the Windsor station being under frequency control would have picked up the entire 30,000 kw. dropped. However, the curves show that in both cases the tie-line load control had accomplished considerable correction by operating on Colfax unit No. 1 before the frequency regulator at Windsor had caused that station to acquire much of the load dropped.

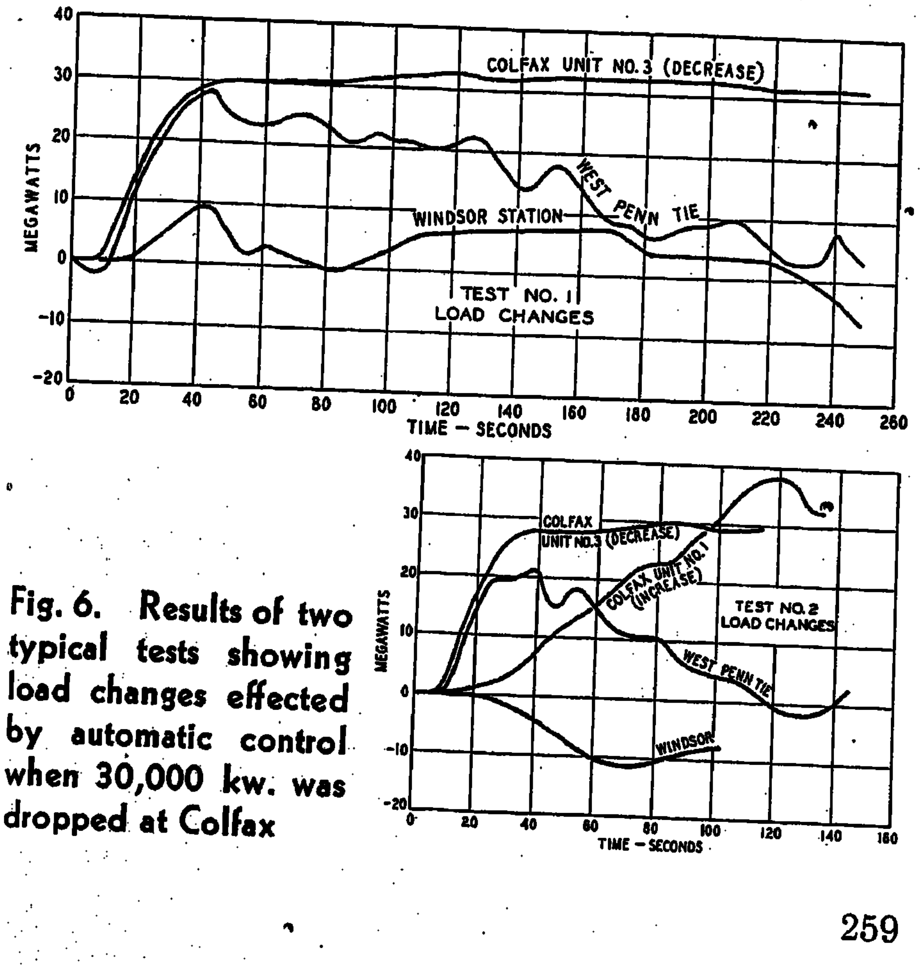

**Fig. 6. Results of two typical tests showing load changes effected by automatic control when 30,000 kw. was dropped at Colfax**

Both tests were similar except that the speed of response of the load regulator was increased in test No. 2. It may be noted that in this second test the load was dropped at Colfax station but was not picked up at Windsor. This was due to the latter station dropping load faster to compensate for load changes on its own system, and incidentally is a good illustration of the advantages of load diversity through interconnection.

## CONCLUSIONS

On the basis of the foregoing, it may be said that:

1. Automatic tie-line load regulators and program loading equipment have been developed to a commercial stage.
2. Tie-line load regulators on one system can be operated satisfactorily in conjunction with frequency regulators on a connected system.
3. Tie-line control may be used to reduce load fluctuations between interconnected systems.

---

# Variable Ratio Frequency Converter

**Two synchronous-induction frequency converters with controllable frequency ratio and full automatic features were chosen to tie a 25-cycle and a 60-cycle system. Consideration of generation, loads, load cycles, and stability of both systems led to the selection of this type of unit.**

E. L. HOUGH
ASSOCIATE A.I.E.E.

Both of
Union Electric Light &
Pwr. Co., St. Louis, Mo.

COINCIDENT and continual growth of the 25-cycle and 60-cycle systems of the Union Electric Light and Power Company created a series of problems which called for simultaneous solution. These requirements were essentially:

1. Need for additional 60-cycle prime capacity to meet a normal yearly increment in 60-cycle load.
2. Need for additional 25-cycle reserve capacity to supply overgrowth of a 25-cycle system load beyond the ability of a run-of-river hydroelectric plant and a small 25-cycle steam reserve plant to adequately handle it.
3. Recovery of annual loss of 60,000,000 kw-hr. in run-of-river hydroelectric plant due to deficiency in 25-cycle system load at times.
4. Need for 40,000 kva. in synchronous condenser capacity at St. Louis to operate on end of 136-mile, 60-cycle transmission line.
5. Improvement in 25-cycle system operation if a small amount of corrective kva. could be added at St. Louis end.

A coordinated study indicated that more efficient use of the generating ability of both systems would be possible if they were connected by adequate frequency converter capacity, at the same time securing the complete satisfaction of all but the first point above enumerated. Keokuk, while developed to a maximum capacity of 135,000 kw. as a run-of-river, 25-cycle, hydroelectric plant, was limited at times to a maximum capacity of 70,000 kw., so that the requirement of 60-cycle prime capacity could not be met solely by the installation of frequency changer capacity. However, the 60-cycle system, supplied entirely from steam plants, was being augmented by the addition of a huge storage hydroelectric plant at Bagnell, to satisfy the 60-cycle system demand.

Interconnection of two hydroelectric plants of different frequency by frequency converters has obvious advantages, but when additional system requirements may be satisfied in the same installation with only a minor increase in cost, the importance of such an installation is evident. It was determined that the frequency changers should have the following characteristics:

1. The set should be able to transmit power in both directions in order to provide additional capacity to the 25-cycle system in times of water power deficiency; also access to the 60-cycle system of an additional 60,000,000 kw-hr. annually from the 25-cycle hydroelectric plants. It was found that the transfer to 25 cycles to take care of the load requirements on this system thus could be made without additional investment in 60-cycle generating equipment.
2. The machine should have such characteristics as would provide interconnection between a fixed capacity 25-cycle generating system of 175,000 kw. and an increasing 60-cycle system capacity with a present rating in excess of 450,000 kw.
3. The 60-cycle end of the machine should combine approximately 50,000 kva. of synchronous condenser capacity for use in bringing Osage power into the St. Louis district.
4. Either end of the machine should be constructed to run separately in the event of diversity between the watersheds of the Keokuk plant and Osage plant requiring such operation. This might be required also in the interest of economy in operation.
5. Two machines of one-half capacity each would be preferable to one, because then failure of one machine still would permit adequate operation in most cases.

The required size of frequency converters was determined from load requirements. Two sets of 20,000-kw. rating were chosen as combining most suitably the requirements of load transmittal, spare capacity, and synchronous condenser capacity. The type of set to be used was the subject of considerable investigation. It was found that there were five types of machines available; namely,

1. The synchronous-converter frequency converter
2. The synchronous-synchronous converter

---

Based upon "Interconnection of the 25- and 60-Cycle Systems of the Union Electric Light and Power Company" (No. 31-137) presented at the A.I.E.E. South West District meeting, Kansas City, Mo., Oct. 22–24, 1931.

3. The synchronous-induction converter
4. The fixed-ratio synchronous-induction converter
5. The variable-ratio synchronous-induction converter

The synchronous-converter frequency converter consists of two synchronous converters on independent shafts, one operating from each of the systems to be interconnected. All power transferred is received at one frequency, converted to direct current and reconverted to alternating current of the other frequency. The fact that this machine has never been built in large sizes definitely precluded its use in this case.

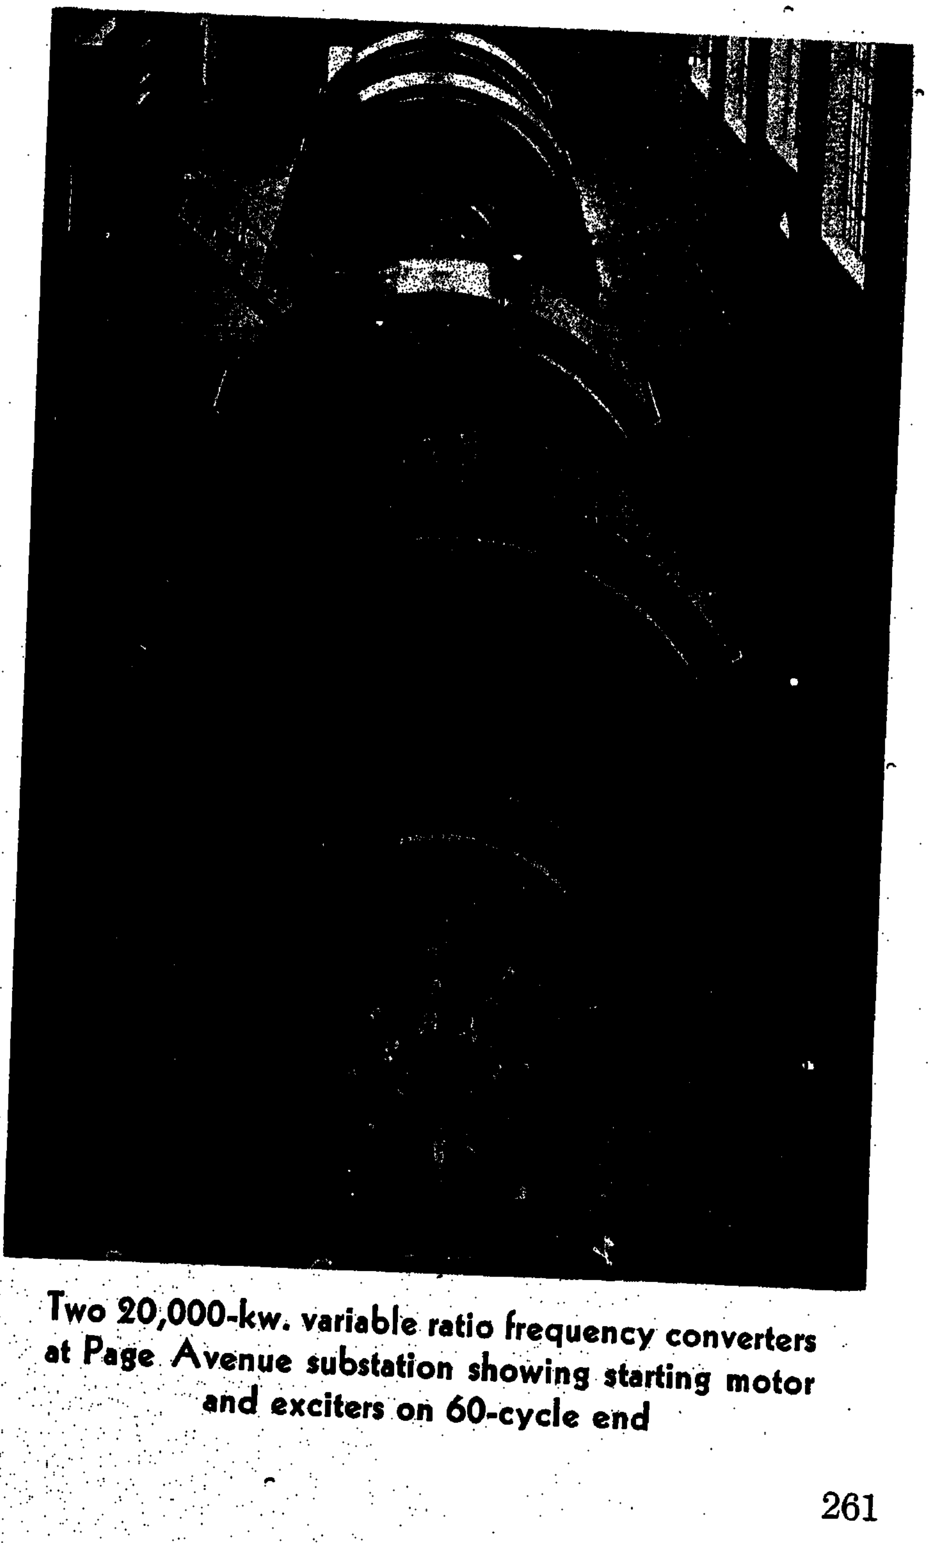
The synchronous-synchronous converter consists of two synchronous machines on a common shaft, one operating on each system. This machine is the one most commonly used. The frequency ratio is fixed and therefore the set constitutes a rigid frequency tie between systems within the limits of pull-out torque of the individual machines. The load is completely reversible, the load transmittal being determined solely by prime mover governing and not controllable at the set. Power factor control of both ends is available over a wider range than in any other type of set. The efficiency is high, preliminary estimates indicating that 95 per cent might be expected on a 20,000-kw. unit. This set is essentially simple in construction and operation and requires but few auxiliary machines. The paralleling of machines requires considerable precision in synchronizing. For example, starting from the 60-cycle end there is only one chance in twenty-four that the machine will "come up" right. Load division between sets is accomplished readily by stator shifting. Since machines of this type in the rating proposed already had been built no untried designs would be necessary.

Records indicated that the reliability of this type of set was good provided the machines were of sufficient capacity to withstand shocks incidental to system disturbances. The chief difficulty in applying this machine lies in determining the proper size of unit required. An examination of data available indicated that not less than from 10 to 25 per cent the capacity of the smaller system would be required. This application would require a set of from 18,000-kw. to 40,000-kw. capacity. Conservatively, it appeared that units of 30,000 to 40,000 kw. each would be required, and since load transmittal requirements did not justify units of this size, this type of converter seemed undesirable.

The synchronous-induction converter consists of a synchronous machine direct-connected to an induction machine of either the wound rotor or squirrel cage type. The frequency ratio of this set varies according to the load on the set and is not controllable at the set. The load is reversible if sufficient synchronous capacity is available to supply the exciting kilovoltampere of the induction machine, but there is considerable change in frequency ratio with change in direction of power flow. Load control is determined by prime mover governing. The set is relatively stable, the stability being determined chiefly by the pull-out torque of the synchronous machine. Power factor control is available on the synchronous end of the set but not on the induction end. The efficiency is relatively low. The set is simple in construction and operation and of good reliability.

The fixed-ratio synchronous-induction converter consists of a synchronous machine and a wound rotor induction machine with the rotor of the induction machine and the stator of the synchronous unit connected to the lower frequency system, with the stator of the induction machine connected to the system of higher frequency. This converter is sometimes called the "general transformer" since it can be arranged to transform phase, frequency, and voltage. A peculiar characteristic of this set is that it constitutes a voltage tie between systems of different frequencies in a manner analogous to a transformer on a single-frequency system. In several cases the set has been used to obtain certain advantages which this characteristic gives under particular circumstances. In the case at hand this feature was undesirable.

The frequency ratio of this converter is fixed by the design and is rigid. The load is reversible and the load control is obtained by prime mover governing. Stability is good and limited power factor control is available by a combination of transformer tap changing and synchronous machine field control. The efficiency is relatively high and operation is relatively simple although there is only one chance



Two 20,000-kw. variable ratio frequency converters at Page Avenue substation showing starting motor and exciters on 60-cycle end in ten of correct polarity and phase on the second unit. This type of machine has been reliable in service and has been built in large sizes.

The variable-ratio synchronous-induction converter consists of a synchronous machine direct-connected to a wound rotor induction machine provided with suitable regulating machines, the number and type varying with the particular manufacturer. The distinguishing feature of this set is that the frequency ratio is variable. Voltage and load disturbances are reflected through the set to a lesser degree than with other types. The load is reversible and the load control within the design limits of the set is accomplished at the set itself without dependence on prime mover governing. Stability is good, the maximum load transmittal being determined by the pull-out torque of the synchronous machine, the relative speed changes of the two systems, and the speed of operation of the regulating equipment. It is interesting to note that if the automatic regulating equipment is not working, a relative speed change of twice the slip of the induction machine is required to change from full load in one direction to full load in the other; whereas with fixed ratio types this reversal occurs with only a small phase angle change. In the synchronous machine power factor control can be obtained over a wide range and in the induction machine, over a limited range determined by economic design considerations. Efficiency is good although not so high as on synchronous-synchronous machines; the efficiency varies with variation in frequency ratio. Although simple of operation, the set is somewhat complex. Its main advantages lie in stability, ease of starting, and load control. The sets had been built in the size contemplated and component machines of larger size produced.

**The two 20,000-kw. frequency converters, showing the Scherbius regulating equipment for the 25-cycle induction unit in the foreground**

Based on this analysis it was decided to purchase two variable-ratio synchronous-induction converter sets, each set to be capable of transmitting 20,000 kw. from the 25-cycle to the 60-cycle system or vice versa with simultaneous and opposite variations in normal frequency of one-half cycle in each system; that is, each set was to be capable of transmitting full load from either system to the other throughout frequency variations from 24.5/60.5 to 25.5/59.5 cycles. This would permit a fairly wide variation of frequency in one system if that of the other were fixed, the range being affected by the direction of load transmittal because of the natural slip of the induction machine.

The machines, completely automatic in operation, are of the six-bearing horizontal type with adequate provisions for movement of stators on both of the large machines to permit easy maintenance or repair. A split coupling is provided between the machines, with the starting motor and d-c. exciters located on the 60-cycle end to permit independent operation of the 60-cycle unit as a synchronous condenser, if required. Each unit occupies an area of approximately 13 x 60 ft. The machines are of the semi-enclosed type, drawing filtered air from the room and discharging it into the basement. The ventilation requirements are 150,000 cu. ft. of air per min. per set.

The frequency converters in several months of operation have met their expected requirements fully. The average over-all efficiency has been approximately 90 per cent during the first six months' operating period, the normal load cycle requiring operation part of the day as 60-cycle generators, and the balance of the time as 25-cycle generators, supplying 25-cycle relay power.

It has been found that the inherent ability of the machine to change load gradually with system speed changes has been of marked benefit in stabilizing the systems. For example, with the set feeding the 25-cycle system, a voltage drop may cause the loss of considerable 25-cycle load with consequent speeding up of that system. The load reverses and the frequency is held to a small departure from normal. The occurrence of a short circuit on the 25-cycle system reduces the exciting voltage to a low value and consequently the decrement curve shows a very rapid drop after the first few cycles; this has the effect of holding the interrupting requirements on oil circuit breakers to a low value. The corrective capacity in the 25-cycle induction units varies from zero at full load to 16,000 kva. at no load and exerts a remarkable stabilizing influence on the 25-cycle voltage. The 60-cycle machines are equipped with high-speed excitation systems so that the 60-cycle voltage is held within close limits.

The machines as installed cannot be operated unless a 25-cycle exciting source is available, although minor modifications would permit d-c. excitation to bring up a dead system. In several cases where the 25-cycle bus voltage has been dropped to a very low value by faults close into the bus, the machines have resynchronized themselves without any difficulty. It is of interest that the voltage of the induction unit is always at the same frequency as the exciting source, but its value may vary through wide limits and it may be considerably out of phase with the system voltage. Consequently, the ability to resynchronize depends upon the action of the regulating equipment and the changes in relative system speeds during the interval when the bus voltage is very low.

# Abstracts

## Of Papers to Be Presented at the Providence District Meeting

INTERPRETIVE abstracts of all papers which at the time of this issue are definitely scheduled for presentation at the A.I.E.E. Providence District meeting (May 4–7, 1932) are published herewith. Papers presented at this meeting will not be available in pamphlet form, but in response to popular demand and within its space limitations, ELECTRICAL ENGINEERING subsequently may publish certain of these papers, or technical articles based upon them.

### The Parallel Type "Inverter"

By
F. N. Tompkins[1]

THE DEVELOPMENT of the thyratron or three-element hot-cathode gas-filled tube with grid-controlled arc has given electrical engineeing a new tool. Many interesting and valuable applications have been devised, among the most interesting of these being the "inverter." Its purpose is the inversion or changing of direct current to alternating current, the reverse process of the more usual rectification. With the advent of the thyratron with its high efficiency, low voltage drop, and its ability to handle the comparatively large amounts of power, the inverter gives promise of becoming of commercial importance.

Inverter circuits may be divided into two main types, series and parallel. While for the former types many data have been published and many different circuits have been devised, very little beyond the fundamental circuit has been given for the latter. The purpose of this paper is to present the results of a study of the parallel-type inverter which was undertaken to secure a better understanding of the function of each part and of the operation as a whole. There is presented the information necessary to make the operation of thyratron circuits understood. The principles of operation of the inverter are developed by means of simple diagrams, and from complete sets of oscillograms the actual operation is shown.

It is demonstrated that the method of operation differs from that usually assumed, inasmuch as the capacitor performs the function of giving the correct phase relation between the input current and the induced transformer primary voltage, rather than providing a sudden reversal of potential on the anode of the tube being stopped. This reversal is provided by the induced primary voltage. The effects of low power factor loads with both leading and lagging current are shown by oscillograms and the effects of improper circuit constants when operating at low power factor are given.

The output wave form under conditions of full load unity power factor is analyzed and it is shown that with the proper circuit constants the voltage wave is a fair approximation of a sine wave. For any given set of circuit constants the output wave forms change with the character and degree of loading. When reasonably good output wave forms are secured, the voltage regulation is poor but the efficiency is high. Changes in the circuit which give better regulation cause poorer wave form so that in the design of this type of inverter circuit a balance must be chosen between these two factors. Curves of efficiency and regulation, the latter showing the effects of different values of capacity, are given and briefly discussed. (Pamphlet copies not available.)

### Engineering Features of Phanotron Tubes

By
H. C. Steiner[2]
A. C. Gable[2]
H. T. Maser[2]

DURING the last few years vacuum tubes have found an ever-enlarging field in industrial applications, the more recent gas filled electron tubes providing the engineer with a tool even better suited to his needs. Among the outstanding engineering features of the gas or vapor filled electron tube (to which the name phanotron has been applied) are as follows:

1. The tubes are static devices, the complete functions of which are performed through the movement of electrons and ions.
2. The efficiency in controlling or converting power is high. Tube efficiency ranges from 95 per cent to over 99 per cent.
3. Control is flexible and the power required for control is small.
4. The speed of operations as a relay is extremely fast, and in addition, the tube may function cycle by cycle or intermittently without the wear that accompanies the operation of mechanical devices.
5. Noise and vibration are entirely absent.
6. Current carrying capacity is available in the range from a few milliamperes to several hundred amperes.

In practise the name phanotron has become associated with the two-element or simple rectifying tube. The phanotron tubes in which the starting of the conduction period is controlled electrostatically by the action of one or more grids have been termed thyratron tubes. The design, characteristics, and operation of these types of tubes are described in this paper, ratings being given.

Fundamentally, applications may be divided into two classes; namely, rectifiers converting alternating current into direct current with or without voltage control, and inverters changing direct current into alternating current. Oscillograms are given in the paper for a bi-phase rectifier with voltage control, supplying loads that are predominantly resistive, inductive, and capacitive. The operation of a single phase inverter is described and oscillograms are given for the voltage and current conditions of one of the tubes, the output voltage, and the commutating condenser current. (Pamphlet copies not available.)

### Subharmonic Frequencies Produced in Non-Linear Systems

By
W. M. Goodhue[3]

IN BRIDGE measurements, harmonics, due to a non-linear load being measured or due to the power supply may fail to be balanced at the same time the fundamental is balanced. This impresses on the detecting system a wave containing a large proportion of harmonics, or, at true fundamental balance, harmonics without fundamental component. The detecting system contains magnetic materials and may include a vacuum tube amplifier. Different observers have found errors which they traced to the apparent conversion of part of the harmonics into a fundamental component.

It is shown in the paper that a single non-linear device, such as a vacuum tube operating on a curved characteristic, usually converts parts of an input, consisting of third and fifth harmonics only, into a fundamental component. This is distinct from detector action which occurs at the same time and yields a second harmonic, and also from modulation which requires two stages of amplification, one acting as modulator and the other as detector.

---

[2] Genl. Elec. Co., Schenectady, N. Y.

[3] Harvard University, Cambridge, Mass.

For moderate amplitudes, a Taylor's theorem expansion of the characteristic of the non-linear device is employed and resulting formulas for fundamental and harmonics tabulated for an input of two harmonics of arbitrary frequency, magnitude, and phase angle. The Taylor coefficients of the power series expansion which are involved in the resulting formulas are determined graphically, as the graphic method is more informative, less troublesome, and more accurate than attempting to obtain directly the cubic equation by a three point method, etc. The effect studied is essentially a third order effect.

For large amplitudes the method is entirely graphic, and even ordinary methods of wave analysis are not suitable due to the small fundamental and large harmonics. Graphic integration is employed and comparisons made of r.m.s. value, average value, and magnitude of fundamental. Also an example is worked out with an iron alloy (linking a coil) instead of the vacuum tube amplifier. Usually the effect with magnetic materials is further complicated by eddy currents and cyclic loop effects. (Pamphlet copies not available.)

# A General Theory of Systems of Electric and Magnetic Units

By
V. Karapetoff[4]

GENERALLY it is conceded that the present situation in regard to the electric and magnetic units is far from satisfactory, for the following reasons:

1. Two or three systems of units are in general use (C.G.S. and practical) at least two more are employed by some prominent writers (the Gauss system and the Heaviside-Lorentz system) and new ones are occasionally being proposed.

2. The absolute magnitudes of some units fixed by international agreement or in general use otherwise are considered as being too small or too large by some investigators who urge the adoption of smaller or larger units.

3. There is an appreciable disparity between the "absolute" C.G.S. units and the corresponding "international" units.

4. The physical dimensions of the electric and magnetic quantities are believed by some scientists to be different in different systems of units. Some physicists even believe it legitimate to assign an arbitrary physical dimension to a quantity; as, to assume absolute permeability for any medium to be a numeric.

In this paper it is pointed out that a system of electric and magnetic units may be shown to be characterized by five parameters; namely, a numeric $n$ which gives the ratio between the nominal density of electric displacement used in that system and the *true* density; a numeric $p$ which gives the corresponding ratio for magnetic flux densities; a physical conversion factor $k$ which converts a given volume of current into the corresponding magnetomotive force; the absolute permittivity $\kappa$; and the absolute permeability $\mu$. On the basis of these five parameters, the principal fundamental equations of electricity, magnetism, and electromagnetic waves are written in what is called the general system of units without assigning definite values to these parameters. It is shown also that the five parameters must satisfy the equation $vk = \sqrt{np/\kappa\mu}$ where $v$ is the velocity of propagation of electromagnetic waves in that particular medium to which $\kappa$ and $\mu$ refer; otherwise the five parameters may be chosen artibrarily.

By giving these parameters specific values, seven different systems of units are derived; namely, the electrostatic, the electromagnetic, the practical, the Gauss, the Heaviside-Lorentz, one which the author calls the compromise system, and the ampere-ohm system introduced by him some 20 years ago. The characteristics, the advantages, and the disadvantages of each system are briefly discussed, and it is shown how to deduce a new system of units from the general system.

At the end of the article a discussion is given on the physical dimensions of various electric and magnetic units. It is stated that four fundamental units are necessary for a system so that if certain length, mass, and time intervals are taken as three fundamental units, a fourth electric or magnetic unit must be added, for example, the permittivity or the permeability. In the ampere-ohm system, two mechanical fundamental units are used, the centimeter and the second; also two electrical units, the ampere and the ohm. Physical dimensions of $k$ are unknown. (Pamphlet copies not available.)

# A Proposal to Abolish the Absolute Electrical Unit System

By
E. Weber[5]

THE FUNDAMENTAL discovery that the ratio of the "absolute" electrostatic unit to the "absolute" electromagnetic unit of electric charge, predicted as velocity, was apparently identical with the velocity of light brought about an unforeseen confusion in the field of electrical units. The use of various absolute dimension systems expressing the electric and magnetic quantities by means of the three mechanical fundamental dimensions influenced the writing style of formulas and caused the introduction of arbitrary factors.

A veritable flood of articles and papers has been published in the important periodicals of the world, concerned either with a new system of electric and magnetic units or dimensions, or with a comprehensive basic system of mechanical units. None of them has succeeded as yet, because of the attitude of respect toward the classical "absolute" systems. This paper aims to prove conclusively the incorrectness of these classical dimension systems and to propose "natural systems" which, it is hoped, may finally settle the differences and put the electrical unit systems upon a sound basis.

The absolute dimension systems expressing the electric and magnetic quantities by the three dimensions of mechanics are shown to be incorrect since the consequent use of proper mathematical statements leads to impossible results. However, the definitions of the absolute units, as well as the "practical" units in electromagnetics have a sense quite independent of the dimension systems. It is shown that the simplest and, as it seems, apparently the only true solution is to extend the two mechanical dimensions systems, known as technical and physical systems, into the field of electromagnetics by adding a new fundamental electric dimension. This gives two electrical systems, the electrotechnical dimension system with all the practical units and the electrophysical dimension system with all the absolute units. (Pamphlet copies not available.)

# Performance Calculations on Induction Motors

By
C. G. Veinott[6]

THE MEANS given in this paper for calculating the performance of both single phase and polyphase induction motors is intended primarily for calculations from previously determined design constants. By actual trial the methods have been found to be very easy to learn and use even without a knowledge of induction motor theory, and are very rapid.

In the past many of the popular calculating methods for induction motors made use of various forms of circle diagrams, charts, families of curves, etc. Both methods developed in the present paper are arrived at by a simple straightforward use of complex algebra, and consist of the filling in of the blank spaces of a calculating sheet especially prepared for this purpose and which can be incorporated on the regular design sheet. The methods are inherently as accurate as the best methods proposed to date, and are more accurate than many of the older methods. Further, they are well suited to rough calculation, ordinary calculation, or exact calculation.

The single phase calculation method is based upon the cross-field theory, the principle being to set up and solve by the algebra of complex quantities three simultaneous equations for the currents in the three circuits of the motor; namely, primary circuit, transformer circuit of the rotor, and the secondary cross-field circuit. The new method is faster than previous graphic methods, and also is more accurate. The independent variable is the rotor speed.

The polyphase calculation method is based upon the equivalent circuit and the equivalent circuit is based upon the revolving field theory. The independent variable is the slip. As it is not necessary to compute the large number of curves required for some of the previous methods, an enormous amount of time and labor is saved. Furthermore, the method distinguishes between primary and secondary leakage. (Pamphlet copies not available.)

# Measurement of Stray Load Loss in Polyphase Induction Motors

By
C. J. Koch[2]

FOR LACK of a satisfactory method of measurement, no provision is made for stray load losses in the A.I.E.E. standard efficiency tests for induction motors. These losses may amount to from 2 to 5 per cent in squirrel cage motors from 1 to 5 hp. in size, decreasing gradually with increase in motor rating until they are less than 1 per cent for motors of several hundred horsepower. Development of an easy method of measuring stray load losses would not only rectify this situation, but also would permit the losses themselves to be studied more intensively and perhaps ultimately to be reduced greatly.

All methods of measuring stray load losses may be classified as either direct or indirect. Indirect methods aim to measure the total loss in the motor, substraction of the conventional losses yielding the stray load loss. Best known among the various indirect methods perhaps is the input-output method. Direct methods of measuring these losses are based upon the following procedure: Either the rotor or stator winding is excited by direct current with the unexcited winding short-circuited; the rotor then is revolved at synchronous speed and the power required to do this is measured. The stray load loss then is determined by subtracting from the power required to drive the rotor in this manner, the friction and windage losses, and also an amount of power equal to the $I^2R$ loss produced by the fundamental frequency current in the unexcited member.

Upon the basis of a series of tests made on both slipring and squirrel cage motors of different sizes, the following methods are recommended:

**Slipring Motors**

1. Measure the power required to drive the motor at synchronous speed with the primary winding short circuited and sufficient d-c. excitation applied to the secondary winding to cause full load current to circulate in the primary; designate the power required as $W$. From the d-c. resistance (making any corrections necessary for differences in temperature) determine the primary $I^2R$ loss and designate this as $T$.

2. Repeat the test just outlined, with the primary current equal to the magnetizing current, and determine the rotational power required and the $I^2R$ loss; these latter are designated $W_o$ and $T_o$, respectively.

3. The stray load loss, then, is equal to $W-W_o-T+T_o$.

**Squirrel Cage Motors**

1. Apply d-c. excitation to the stator using two of the stator terminals and leaving the third open; the amount of direct current required is 1.225 times the full load alternating current per terminal. Under these conditions determine the power required to rotate the rotor at synchronous speed; this is designated $W$.

2. With the rotor at standstill apply to the stator balanced polyphase voltages of normal frequency and of sufficient value to produce full load current per terminal, and measure the starting torque thus produced. A check on the correctness of the torque obtained is given by the fact that its value expressed in synchronous watts must be somewhat less (usually from 5 to 20 per cent) than the stator watts input less the stator copper loss as calculated from d-c. resistance. Then T = Synchronous watts torque − 0.142 × Syn. Speed (r.p.m.) × Torque (lb.-ft.)

3. Repeat the test just described, determining $W_o$ with d-c. excitation equivalent to normal a-c. magnetizing current and calculate

$$T_o = \mathrm{T}\left(\frac{\text{Magnetizing Current}}{\text{Full Load Current}}\right)$$

4. The stray load loss is then equal to $W - W_o - T + T_o$

In practise, the starting torque varies closely as the square of the primary current. It is desirable therefore to measure the value of $T$ at only one value of current, selected to obtain the greatest accuracy of test, and to obtain the values of $T$ at other points by proportionality. The best value of current to select for this test will depend somewhat upon the type and size of motor. If the current is too large, overheating takes place and errors arise due to incorrect determinations of conductor temperature. However, if too low values of current are used, the small torque produced in comparison with the static friction makes accurate values difficult to obtain. It is recommended that full load current normally be used for squirrel cage and ball bearing motors, while values of 150 per cent full load current are recommended for normal use on sleeve bearing motors of less than 25 hp.

It is suggested that, after confirmation or modification by other investigators, the methods outlined be taken as a basis for revision of the A.I.E.E. standards, such revision to require the inclusion of induction motor stray load losses in efficiency determination. (Pamphlet copies not available.)

# Torque-Angle Characteristics of Synchronous Machines Following System Disturbances

By
S. B. Crary[2]
M. L. Waring[2]

THE DETERMINATION of the behavior of synchronous machines during transient conditions subsequent to a system disturbance is becoming increasingly interesting and important. In determining this behavior it is essential to know the torque-angle characteristic of the given machine under conditions resulting from disturbances of various sorts. The most important of such disturbances are variations in mechanical torque, excitation voltage, amount of external reactance, and system voltage. System voltage may vary in either magnitude or angular position.

Some of these disturbances already have been treated by various authors. It is the purpose of the first part of the present paper to establish general equations from which may be derived specific equations. Starting with the fundamental relations already developed, general equations are derived for the positive phase sequence torque of a synchronous machine subsequent to the following:

1. Switching in or out of a connecting line.
2. Occurrence of a balanced three phase system fault.

The evaluation of the torque characteristics following such disturbances is of particular importance in the determination of transient stability limits, and a step-by-step method of calculation is given so that the electrical torque of a machine having any number of rotor circuits can be determined at any time of its swing. The formulas and step-by-step method presented make it possible to predetermine the effects of amortisseur windings and high speed excitation. No attempts, however, have been made to draw any general conclusions as to the effect of these two factors.

In the second part of the paper an actual case of switching out of a connecting line is calculated, and the results compared with field tests taken on the system of the New York Power and Light Corporation. These tests are described in the companion paper, "Field Tests to Determine Damping Characteristics of Synchronous Machines." Good agreement between the calculations and test results is shown. (Pamphlet copies not available.)

# Field Tests to Determine the Damping Characteristics of Synchronous Generators

By
F. A. Hamilton, Jr.[2]

PRACTICAL system tests of the damping action of generators with and without low resistance damper windings, but otherwise identical, have been made. The effects of normal variations of generator field circuit resistance, field current, and loading were investigated, and data for checking calculated machine constants also were obtained. The results of the tests presented in this paper are valuable from a quantitative, as well as from a qualitative standpoint.

The field tests proved useful in providing graphic evidence of phenomena not well understood, and in obtaining data to verify available methods of analysis and upon which to build new methods of calculation and extension of existing theory.

Low resistance damper windings were found quite definitely to assist the rapid smoothing out of balanced disturbances resulting from the switching in or out of lines, synchronizing, load changes, or the tripping of loaded generators, and three phase short circuits. The test results indicate that generator field circuit resistance and generator field current may be varied within normal limits without greatly affecting the generator damping characteristics. Also, the test data verified methods of calculation presented in the companion paper, "Torque-Angle Characteristics of Synchronous Machines Following System Disturbances." (Pamphlet copies not available.)

## Design of Capacitor Motors for Balanced Operation

By
P. H. Trickey[6]

THE PRESENT methods of calculating the full load performance of capacitor motors are quite long and tedious. A simple convenient method of calculating full load conditions is given in this paper, including the necessary theory and formulas.

It is agreed generally that a capacitor motor should be designed to operate under nearly balanced conditions at full load. This means that there shall be no transfer of power from one phase to the other and the rotor current shall be balanced. With such a design, each phase produces equal flux and the rotor operates as if it were in a two phase stator. The theory presented in this paper is based upon balanced conditions, the method being useful only when the starting torque required is not too great. In many cases the starting torque requirements determine the winding, and the motor must operate slightly unbalanced at full load, with the resultant circulating current and lowered efficiency. (Pamphlet copies not available.)

## The Electro-Matic Traffic Dispatching System

By
H. A. Haugh, Jr.[8]

VEHICLE actuated traffic dispatching systems may be used by which the traffic in a given area controls itself. By this means the duration of the green light period at any intersection is in proportion to the volume of traffic on each approach. A smooth flow of vehicles is produced which uses the intersection efficiently.

This system of traffic control consists of three main parts; namely, the detectors, the signal lights, and the dispatcher. The detector may be any one of several types, such as a mechanical switch located in the pavement, an electromagnetic unit, or a beam of light which will be interrupted by approaching vehicles. The mechanical type has been found to be the most practical.

This dispatching device for this type of system must be of extreme flexibility, and the timing of the signal light cycle must constantly change to meet the irregular demand of traffic. This operation is secured by a group of time-delayed relays, combined with a switching mechanism. The resulting operation is similar to that which would be secured by having a traffic policeman at each corner, and the speed and amount of traffic, length of time which a car has to wait, and such factors, all are taken into consideration. The right-of-way is yielded to cross street traffic when the intersection is clear, and even when it is not clear if the cross traffic has waited for a predetermined period. However, moving traffic is never interrupted unless the right-of-way has been called to the cross street by waiting traffic or by a "pedestrian period." (Pamphlet copies not available.)

## The Flexible Progressive Traffic Signal System

By
H. I. Turner[7]

A FLEXIBLE progressive traffic signal system usually makes it possible to time signals so that traffic may move east and west, as well as north and south, at predetermined uniform speeds without being obstructed by a "stop" signal after once having passed a "go" signal. The planning of such a system is a matter that requires most intelligent study and one which yields results well worth the effort. Traffic-actuated equipment seldom can be justified over pre-timed equipment, as in a great majority of congested districts the coordination of the movement of traffic through the entire district is of incomparably greater importance than the most efficient movement of traffic at any few intersections taken by themselves.

Two general types of systems are used for planning service: the first employing a central office type controller with no timing devices located at the individual intersections, and the second, that which employs a master controller at a center point and an individual controller at each intersection. All of these controllers must have facilities for adjusting the time of each cycle of operation of the signals at any intersection from a central point, the percentage of the cycle taken by "go" and "stop" signals must be adjustable over a wide range and independently, and the start of the cycle of operation at any one intersection should be completely adjustable.

The following features are important in any flexible progressive control device:

1. Minimum maintenance expense and service interruptions.
2. Facilities for manual control.
3. Facilities for shutting down the signals at each local controller and from a central point by merely throwing a switch.
4. Adjustments which can be understood easily and made over a wide range.
5. The duration of the amber light should not increase or decrease when the total time cycle is changed.
6. Means should be provided for exhibiting emergency signals by control from a central point.
7. Means should be provided for accommodating traffic during times of the day when it is very heavy on a particular street. (Pamphlet copies not available.)

## A Recent Development in Traffic Control

By
H. W. Vickery[9]
V. W. Leonard[9]

A TIMING device containing new features and having extremely wide ranges of adjustment recently has been developed as a means for meeting the problems encountered in controlling present day vehicular traffic.

In the timer, a means is provided to give three progressive relations of the signals; thereby, the progressive relation can be changed remotely to give, for example, ideal progression of traffic into a city in the morning, and out in the late afternoon, with average progression in both directions at other hours of the day.

The timer is driven by a synchronous motor. Thus, accuracy of timing and timer settings is assured. A gear shift unit in which the gears can be shifted manually or from a remote point gives provision for changing the total time cycle. A solenoid operated drum containing a predetermined arrangement of cams opens and closes the signal light circuits. Any of the modern color sequences can be obtained by proper arrangement of the cams on the drum. Momentarily, by keys in a cycle percentage dial, a revolving switch is closed a given number of times each cycle. Thus, impulses are supplied to the drum solenoid and the drum is advanced through the various periods of the color sequence. By proper arrangement of the keys any desired percentage adjustment of these periods can be obtained.

A multi-contact relay in each timer, operated over the same wires used for remote shifting of the gears, gives provision for remote control of shut down, flashing amber, and fire control. (Pamphlet copies not available.)

## The Traffic Flow Regulator

By
C. H. Bissell[10]
J. G. Hummel[10]

THE PRACTISE of assigning a definite period for the red and green lights of each traffic signal, and keeping these periods constant throughout the day and week, is subject to serious criticism. Needless delays and congestion are caused, and the obedience of motorists to traffic signals in general may be broken down.

Traffic surveys have demonstrated that there are very definite traffic peaks and valleys for each week day as well as for Saturdays and Sundays. Experience has shown that these variations occur with definite regularity. It has not been found practical or economical to send out officers to change the timing on every signal light. Also, the system of some sort of an electrical or mechanical device to record the amount of traffic and adjust the timing signals accordingly, entails an expense which cannot be justified.

[7] Eagle Signal Corp., Moline, Ill.

[8] Automatic Signal Corp., New Haven, Conn.

[9] Genl. Elec. Co., W. Lynn, Mass.

[10] Crouse-Hinds Co., Syracuse, N. Y.

A traffic flow regulator has been developed to vary the timing automatically through any predetermined cycle. For example, the device may be set to give a different signal at each of a large number of periods throughout the day, and the setting may be varied for different days of the week. In addition, certain special conditions frequently are encountered, and for these the timing device allows compensation. A system of extreme flexibility is thus secured. (Pamphlet copies not available.)

# Double Conductors for Transmission Lines

By
H. B. Dwight[11]
E. B. Farmer[11]

FOR OVERHEAD transmission lines, double conductors, consisting of a second conductor hung a few inches below the first by metallic hangers, present a number of advantages over one larger conductor. With this double construction, the two conductors are electrically in parallel and form one effective conductor of large cross-section without increasing the number of insulators or crossarms. In some cases where there is a mechanical margin of safety, it may be found desirable to add a second conductor to the present single conductor.

Among the advantages which may be secured by the use of double conductors are: a reduction of 20 per cent or more in reactance, almost entire elimination of skin effect, an increase in current carrying capacity of nearly 30 per cent, an increase in corona voltage of from 10 to 25 per cent, and in some cases the opportunity to add to the conductivity and power rating without scrapping the old conductor. The advantages are to be balanced against the extra cost due to mechanical features including hangers, increased cost of stringing, and additional wind and ice load. Since the increase in ice load is possibly the greatest disadvantage, the use of double conductors is of greatest interest to southern districts where ice load is not encountered.

In this article, formulas are given for the calculation of the electrical characteristics of double conductor transmission lines, which enable comparisons with other types to be easily made. (Pamphlet copies not available.)

# Three Phase Multiple Conductor Circuits

By
Edith Clarke

DURING the past year, the subject of power transmission by multiple conductor circuits has received considerable attention. Therefore the formulas and estimating curves given in this paper may be of interest.

Formulas are developed for the inductance and capacitance to neutral per phase and the approximate corona starting voltage of perfectly transposed multiple-conductor three-phase transmission lines having any number of conductors per phase.

For certain special arrangements of the conductors, curves are given for the 60-cycle reactance, capacity susceptance, and corona starting voltage. Throughout their practical range these curves show the effect of variations in conductor diameter, spacing between phases and between conductors of the same phase. Two, three, four, and five conductors per phase are considered.

A comparison is made of multiple and single-conductor circuits with respect to charging current, voltage at no load, power which can be carried with the same voltage drop, and stability. (Pamphlet copies not available.)

# The Solution of Circuits Subjected to Traveling Waves

By
H. L. Rorden[12]

THE EFFECT of traveling waves upon terminal apparatus usually is most easily solved by means of Heaviside's operational calculus. Solutions have been given previously for various combinations of impedances that may be encountered in service, by considering such impedances to be contained in simple circuits. These are intended to approximate the general conditions of a transmission system. However, a purely mathematical analysis of such an involved nature often is looked upon skeptically and experimental variation of such calculation therefore is valuable.

It is the major purpose of this paper to illustrate the accuracy with which mathematical solutions of traveling wave theory are substantiated by test results. For this purpose a transmission about 2 miles long was used, this line consisting of parallel conductors placed 8 ft. apart and forming a loop so that both ends terminated at the laboratory where both the lightning generator and the cathode ray oscillograph were located. Various other arrangements were used including the direct application of the lightning waves to impedances and transformers.

Much valuable information has been obtained relative to the wave shape and other peculiarities of traveling waves. Many irregularities exist in these waves, but generally the waves may be reproduced to a sufficient degree of accuracy that their effect may be determined both analytically and experimentally. It was found that in general the test results checked the calculations very precisely. The relative importance of the various factors affecting traveling waves also are discussed, and it is pointed out that certain of these may be neglected. (Pamphlet copies not available.)

# Corona Limit, Transmission Characteristics, and Method of Loading Multiple Conductor Lines for Very High Voltages

By
C. A. Boddie[13]

THE OBJECTS of this paper are to discuss a simple and practical method by which the present transmission voltages may be increased greatly and to point out a method of avoiding the detrimental effects of the immense charging currents attendant on the use of very high voltages. The most formidable natural limitation which prevents raising line voltages is the formation of corona, and the paper is concerned chiefly with the overcoming of this limitation. This may be accomplished by the proper method of increasing conductor diameter and using multiple conductors. The conclusions brought out by this paper are as follows:

Transmission lines may be built for considerably higher voltage than those at present used, and the same economies available through the use of higher voltages apply to voltages above 220 kv. as apply below that value. No very serious difficulties may be expected in going to the higher voltages. Multiple conductor lines lend themselves naturally to use at very high voltages, and line charging currents may be taken care of easily by introducing air gaps in the raising and lowering transformers or by use of properly designed loading coils. Also, loading coils assist greatly in switching.

When large blocks of power are to be transmitted it is always most economical to push the line voltage up to the point where a single circuit will transmit all the power. This may always be done however great the power. The question of duplicate lines as affecting the continuity of service may in some cases tend to modify this conclusion, but in general the fewest possible number of circuits gives the most economical system. Improvement in the methods of operating large three phase lines will minimize the necessity for spares and emphasize the foregoing conclusion. (Pamphlet copies not available.)

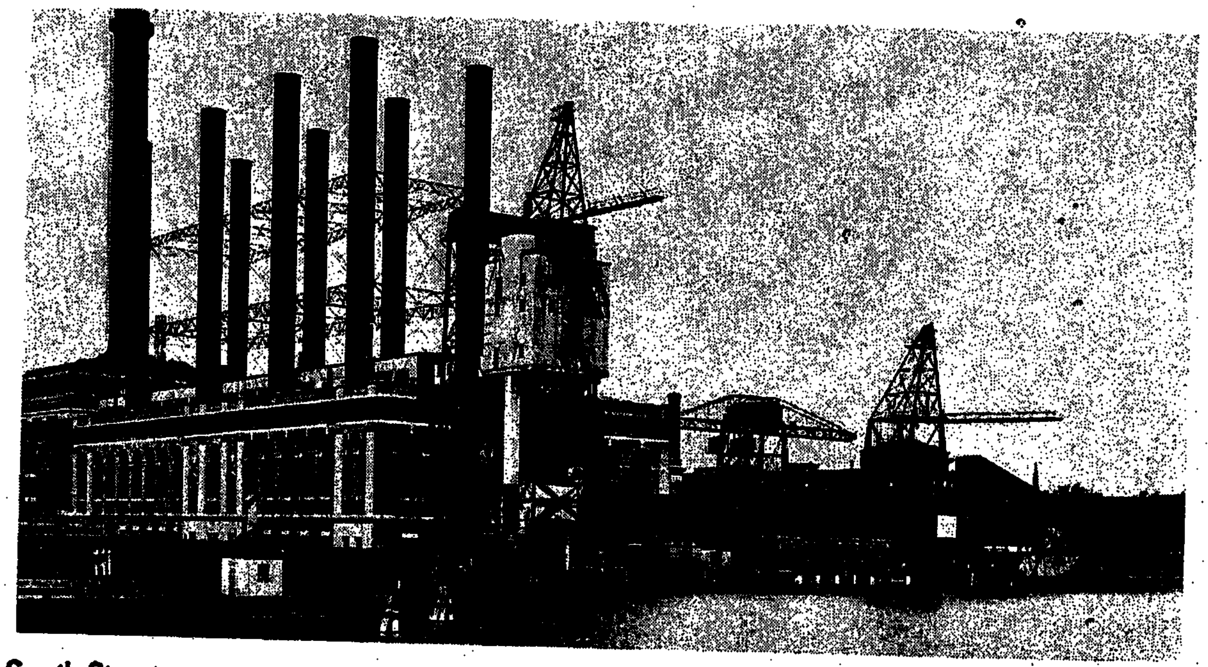
# North Eastern District to Meet at Providence

THE EIGHTH annual meeting of the North Eastern District of the A.I.E.E. will be held at Providence, Rhode Island, May 4–7, 1932, with headquarters at the Providence Biltmore Hotel. The committee has arranged an attractive program consisting of four technical sessions, inspection trips, a banquet, entertainment features, and a special program for the ladies. Another important feature of the meeting will be the student program scheduled for Friday, May 6. The technical sessions cover a variety of subjects. There will be a symposium on traffic control, a session arranged by the committee on electrical machinery, one by the committee on power transmission and distribution, and a session on selected subjects.

Providence, the capital of Rhode Island and the southern gateway to New England, enjoys exceptional shipping facilities to all parts of the world. Situated at the head of Narragansett Bay, 30 miles from the ocean, it occupies a strategic position as a port for both foreign and domestic commerce as well as a point of inland distribution; it is the second largest oil distributing port on the Atlantic seaboard. The city, itself, has a population of approximately 350,000, and within 15 miles of the city hall there are more than 700,000 inhabitants. The community enjoys 59 parks and playgrounds, the Roger Williams Park with its chain of lakes being considered one of the most beautiful parks in the country.

Providence is the home of Brown University established in 1664 and seventh in age among American colleges with an enrollment of approximately 2,200 students and a faculty of 200. Pembroke College for women is a part of the university. Providence College, the Rhode Island College of Education, the R. I. School of Design, and the R. I. College of Pharmacy all are located here. R. I. State College is at Kingston.

Industrially, Providence ranks high; it is the center of a state which has 55.1 per cent of its workers engaged in machine trades. The Brown and Sharpe Mfg. Co., makers of tools, the Nicholson File Co., American Screw Co., and Gorham Mfg. Co., makers of sterling silverware, all located in this city, are the largest in the world in their respective fields. The rubber industry also has good representation by seven large plants producing rubber footwear, medical goods, and novelties. Some of the largest plants of the U. S. Rubber Company are located here.



South Street generating station of the Narragansett Electric Company, Providence, one of the largest steam plants in New England. The installed generating capacity is 225,000 hp.

The Narragansett Electric Company, largest unit in the New England Power Association, serves most of the entire central and southern sections of the state, the southern part being served through a subsidiary company, the South County Public Service Company. The Blackstone Valley Gas and Electric Company serves the northern section and the Newport Electric Corporation the islands of Rhode Island and Conanicut. A network of transmission lines, steam and hydroelectric stations give to Rhode Island the benefit of an abundant supply of electric current. The Providence Gas Company established in 1848 serves about 82,000 customers in Providence and suburbs.

### ENTERTAINMENT FEATURES

Wednesday night will witness the "Gathering of the Clans." Provision will be made for informal get-togethers and reunions, card tables will be available, and supper dancing may be enjoyed in the Venetian Room of the Providence Biltmore Hotel.

Sock and Buskin, the dramatic organization of Brown University, is endeavoring to arrange a performance on Friday evening for the Institute members and ladies.

To the golf playing members there will be available the facilities of the Wannamoisett Country Club, a ranking course over which the Professional Golfer's Association in 1931 played off their championship. Tennis facilities will also be provided.

### BANQUET

The banquet will be held Thursday evening in the main ballroom of the Biltmore. Prof. William H. Kenerson of the mechanical engineering department of Brown University will act as toastmaster and William S. Lee, junior past-president of the Institute, will be the speaker of the evening. Both President C. E. Skinner and Vice-President I. E. Moultrop will address the meeting, and the District prizes awarded for papers given in 1931 will be presented. At the conclusion of these ceremonies there will be dancing until 1:00 a.m.

### LADIES' ENTERTAINMENT

The committee for the entertainment of the ladies has prepared what should be an interesting program. It is planned to spend one afternoon in colonial Rhode Island, a large share of which still maintains its original appearance. This will be rounded out with a tea in the historic mansion now housing the Handicraft Club. A luncheon and bridge at one of the city or nearby country clubs also is contemplated. Trips to Roger Williams Park and other points of local interest will be arranged. Golf courses and tennis courts will be made available to all ladies interested in those departments of sport.

Inspection Trips

Inspection trips are scheduled on the program for Thursday afternoon and Saturday morning. In addition, a special trip for the students is being arranged for Friday afternoon.

Full details of all trips will be announced later and posted on the bulletin board. Among the places of interest which may be visited are a generating station and substations of the Narragansett Electric Company and the Gorham Manufacturing Company. The engineering laboratories of Brown University will also be open for inspection. Several other trips also are being arranged.

Registration

All who plan to attend the meeting should register in advance by mail. A card for this purpose will be sent to all members of Districts 1 and 3 before the meeting. Members should complete their registration after arrival at the meeting so as not to miss the opening session. There will be a meeting fee of one dollar for members and fifty cents for students.

All who register in advance will be sent a road map of Rhode Island and a map of the downtown section of Providence showing headquarters and convenient parking and garage facilities.

Hotel reservations should be made by writing directly to the hotel preferred. Rates for the headquarters hotel, Providence Biltmore, as well as several other recommended hotels are given in the accompanying table.

## Technical Program

Abstracts of all papers to be presented at the meeting are given on adjoining pages. Pamphlet copies of these papers are not available.

All technical sessions and the opening of the meeting will be held at the Providence Biltmore Hotel. Breakfast meetings will be announced on the bulletin board near registration headquarters and will be held daily for authors and chairmen of the technical sessions scheduled for the day.

### Wednesday, May 4

**9:00 a.m.—Registration**

**9:30 a.m.—Opening Session**

Opening address—I. E. Moultrop, vice-president, North Eastern District, A.I.E.E.

Welcoming remarks—James E. Dunne, mayor of Providence

Greetings—Leighton T. Bohl, president of Providence Engineering Societies

**Selected Subjects—Prof. V. Bush, *chairman***

Parallel Type Inverter, F. N. Tompkins, Brown University

Engineering Features of Phanotron Tubes, H. C. Steiner, A. C. Gable, and H. T. Maser, General Electric Co.

Subharmonic Frequencies Produced in Non-Linear Systems, W. M. Goodhue, Harvard University

A General Theory of Systems of Electric and Magnetic Units, V. Karapetoff, Cornell University

A Proposal to Abolish the Absolute Electrical Unit Systems, E. Weber, Brooklyn Polytechnic Institute

**2:00 p.m.—Electrical Machinery—P. L. Alger, *chairman***

Performance Characteristics of Induction Motors, C. G. Veinott, Westinghouse Electric & Mfg. Co.

Stray Load Loss in Polyphase Induction Motors, C. J. Koch, General Electric Co.

Torque-Angle Characteristics of Synchronous Machines Following System Disturbances, S. B. Crary and M. L. Waring, General Electric Co.

Field Tests to Determine the Damping Characteristics of Synchronous Generators, F. A. Hamilton, General Electric Co.

Design of Capacitor Motors for Balanced Operation, P. H. Trickey, Westinghouse Electric & Mfg. Co.

**8:00 p.m.—Informal Reception**

### Thursday, May 5

**9:00 a.m.—Symposium on Traffic Control—H. M. Turner, *chairman***

Address: The Broader Aspects of Traffic Control, E. P. Goodrich, president, Traffic Institute

The Flexible Progressive Traffic Signal System, H. I. Turner, Eagle Signal Corp.

Electromatic Traffic Dispatching System, H. A. Haugh, Jr., Automatic Signal Corp.

Recent Developments in Traffic Control, H. W. Vickery and V. W. Leonard, General Electric Co.

Traffic Flow Regulator, C. H. Bissell and J. G. Hummel, Crouse-Hinds Co.

**12:00 m.—District Executive Committee Luncheon**

**2:00 p.m.—Inspection Trips**

**6:00 p.m.—Banquet**

### Friday, May 6

**9:00 a.m.—Student Technical Session**

Address—William S. Lee, junior past-president, A.I.E.E.

Awarding of Prizes

**12:00 m.—Luncheon Conference of Counselors and Delegates**

**2:00 p.m.—Student Inspection Trip**

**2:00 p.m.—Transmission—P. H. Chase, *chairman***

Double Conductors for Transmission Lines, H. B. Dwight and E. B. Farmer, Massachusetts Institute of Technology

Three Phase Multiple Conductor Circuits, Edith Clarke, General Electric Co.

The Solution of Circuits Subjected to Traveling Waves, H. L. Rorden, General Electric Co.

Corona Limit, Transmission Characteristics and Method of Loading Multiple Conductor Lines Designed to Operate at Very High Voltage, C. A. Boddie, Boddie Electro Physical Labs.

**7:30 p.m.—Entertainment Feature**
**(To be announced at the meeting)**

### Saturday, May 7

Meeting rooms have been arranged for continued sessions of any part of the technical program.

The local committee is planning an all-day trip, details of which will be announced later.

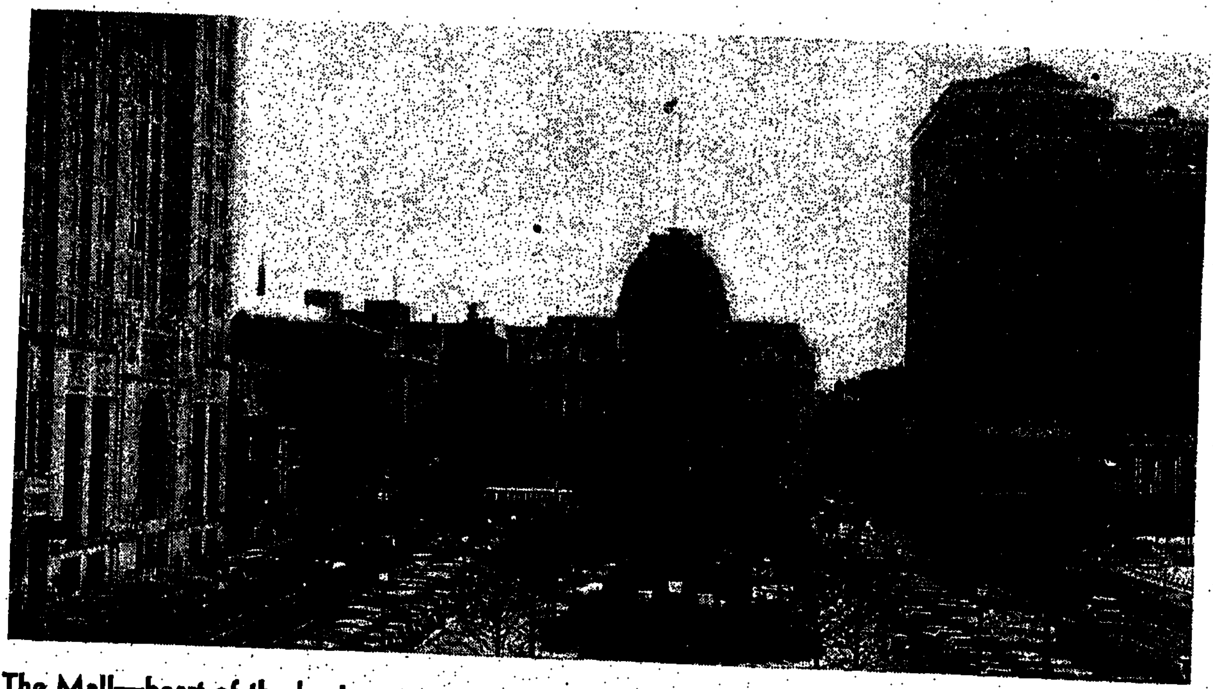
Rules on Presenting and Discussing Papers

At the technical sessions papers will be presented in abstract, ten minutes being allowed for each paper unless otherwise arranged or the presiding officer meets with the authors preceding the session to arrange the order of presentation and allotment of time for papers and discussion.

Any member is free to discuss any paper when the meeting is thrown open for general discussion. Usually five minutes is allowed to each discusser. When a member signifies desire to discuss papers on other subjects or groups he shall be permitted a five-minute period for each subject or group.

It is preferable that a member who wishes to discuss a paper give his name before hand to the presiding officer of the session at which the paper is to be presented. Copies of discussion prepared in advance should be left with the presiding officer.

Each discusser is to step to the front of



**The Mall—heart of the business section of Providence—looking toward the city hall from the steps of the Federal Building. The Providence Biltmore Hotel is on the right, the Union station being slightly further to the right**

the room and announce, so that all may hear his name and professional affiliations.

### Committees

**District Meeting**—I. E. Moultrop, *chairman*, vice-president, North Eastern Dist.; A. C. Stevens, secretary-treasurer, North Eastern Dist.; C. W. Henderson, chairman, Student Counselors, North Eastern Dist.; O. W. Briden, R. W. Graham, W. S. Maddocks, J. P. McCann, R. G. Warner, and F. C. Young.

**Local**—W. S. Maddocks, *chairman;* O. W. Briden, *secretary-treasurer;* R. W. Herrick, Mrs. R. W. Herrick, J. W. Keeney, L. P. Kenneally, and J. C. B. Washburn.

**Hotels and Registration**—O. W. Briden, *chairman;* R. W. Allen, L. P. Breault, A. S. Kirk, E. E. Nelson, R. C. Patton, O. E. Sawyer, F. N. Tompkins, and R. J. Underwood.

**Finance**—J. W. Keeney, *chairman;* W. W. Broadbent, and O. W. Briden.

**Inspection Trips and Transportation**—J. C. B. Washburn, *chairman;* P. W. Browers, P. L. Carroll, E. B. Curdts, R. W. Eaton, L. E. Fogg, J. E. Hall, C. H. Parker, and G. U. Parks.

**Sports, Entertainment, and Banquet**—R. W. Herrick, *chairman;* E. S. Esty, M. V. Gardner, I. W. Knight, J. J. O'Brien, W. C. Slade, T. G. Webber, and J. W. Young.

**Student Program**—C. W. Henderson, *chairman;* W. B. Hall, and L. W. Hitchcock.

**Publicity**—L. P. Kenneally, *chairman.*

**Ladies Entertainment**—Mrs. R. W. Herrick, *chairman;* Mrs. R. W. Eaton, Mrs. W. S. Maddocks, Mrs. W. C. Slade, and Mrs. J. W. Young.

| Hotel | Single | Double |
|---|---|---|
| Providence Biltmore | $3.50–$7.00 | $5.50–$10.00 |
| (With bath and shower) | $5.00–$8.00 | $7.00–$12.00 |
| Narragansett | $2.50* | $4.00* |
| | $3.00–$3.50 | $4.50–$5.00 |
| Crown | $2.00* | $4.00* |
| | $3.00 | $6.00 |
| Wayland Manor (Family Hotel) | $3.50 | $5.00 |
| Apartments, 3 or 4 persons, $2.50 per person | | |

* Rooms without bath.

# Great Lakes District
## Milwaukee Meeting Exceeds Expectations

As a fitting tribute to the various committees that planned and handled the meeting of the Great Lakes District (No. 5) held at the Pfister Hotel in Milwaukee March 14–16, the attendance and participation in the meeting activities exceeded even the fondest expectations of those in charge of the work. The whole program of activity for the meeting was well conceived, and organized for the greatest convenience of those attending. Technical sessions were held only in the forenoons, Monday, Tuesday, and Wednesday, with the single exception of the student technical session which was held Monday afternoon. An attractive and carefully managed program of inspection trips provided those in attendance with afternoon activities which served as recreation as well as to acquaint the participants with the interesting features of Milwaukee industries. The popularity of this program was emphatically attested to by the registration of 552 members, Enrolled Students, and guests.

With credit to T. N. Lacy of Detroit, Mich., and to A. G. Dewars of Minneapolis, Minn., respectively vice-president and secretary for the Great Lakes District, for the coordination of District activities in connection with the meeting, full credit for the untiring prosecution of the details so essential to meeting success, goes to F. A. Kartak, dean of engineering of Marquette University, Milwaukee, vice-chairman of the District meeting committee, and to the committee organization which functioned under his direction. The general committee, in addition to those already mentioned, included C. C. Knipmeyer of Terre Haute, Ind., student counselor for the Great Lakes District; J. F. H. Douglas, Fraser Jeffrey, C. H. Krueger, and E. U. Lasson, of Milwaukee, Wis.; F. R. Innes and F. H. Lane, of Chicago, Ill.; N. H. Blume and L. C. Larson, of Madison, Wis.; and C. E. Skroder of Urbana, Ill.

### Technical Sessions

The Milwaukee technical program consisted of sixteen papers divided among three sessions held one each morning. For the most part these sessions were operated on a strict schedule so as to balance the time between presentation and resulting discussion. This program control contributed to the effectiveness of the sessions, all of which were heavily attended (as high as 300 persons per session). In so far as possible papers were grouped on the program according to their subject matter and expected appeal.

One effort which undoubtedly contributed in an important way to the smooth and effective handling of the various technical sessions was the holding each morning, preceding the session, of a breakfast meeting presided over by the chairman of that day's session and attended by all persons involved in the presentation of papers for that session. At these informal conferences last minute details involving the coordination of presentation and discussion were worked out to mutual satisfaction, and any special contingencies taken care of, all to the benefit of the session itself. The technical program was under the direction of Prof. J. F. H. Douglas, whose committee comprised L. R. Mapes and H. E. Wulfing, of Chicago, Ill., E. Bennett of Madison, Wis., B. H. Clingerman of Minneapolis, Minn., G. E. Lewis of Ann Arbor, Mich., and S. H. Mortensen and G. G. Post of Milwaukee, Wis.

### Student Program

The student program, in addition to active student participation in all meeting activities, included a Monday morning executive session of the student activities committee under the chairmanship of Prof. C. C. Knipmeyer, student counselor for the Great Lakes District. At that session there was 100 per cent attendance of Student Branch chairmen from the sixteen Branches in the district. Each chairman gave a report covering the year's work of his branch, and also outlined plans and problems involved in future activities. An open forum discussion resulted in a highly desirable interchange of ideas.

The student technical session held Monday afternoon was attended by 225 Enrolled Students, comprising an excellent representation from each of the District's sixteen Branches. Ten excellent technical papers prepared by nineteen student authors were presented during the afternoon's session. Interest was so intense that all present remained throughout the entire afternoon for the presentation of the whole group of papers, maintaining the closest attention throughout the session. The 150 mimeographed copies of each of the ten papers that were available for distribution at the meeting failed to meet the demand. Papers presented included the following:

1. The Electron Tube in the Modern World, F. M. Deerhake, University of Illinois.
2. Opportunities in Home Lighting, D. W. Marchant, University of Iowa.
3. Low Voltage A-C. Distribution Networks, O. J. DeBever, Lewis Institute.
4. Magnetic Tests of Cold Rolled Steel, Grey Cast Iron and Chrome-Nickel Cast Iron at High Flux Densities, E. Halbach, H. Van-Pietersom, C. R. Dernbach, C. G. Post, C. R. Mikolic, M. J. Auchter, R. G. Klein, and H. A. Trimborn, Marquette University.
5. Distribution of Electricity for Lighting of Buildings, L. Zanoff, University of Michigan.
6. Resonance in a Non-Linear Circuit, R. T. Bozak, School of Engineering of Milwaukee.
7. An Experimental Study of Induction Motor Losses, E. S. Loye, and L. A. Rovelshy, University of Minnesota.
8. Television, an Invention in the Making, E. M. Purcell, Purdue University.
9. Dibutyl Phthalate as a Substitute for Transformer Oil, J. W. Niemi, and J. H. Montgomery, Rose Polytechnic Institute.
10. Rectilinear Graphs, H. E. Grant, University of Wisconsin.

Monday evening a special student dinner was served at the Marquette Union, followed by suitable brief addresses and a lively St. Patrick's celebration under the auspices of the local Student Branches. Prof. C. C. Knipmeyer in charge of student program, was ably assisted by E. W. Kane and V. M. Murray of Milwaukee.

### Entertainment Features

Active in supporting Milwaukee's reputation for hospitality, the various committees that promoted and handled the inspection trips, the women's activities, and the dinner-dance program provided those attending the meeting with more than they could do within the allotted time. These activities were well conceived and carefully and smoothly fitted into the general program for the Milwaukee meeting. Inspection trips, available each afternoon, embraced local industrial and municipal undertakings of a scope sufficiently wide to meet the desires of the most critical. Transportation was supplied by the local committee for trips *en masse* for the larger and more popular trips, and transportation for small parties wishing to make trips of a special character. This feature of the program was under the direction of W. F. Lent of Milwaukee, whose committee consisted of C. W. Kuhn, J. A. Potts, L. F. Reinhard, and R. C. Siegel, of Milwaukee.

Inspection trips included the plants of Allis-Chalmers Manufacturing Company, Falk Manufacturing Company, Cutler-Hammer Inc., Westinghouse Lamp Company, and the O. A. Smith Corporation; properties of The Milwaukee Electric Railway & Light Company and the Wisconsin Telephone Company; and the Milwaukee sewage disposal plant.

Activities planned for the women and carried out under the direction of Mrs. J. D. Ball of Milwaukee included shopping trips, sightseeing trips, and bridge and theater parties. Organized activities were supplemented by provisions to take care of special desires of smaller groups. Assisting Mrs. Ball were: Mrs. S. C. Fraser, Mrs. Fraser Jeffrey, Mrs. E. W. Kane, Mrs. F. A. Kartak, Mrs. V. M. Murray, Mrs. A. Simon, Mrs. C. H. Skinner, Mrs. R. B. Williamson, Mrs. S. H. Mortensen, and Mrs. E. W. Seeger.

A fitting climax to the entertainment side of the program was furnished by the informal dinner-dance held Tuesday evening under the direction of Prof. John D. Ball of Milwaukee, and his hard-working committee: F. A. Coffin, S. C. Fraser, J. A. Havlick, R. G. Lockell, O. W. A. Oetting, C. H. Skinner, Sam Snead, R. M. VanVleet, and C. T. Evans, all of Milwaukee and vicinity. Notably well done was the effort to make the dinner a true reflection of an old-time German festive affair in keeping with the best local custom, and those customs traditionally if not too accurately ascribed to Milwaukee. The German menu was more than most of those in attendance could decipher, but the result was voted a genuine success. Likewise the entertainment proved to be particularly well arranged, and was brought to a well conceived climax at the close of the dinner. The dinner entertainment features included the local and highly popular "Heidelberg Quartette," properly costumed and most popular when reflecting a German atmosphere; a "German street band"; two "sisters" in a Dutch wooden shoe dance; and subsequently in a song presentation Miss Kathleen Sauerwald, a contralto accompanied at the piano by her sister, whose beautiful presentations repeatedly "brought down the house" with round after round of enthusiastic applause. For the dancing subsequent to the meal, the "Electric Orchestra," electrical reproducing equipment functioning through a public address system set up for the occasion and operated under the engineering guidance of R. E. Deland and Sam Snead, admirably (and very economically) supplied selected dance numbers to supplement the efforts of "Heine's Band."

A registration exceeding expectations by 50 per cent was efficiently handled by J. U. Heuser and his committee: F. T. Coup, J. L. Defandorf, W. H. Fernholz, I. L. Illing, C. G. Matthews, and H. A. Bartlin. Mr. Heuser's committee was effectively assisted in registration work by a group of young women generously supplied by the Milwaukee Association of Commerce. The Pfister Hotel was exceptionally generous in making available without cost rooms and services for meeting purposes.

One of the features of the Milwaukee meeting was a policy of no registration fee either for members or students. The success of this policy, in spite of the heavy offering of inspection and entertainment activities, was made possible by the hard work of the finance committee under the direction of Fraser Jeffrey, of Milwaukee, and his committee: R. L. Dodd, P. B. Harwood, and H. L. Van Valkenburg, of Milwaukee; and K. A. Auty of Chicago, Ill. That the publicity efforts of R. R. Knoerr and his aid, J. H. Sobey, were effective was evidenced by the repeated attention given to the meeting by Milwaukee and other Wisconsin papers.

## Executive Committee Memorializes Leaders

Two long-active leaders in the affairs of the American Institute of Electrical Engineers, recently deceased, were memorialized by the executive committee of the Institute's board of directors at its regular meeting held at national headquarters March 9, 1932. Resolutions adopted giving official recognition to the valued services of former National Secretary F. L. Hutchinson are recorded in full on p. 227 of this issue; those recognizing the services of the late Dr. Harold Babbitt Smith, past-president of the Institute, follow:

WHEREAS: Through the death of Professor Harold B. Smith the American Institute of Electrical Engineers has lost one of its most active and influential members, a noted leader who had rendered valuable services as a member of many committees, a director, a vice-president, and as president,

WHEREAS: His keen interest in District, Section, and Branch activities and his success in encouraging their development contributed much to the growth and influence of the Institute,

WHEREAS: His vigorous leadership in electrical engineering education and research, his ability to correlate developments in theory and practise, his deep interest in the progress of his students and former students, as well as his quiet, persistent enthusiasm for the development of the entire electrical engineering field won the high respect of many friends, be it, therefore,

RESOLVED: That the executive committee on behalf of the membership hereby expresses its sense of the great loss which the Institute and the entire engineering profession have sustained, and be it further

RESOLVED: That these resolutions be entered in the minutes and that a copy be transmitted to members of his family.

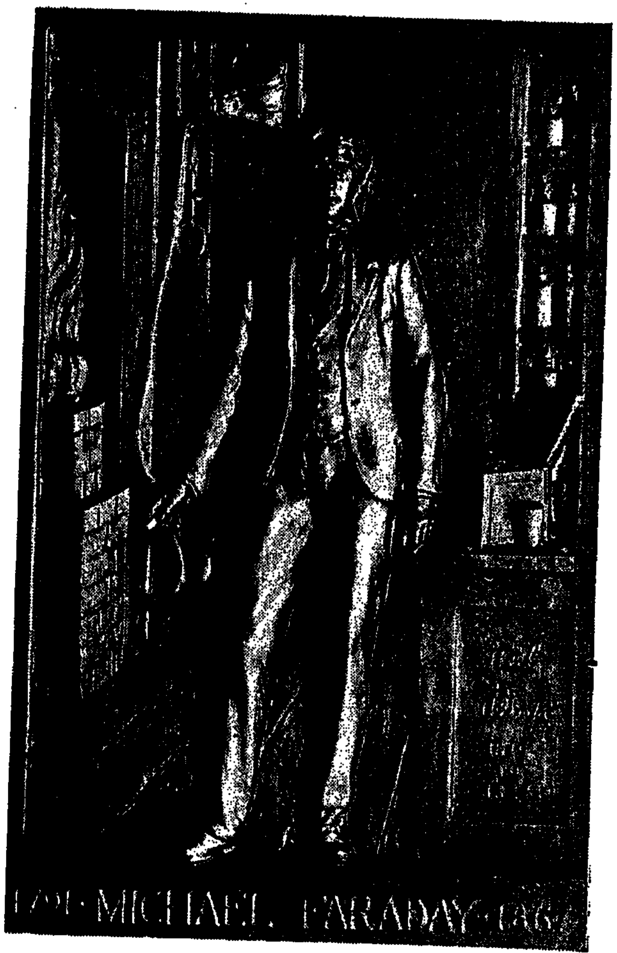
**American Welding Society to Meet in April.**—A tentative program has been announced for the annual meeting of the American Welding Society to be held in the Engineering Societies Building, 33 West 39th Street, New York, N. Y., April 27–29, 1932. Five technical sessions including 23 papers, covering a wide variety of subjects, have been scheduled. In addition there will be a business session and meetings of the board of directors, the structural steel welding committee, and the American Bureau of Welding. The eleventh annual dinner which will be arranged as a stag affair is scheduled for the evening of April 28.

## Faraday Plaque Given to the Institute

Sir Robert A. Hadfield, London, England, has presented to the Institute a bronze plaque of Michael Faraday, having as a background the workshop in which Faraday performed his experiments on steels and alloys. On the right is shown a box, labeled by Faraday, and in which were found 79 of his specimens of steel and alloy steel, while on the left is shown the famous "blast" furnace used by Faraday. The plaque has been accepted by the board of directors of the Institute.

It measures 13 x 8$^1/_2$ in., and is a replica of that prepared by F. J. Halnon, a sculpture of some note in London, and used as the basis for the frontispiece of a book "Faraday and His Metallurgical Researches" recently written by Sir Robert Hadfield. This book, having special reference to the development of alloy steel, has been prepared by a man who is himself not only a disciple of Faraday, but also a metallurgist through his numerous researches contributing much to the development of magnetic and other steels.

The story deals with the work of Michael Faraday during the period between 1819 and 1824 when he confined his investigations to the realm of metallurgy. This was his first research and led to others which he later made in chemistry and electricity. In addition to the historical matter in the book, much technical information is included, so that a careful study may be found to be of practical importance. Considerable research and investigation were undertaken in preparing the text, and the author has combined these results with the historical data in a volume most pleasing and interesting to read. The book, 329 pages in length and carefully illustrated, is published by Chapman and Hall, Ltd., London, England.



# Summarized Review of Some Winter Convention Discussions

PRINCIPAL discussions of winter convention papers are summarized herewith. The papers to which these discussions refer were abstracted in ELECTRICAL ENGINEERING for January 1932, p. 39–49 and February 1932, p. 130–2, excepting only the papers given more complete treatment in these same issues; additional articles based upon these papers are being presented in subsequent issues.

Only discussion submitted in writing in accordance with governing A.I.E.E. rules is summarized. Complete discussion together with all approved papers will be published in the TRANSACTIONS.

## Protective Devices

### A NEW HIGH SPEED DISTANCE RELAY

J. H. Neher (Philadelphia, Pa.) discussed this paper and pointed out that no assurance is offered that the relay will operate on a high-speed basis when three-phase flashovers of low arc impedance occur near the relay. He believed the problem could not be solved until there is developed a directional element which will give high-speed operation under this condition.

O. C. Traver (Philadelphia, Pa.) in his discussion of this subject remarked that the modified impedance relay described in the paper was a distinct step in advance over previous impedance relays. He agreed that, if it is to work selectively, the reactance relay must be provided with greater discriminating power than the impedance type. On the other hand he believed that the straight impedance type, and to a lesser extent the impedance-reactance relay, was apt to be too conservative and neglect its duty, so reactance would be the preferable function.

W. A. Hillebrand (Barberton, Ohio) inquired, in connection with the use of the series condenser as indicated in Fig. 6 of the paper, if there would be any inherent objection to using a bushing or other potential device instead of the series condenser to obtain the lead angle.

R. D. Evans (East Pittsburgh, Pa.) in his discussion summed up conditions which prevail on modern power systems. He explained that these conditions create a need for the modified impedance relay described in the paper. This device while still retaining its characteristic as an impedance relay minimizes the effects of fault resistance.

### OIL CIRCUIT BREAKERS

Philip Sporn (New York, N. Y.) reported that during the past year great improvement in breaker and system performance was obtained by the use of both the deion grid and oil blast explosion chamber breakers. Another point which he stressed was the inadequacy of the present standard duty cycle. In view of recent developments and tests, manufacturers were urged to offer users of oil circuit breakers a duty cycle which would be more consistent with actual power system operation.

J. Slepian (East Pittsburgh, Pa.) discussed "The Theory of Oil Blast Circuit Breakers" and disputed several of the principles. He explained the useful function of an arc by considering what would happen should it not form spontaneously when separating a pair of contacts in a power circuit. The hydromechanical principles also were analyzed as was some of the data; the discusser contended that some data given in the paper did not support the author's claims.

E. J. Poitras (Philadelphia, Pa.) answered several questions raised in discussion of this subject. He explained that the first group of tests was made where rates of rise of recovery voltage above 500 volts per microsec. were not available. They were not made with a view to completely filling in the graph and so no effort was made to obtain abnormally low oil velocities. When plotted in terms of recovery voltage rate and oil velocity, each parameter covering a reasonably wide range showed the excellent correlation of these parameters with success or failure to clear the circuit at the first current zero. He further explained that while it would have been desirable to make tests at all oil velocities and recovery rates and for all different generator voltages, such were not deemed advisable because, in circuit interruption, recovery voltage rate rather than nominal voltage is unquestionably predominant, and the making of many tests is expensive.

W. K. Rankin (Philadelphia, Pa.) in his remarks referred to the theory of deionization by turbulence as compared with the closing of the arc path at current zero by a fluid dielectric. He believes that the former theory bore some weight, even though in the case of an arc drawn to considerable length in a tank of oil other theories have been proposed. However, when considering a maximum of 1 in. contact separation, and recovery voltage rates of rise from 135 to 800 volts per microsec. across the contacts, tests have proved that the gaseous dielectric would not prevent breakdown; therefore he concludes that oil which does have sufficient dielectric strength is inserted between the contacts.

F. H. Stoppelman read a discussion on this subject prepared by C. L. Fortescue (East Pittsburgh, Pa.) which referred to early experimental work. The results indicated that something besides length was required to quench an arc. In fact, as shown in the papers by Messrs. Browne, Van Sickle, and Leeds, the requirement now is a turbulent gas stream across the path of the arc. He believed data on the oil blast principle would be explained just as well by the fact that the gas formation and its turbulency are functions of the velocity by which the oil is introduced into the ionized path between electrodes.

J. B. MacNeill (East Pittsburgh, Pa.) in his discussion of circuit breakers drew attention to the general improvement made in these interrupting devices and the reduction of the hazards which result from the use of oil in these devices. He believes the oil blast device operating on one end of the arc to be most effective for low voltages; however, for high voltages he questions its ability to produce effective results, and advocates the deion grid principle of interposing successive increments of arc rupturing ability as the arc is lengthened by the gases which have formed passing transversely across the full arc length.

T. E. Browne, Jr. (East Pittsburgh, Pa.) discussed this subject, in his conclusion submitting three reasons why it was impossible for him to agree with Mr. Prince's conclusions. One of these reasons was that as yet no detailed picture capable of withstanding critical analysis has been presented of the mechanics by which the oil film may be formed.

### EXTINCTION OF A-C. ARCS

R. C. Van Sickle discussed this subject and pointed out certain differences between the functioning of the experimental structure described by Mr. Browne and the deion grids, which differences should be realized when comparing results as they might explain why the recovery voltage gradients of deion grids are higher.

J. J. Torok (East Pittsburgh, Pa.) discussed this subject and described an experiment on extinguishing arcs in fiber tubes wherein droplets in the tube materially increased the surface on which ions could be collected. He found that the author's treatment of the expulsion fuse substantiated the theory of the turbulent gases.

W. A. Hillebrand (Barberton, Ohio) discussed this subject also and briefly described the Poulsen radio arc transmitter. He believes that the curves presented by Mr. Browne confirm earlier experience with this transmitter. He also offered as a possible contributing cause for the difference between the curves of Fig. 6 for oxygen and nitrogen, the fact that free electrons can exist in an atmosphere of nitrogen but not in an atmosphere of oxygen.

## Instruments and Measurements

### A POWER FACTOR BRIDGE OF HIGH SENSITIVITY

Perry A. Borden (Waterbury, Conn.) discussed this subject and described a method of balancing out induced voltages in the galvanometer coil by the use of a neutral inductance in the field circuit; this would appear to remove one of the objectionable features of the electrodynamic galvanometer.

J. C. Balsbaugh (Cambridge A, Mass.) discussed this subject and told of a modified Schering bridge using an amplifier in the detector circuit offering a precision in power factor measurement of $10^{-6}$, this modified form having been constructed at the Massachusetts Institute of Technology. When all the factors affecting the power factor precision of the bridge have been fully investigated, it is planned to make formal publication of this research. In conclusion, the discusser pointed out that there were no calculations or tests giving the sensitivity or precision of the bridge described in the paper.

Leo J. Berberich (Paulsboro, N. J.) discussed the high accuracy of power factor measurements possible when using a bridge of the type described in the paper. He gave data which showed the excellent agreement found between the computed power factor of the standard and the power factor as measured by the bridges of the type described by Doctor Kouwenhoven. It evidenced also close agreement between the two bridges used at the Johns Hopkins University.

S. K. Waldorf (Baltimore, Md.) analyzed several cases mentioned in this paper, commenting upon the net effect of a reduction of specimen size, high humidity conditions, and double shielding on the transformer used in the galvanometer circuit. He also warned those who have occasion to build small high voltage air capacitors against the use of small plate dimensions, and a spacing of not less than five millimeters was suggested.

One of the points considered by R. P. Siskind (Cambridge, Mass.) in his discussion of this paper was the possible effect upon the accuracy of the bridge from the presence of harmonics. He explained that when a potential sufficiently high was applied to the test specimen it would cause ionization producing third and other harmonics. It was believed that these might cause some small error to exist in the bridge.

### INSTRUMENT SPRINGS

A. B. Smith (Chicago, Ill.) discussed the use of the grid glow micrometer mentioned in the paper. He told of having previously compared the use for detection purposes of a 2-watt, 110-volt neon lamp with a radio headset. The comparison revealed advantages in the use of the receiver, such as sensitivity when the resistance was greater than 59 megohms. Also with the use of a receiver for detection, the eye is left free for other observations.

J. R. Townsend (New York) discussed the means of stabilizing instrument springs and referred to the work of Sayre, Dalby, Scott, and Abbott. He believes the method of heating above the service temperature as suggested by Messrs. Carson and MacGahan, to be a good one.

### AN AUTOMATIC OSCILLOGRAPH

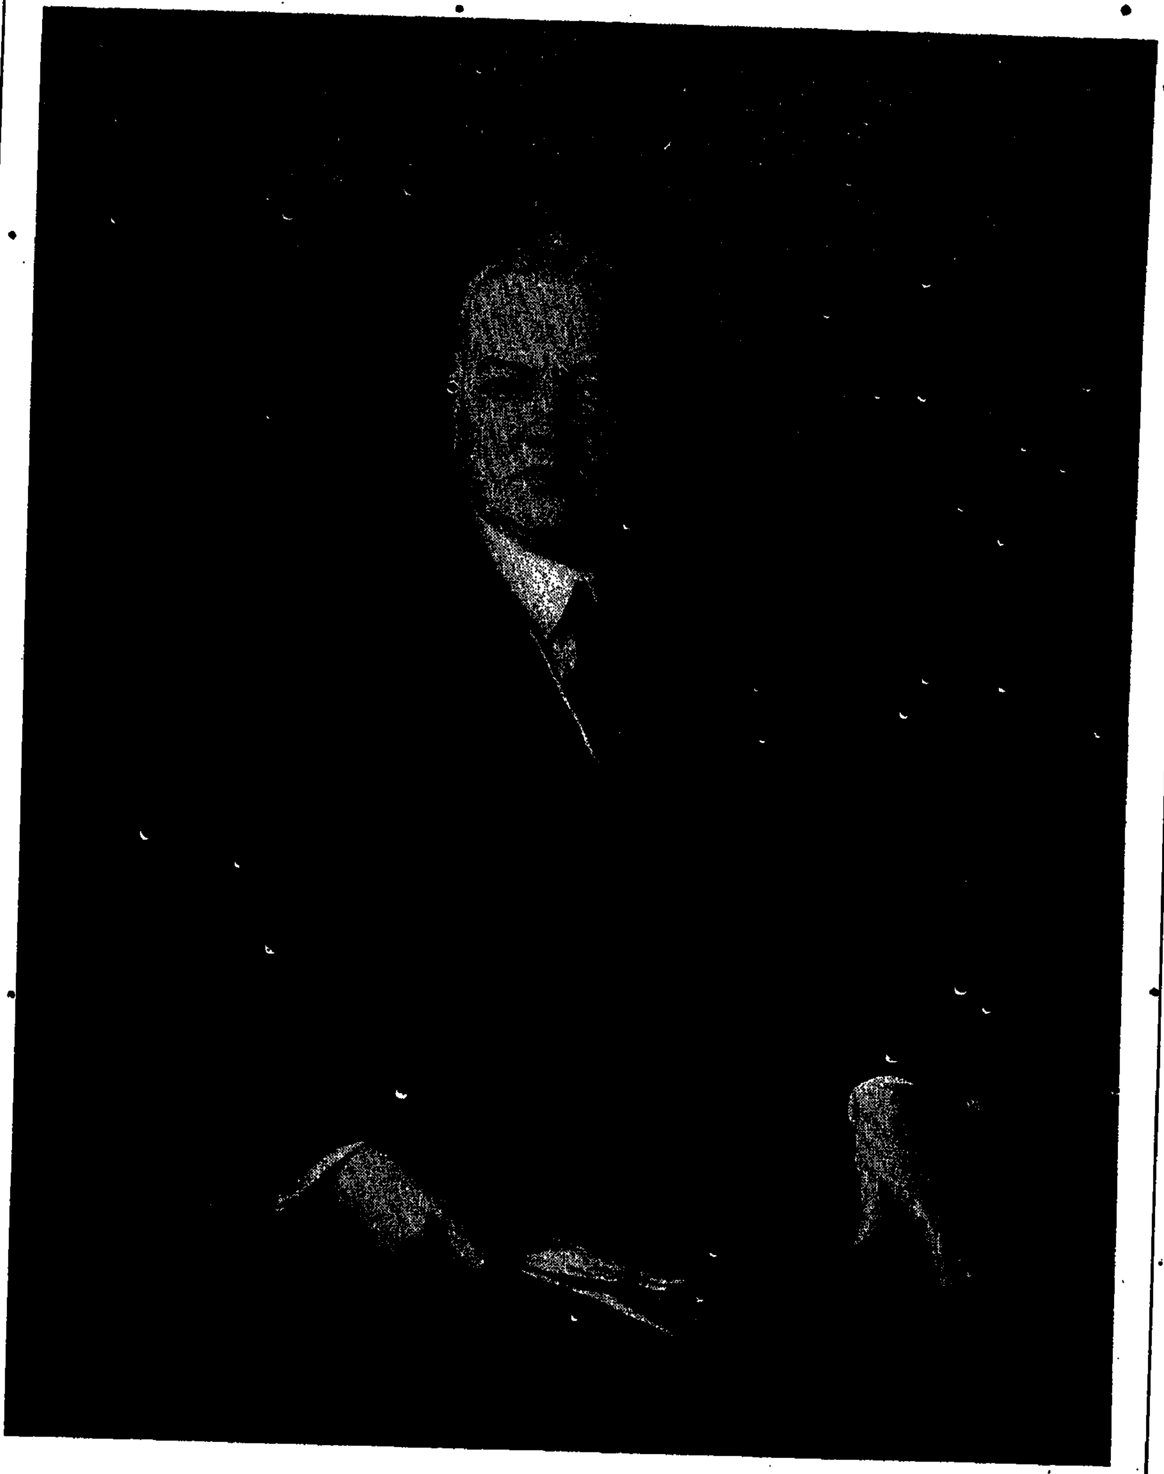
Wm. G. Walker (Philadelphia, Pa.) told of experience at Plymouth Meeting Substation with a development model and later a commercial model of the oscillograph described in the paper. Several suggestions advanced by the men maintaining the development model were incorporated in the commercial model. Out of 63 operations recorded during an interval of 160 days, no records were lost through failure of the instrument to function.

### THE PHOTOELECTRIC RECORDER

P. E. Quiss (Lynn, Mass.) discussed this subject and emphasized the sensitivity and quick starting features of this apparatus which enable it to record values heretofore measured only by the use of indicating instruments.

C. W. Mayott (Hartford, Conn.) explained that the photoelectric recorder had been installed in the load supervising office at Hartford. It has been in service for

## The Engineer President



WITH SIMPLE CEREMONY this de Laszlo painting of Herbert Hoover—Honorary Member of the civil, mining, mechanical, and electrical engineering societies and past-president of the American Institute of Mining and Metallurgical Engineers—was unveiled February 15, 1932, before a meeting of the United Engineering Trustees, Inc., held in the Engineering Societies Building at 25–33 West 39th Street, New York, N. Y. To this meeting were invited the presidents, vice-presidents, secretaries, and boards of directors of the four national engineering societies, and a few other especially prominent engineers and organization representatives. As chairman of the Hoover Medal Board of Award, representing the four engineering societies, Dr. Gano Dunn, past-president of the Institute, delivered the portrait to H. A. Kidder, Fellow of the Institute and president of the United Engineering Trustees, the organization which will be the official custodian of the portrait.

President Hoover kindly sat for the painting during Christmas week, 1931, in response to a request made jointly by the four national engineering societies. The portrait was arranged for at that time in order to take advantage of the presence in this country of the internationally known artist, Philip A. de Laszlo of London, England. The portrait of President Hoover, mounted in a valuable frame contributed by the artist, now is the joint property of the four engineering societies and is to be hung prominently on the east wall of the reading room of the Engineering Societies Library "where it can be seen by engineers and the public alike, and where it may constantly stir to pride and emulation the members of the engineering profession."

approximately a year and a half. During this time the only replacement required was the light source bulb. Frequency records were obtained in such detail as to be beyond the requirements of any present operating demands.

H. A. Rolnick (Philadelphia, Pa.) inquired regarding the smallest angular motion of the indicating element to which the recorder would respond, and whether or not it was dependent on the electrical circuit, the optical system, or both.

## Distribution Circuit Lightning Protection

Harold C. Dean (New York, N. Y.) expressed belief that the most important contribution made to the industry by the papers in this symposium was the proof offered that lightning arrester ground leads should be connected to the secondary neutral where the latter is adequately grounded; he advocated also the grounding of transformer cases to the secondary neutral. It was explained that those in the New York Edison Company have the philosophy that a known hazard is to be preferred to an unknown hazard, and they have adopted as a standard the grounding of all transformer cases.

A. H. Schirmer (New York, N. Y.) explained that the results obtained from Bell system tests indicated that for transformer protection an arrester should be placed between the primary and secondary. The arrester should have a current limiting element so designed that the voltage across the transformer windings would be held to a value slightly below the impulse strength of the transformer. This would hold to the lowest practical value the lightning voltage on the secondary caused by a surge on the primary, and no power voltages of considerable magnitude would appear between the secondary circuit and ground.

F. W. Peek (Pittsfield, Mass.) suggested that with an object to devising lightning tests the proper technical committees of the Institute should review present methods of testing. These tests were suggested as a supplement to the present tests and not to supersede them. This suggestion for consideration was made after years of experience with lightning tests on transformers in an effort to devise lightning proof transformers and also for making lightning tests on commercial transformers. These facts were mentioned to show that lightning tests are entirely practicable.

A. E. Silver (New York, N. Y.) called attention to the change in trend toward the objective of lightning protection. He explained that in the past, attention to the subject of lightning on distribution circuits seemed to have centered on the distribution transformer and what could be done to protect it rather than upon lightning effects on service. He commended the authors of the paper on the Philadelphia Electric system for moving the main objective of their studies from the distribution transformer to its effects upon service.

C. L. Fortescue (East Pittsburgh, Pa.) analyzed the proposed connection of the lightning arrester ground lead to the secondary neutral as advocated in the papers. He believes that the proposed connection assured much better protection to the transformer than the old connection, without any increase in hazard to the customer. As compared with unprotected transformers, he believes the connection gives much better protection to the customer because it prevents high voltage from entering into customers' circuits. Also the hazard of fire or personal injury is much greater from high voltage power current than it would be from any surge likely to pass through into customers' circuits.

A. S. Brookes (Newark, N. J.) discussed several details in the paper by Messrs. Harding and Sprague. He believes the analysis might have been made much more valuable by a more detailed consideration of the circuit distances involved, and if more data on the surge current and the circuit details were given. He felt that the interconnection of the primary arrester ground and the secondary neutral had more merits than the results given in the paper indicate.

J. K. Hodnette (Sharon, Pa.) discussed this subject from the standpoint of distribution transformer design. He described a self-contained, self-protecting transformer with gaps inserted between the high-voltage and low-voltage leads, and the ground, to enable the transformer to withstand many surges without injury to the insulation. This surge-proof transformer has withstood tests approximating service conditions as nearly as possible, with surges of various magnitudes up to 1,500,000 volts impressed upon the excited supply lines. In every case the transformer was protected and normal voltage was restored without causing so much as a flicker in lamps supplied from secondary leads of the transformer.

H. V. Putman (Sharon, Pa.) pointed out limitations of the proposed interconnection which he believed ought to be given careful consideration. He explained why he believed the straight interconnection not well adapted to installations having a low voltage neutral ground connection of high resistance, nor to installations without grounds on the service lines; nor yet to installations with grounded transformer tanks or to three phase installations.

M. G. Lloyd (Washington, D. C.) summed up results and conclusions of the several papers on lightning protection. He explained that the committee on protection against lightning of the National Fire Protection Association for some time has had under consideration the advisability of using lightning arresters on overhead secondary circuits where they enter buildings. This would seem necessary only in rural districts and where wires enter the building as separate open wires. Since it would be necessary to interrupt follow current at only 120 volts, an arrester of cheap construction would suffice.

J. J. Torok (East Pittsburgh, Pa.) discussed and carefully analyzed benefits to be obtained from the standpoint of personal hazard to the customer in the proposed interconnection of the lightning arrester ground lead and the neutral of the secondary. He explained that without the interconnection a power arc established across the transformer terminals would raise the secondary leads to primary potential. This condition would last as long as the arc was maintained, probably for several seconds. With the interconnection the action of the lightning arrester would come in at a voltage lower than that at which flashover of the transformer bushings would occur. Thus the arrester would prevent 60-cycle power follow or would limit it at most to a half-cycle duration. The power follow is more dangerous to life than the impulse voltages which, although of much higher values, are of short duration.

Edward Beck (East Pittsburgh, Pa.) described tests performed on a circuit set up in the laboratory to simulate an energized 2,300-volt circuit feeding a 110/220-volt house circuit with various household appliances attached. The transformer was protected with a 3,000-volt auto-valve arrester with the proposed interconnection employed. Surges were impressed on the primary of magnitudes sufficient to discharge 800, 1,600, and 3,000 amperes through the primary arresters, and cathode ray oscillograms were made of voltages occurring on the secondary system. The ground resistance was varied from zero to 57 ohms. The results revealed that the voltages to ground of the phase wires and the neutral wire were very nearly alike except for the first instant. Well over 1,000 surges were impressed and only three interruptions to the customers' service occurred. These consisted of blown fuses only. From the results obtained it was concluded that the interconnection did not impair conditions in the secondary system.

K. B. McEachron (Pittsfield, Mass.) discussed the proposed interconnection and described a modified form of conventional lightning arrester for installation within the space available inside the transformer tank. The arrester operation is in no way different than when applied externally, having the same factors of safety and the same reliability. This construction would have the advantages of reducing both installation costs and congestion on poles. Reasons, the result of experience, were given showing why gaps were unsuitable.

## General Circuit Theory

R. D. Evans (East Pittsburgh, Pa.) briefly reviewed some of the developments which have taken place in general circuit theory during the past 20 years. He told of any early problem in power system networks which was in connection with the supply systems for a-c. railways. This he explained was followed by a very important step in network theory; namely, the introduction of the method of symmetrical components by Doctor Fortescue, to make possible the solution of unbalanced power system networks. He further explained that recently the stability problem has made it necessary to develop new forms of circuit constants in order to facilitate the solution of general networks, taking into account not only distributed constants but their combination with lump constants. In conclusion, he pointed out that the most striking development within the last few years was the introduction of the a-c. calculating board. This has made possible the solution of many problems in a more complete manner and in less time than heretofore required.

### EQUIVALENT CIRCUITS

J. W. Butler (Schenectady, N. Y.) illustrated with examples the usefulness of the

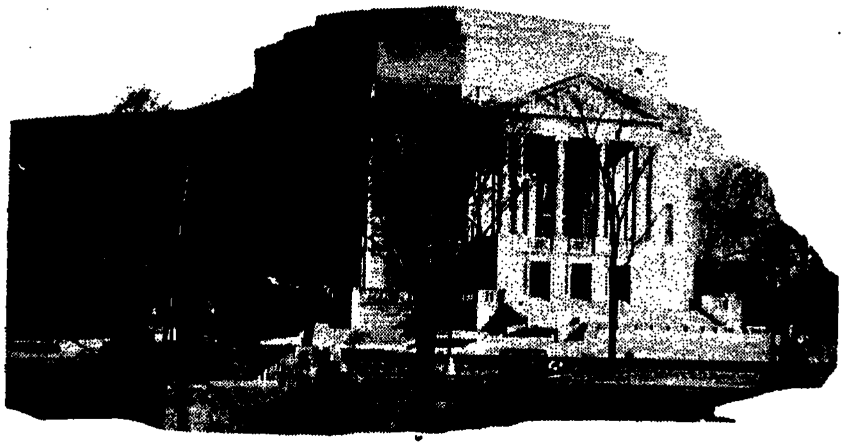
# Cleveland Cordially Invites You

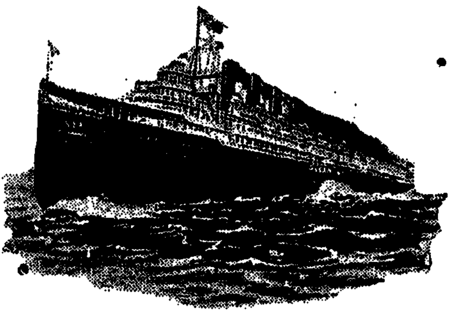
## To the Annual Summer Convention, June 20-24, 1932

The committees are working hard to assure you a profitable and entertaining visit. No registration fee.

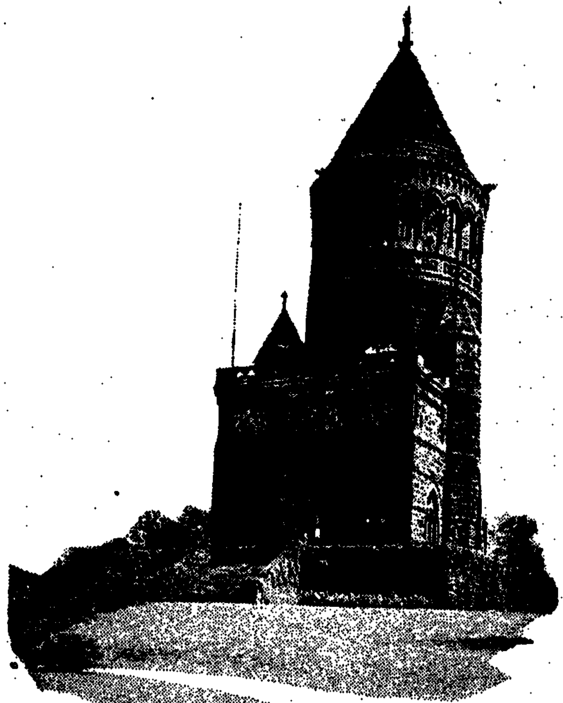
Cleveland Museum of Art, inspection of which is included in the ladies' entertainment program for Monday, June 20, 1932



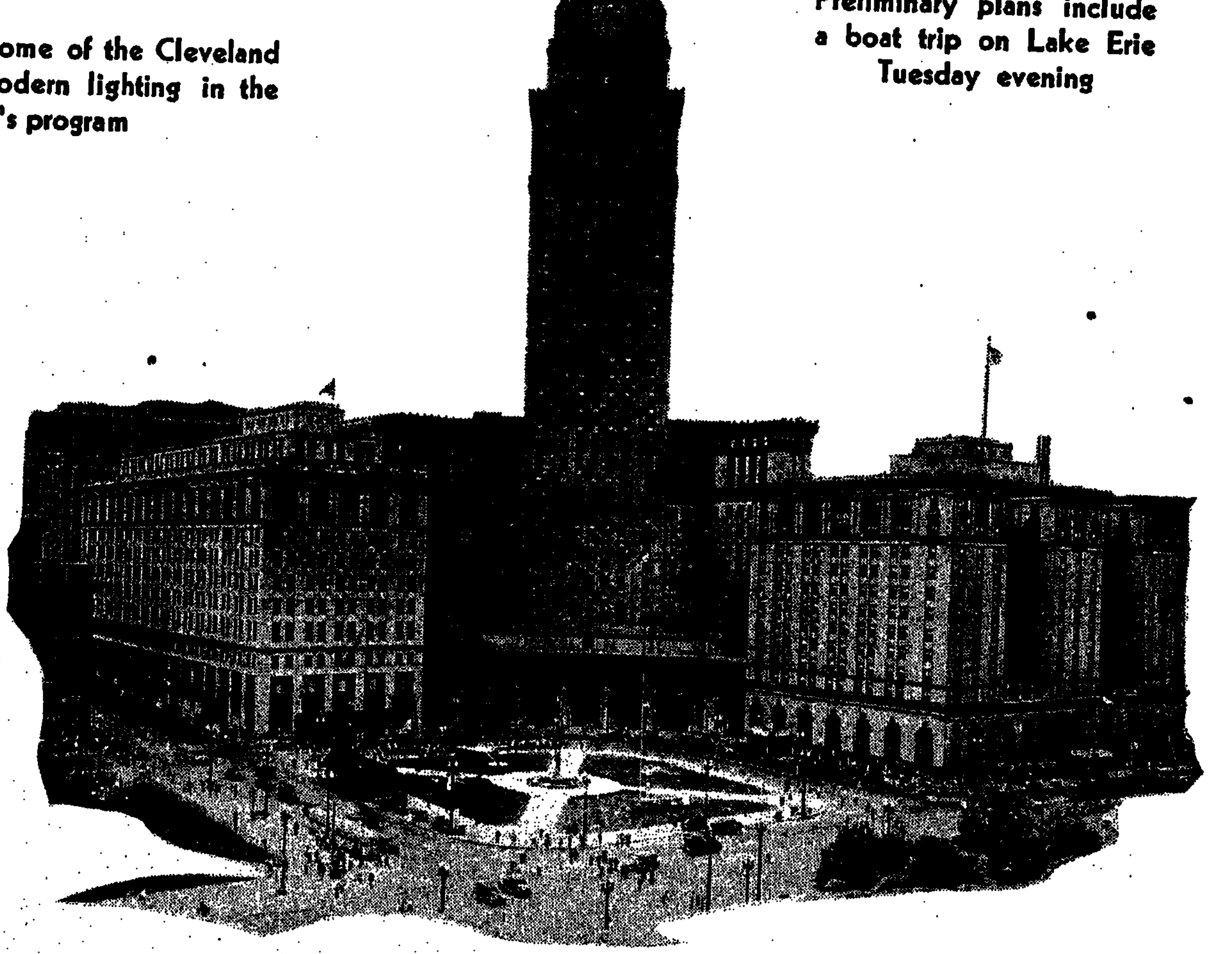
Inspection of Severance Hall, the new home of the Cleveland Symphony Orchestra, with the most modern lighting in the country, is included in Friday's program



Preliminary plans include a boat trip on Lake Erie Tuesday evening

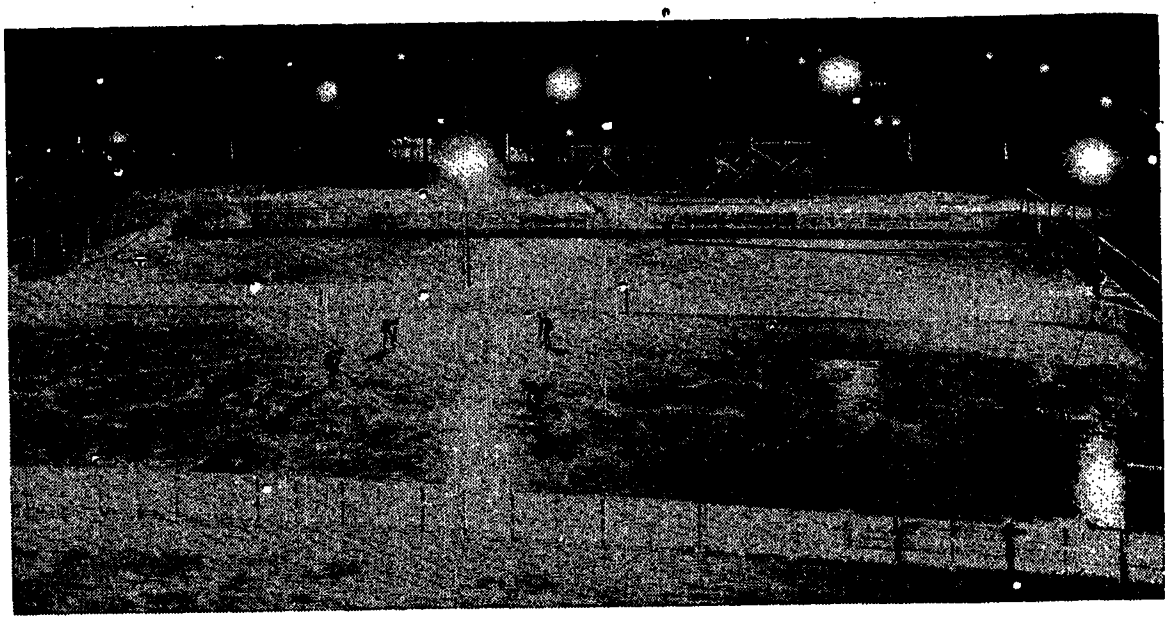


Garfield's Tomb, one of the many points of interest in Cleveland



The Cleveland Union Terminal group on Public Square, including Cleveland Hotel (at the extreme right) which is to be the convention headquarters

## Floodlighting for Hockey Rinks at Lake Placid



THE TWO hockey rinks and the adjacent ice skating speed tracks for the Olympic stadium at Lake Placid, N. Y., are floodlighted by the well diffused rays of 29 General Electric Company floodlights. Several of the hockey matches and races of the Olympic games, February 4–13, 1932, thus were successfully conducted at night. A total of 43 kw. is required to illuminate the 245 x 628 ft. of ice surface.

---

(*Winter discussion continued from p. 274*)

method which Mr. Starr had developed in part III of his paper, for setting up several simplified equivalent circuits. One example illustrated the simplicity of setting up an equivalent single line circuit to represent a four winding transformer.

Edith Clarke (Schenectady, N. Y.) explained that the paper on this subject presented the general circuit equations for networks in systematic and concise form, with methods for measuring and calculating the characteristic coefficients. She felt that Mr. Starr had made a valuable contribution to their solution. She believed also that one of the simplifications which will be found of advantage, where an a-c. calculating table is not available or when greater accuracy is required than can be secured by its use, is that of placing the self-impedance at the terminals and not in the mesh of the equivalent circuits.

R. G. Lorraine (Schenectady, N. Y.) discussed this subject and believes the paper, with its presentation of the general principles upon which the development of specific equivalent circuits depends, to be a welcome addition to the literature on equivalent circuits. One of the points which he emphasized was that even though the author's equivalent circuits contain pure reactance branches means are available to represent them adequately on the a-c. calculating table.

W. A. Lewis (East Pittsburgh, Pa.) found several of the equivalent circuits presented by the author to be both new and interesting. He believes a slight error in statement appeared on page 5 and again in the footnote on page 9, where it was stated that the mutual impedance between lines is purely reactive. It was explained that the mutual impedance is due not only to inductive coupling but also to the common use by all circuits of the earth and ground wires, if present. This resistance often may be as large in proportion to the mutual impedance as the combined resistances of earth circuit and conductor is to the zero phase sequence self-impedance. Therefore it seldom can be neglected unless the accuracy required permits neglecting all resistances.

George W. Hampe (Chicago, Ill.) in his discussion of this subject referred to previous work and the principles stated in 1911 by Mr. G. A. Campbell. He explained that the complete or lattice mesh, of which Fig. 1(d) and Fig. 3(b) of the paper are examples, could be handled more readily if admittances instead of impedances were used to express its links. A simple process for finding the branches of the complete mesh equivalent to the general concealed network was given by Mr. Campbell. The discusser gave an example of its derivation without the use of determinants.

### TRANSIENT OSCILLATIONS OF MUTUALLY COUPLED CIRCUITS

H. L. Rorden (Pittsfield, Mass.) discussed this subject and illustrated several points of interest with specific calculations based on Mr. Bewley's derivations. A table of calculated transients was given listing the essential terms for three space harmonics as calculated for the given constants, and conclusions drawn from these calculations were enumerated. An analogy also was given by comparing the general distributed circuit with the lumped constant circuit which exhibited similar characteristics.

## Drives for Power Station Auxiliaries

A. H. Kehoe (New York, N. Y.) told of experiences in the New York Edison system with both steam and electric drives for power station auxiliaries; continuity of station output has been obtained with either steam or electric auxiliary drive. This has been accomplished by supplying steam from headers which are provided with sectionalizing valves and fed from two or more sources, and each essential auxiliary motor circuit has its supply available from several sources. This system has found some saving in installed first cost of auxiliaries with electric drive instead of steam, especially where the simpler types of motors are adaptable.

I. E. Moultrop (Boston, Mass.) believed the papers presented on this problem were valuable and timely in bringing to the attention of the industry the need for more suitable and more economical drives. He predicted that auxiliary power requirements of the stations built in the future probably will be considerably in excess of those past or present. For high pressure boiler feed pumps he favored the use of turbine drive because it permits the best pump design, and the usual horsepower requirements permit a highly economical design. He called attention to the lack of satisfactory variable-speed a-c. motors, and many other interesting points were brought out in his discussion of this subject.

Francis Hodgkinson (Lester, Pa.) emphasized the importance of reliability of the drives for the essential power station auxiliaries. He discussed the trend in modern power plant design and in particular, stage bleeding for preheating, which no longer makes the exhaust heat from steam auxiliaries essential. His considerations in addition to the statements in the papers led generally to a preference for the electric drive for all essential auxiliaries except boiler feed pumps and fans.

H. M. Cushing (Buffalo, N. Y.) believed the trend of the development was clearly depicted in the three papers by Messrs. Hollister, Dryer, and Smith. However, he believed Mr. Dryer in handling the subject of steam driven auxiliaries had made a very favorable case for the electric drive. He was in agreement with all conclusions in this paper except Nos. 1, 5, and 8. It was explained that the Huntley Station started with a preponderance of steam driven auxiliaries. However, its engineers and operating men are now so convinced of the superiority of electric drive that in the new 60-cycle steam plant, known as Huntley Station No. 2, it was used exclusively for driving the auxiliaries. He explained further that the general use of electric drive had been delayed by a number of causes and pointed out many important features of the electrical installation for electric drives.

F. C. Hanker (East Pittsburgh, Pa.) reviewed the requirement for electric auxiliary drives and carefully analyzed the characteristics of the available types of apparatus. He felt that a great deal of the criticism of electric drive was due undoubtedly to the effort to apply motors and control developed for industrial uses to the more rigorous duties imposed by central station conditions. It was believed that the trend toward the unit system of operation should permit simplification of both the power supply and the auxiliary drive. Complications should be avoided in the sources of supply; this would simplify the control for the auxiliaries as well as minimize the duplication of auxiliaries, as is frequently done in practise.

Robert Baker (New York, N. Y.) discussed the financial side of this question. He believed that comparisons between steam and electric drives for auxiliaries should be made on the basis of between 30 and 40 per cent capacity factor instead of maximum load conditions, as described in the paper on electric drives. A comparison on this basis would represent more nearly the actual operating conditions and would probably show a reduced saving. He pointed out that no figures were given as to the cost of the steam driven equipment required for a station using steam driven auxiliaries and that comparisons could be made up only on the basis of fuel cost. It was explained that comparisons of this nature gave only half the picture as an analysis of the over-all operating costs of the average plant shows that the cost of fixed charges is approximately equal to the fuel cost.

Philip Sporn (New York, N. Y.) believes the aim in auxiliary layouts for future power plants should be toward further simplification of the power supply and control equipment. He believes the merits of systems were now fairly well recognized so that further standardization and simplification could take place. The need for a simple, sturdy, variable speed a-c. drive, improved insulation, and consideration of the use of higher voltage motors, were some other interesting points brought out in this discussion.

S. M. Dean (Detroit, Mich.) believes that the papers give a good summary of the two situations so far as the auxiliaries themselves were concerned. However, he would like to have seen somewhat more complete cost data. It was also pointed out that the possibilities of d-c. drives should not be overlooked. When account is taken of the extent to which the station rating is reduced (some 5 per cent) the smoothness and ease of operation, the absence of serious short-circuit problems, etc., it does not compare unfavorably with other methods.

F. M. Stoddard (Cincinnati, Ohio) briefly described auxiliary installations at the Columbia power station. Power for the essential auxiliaries is supplied from shaft generators connected to each main turbine unit. The non-essential auxiliaries are supplied from transformers connected to the main bus, and in six years of operation there has been no trouble with the auxiliary system from loss of auxiliary power or fluctuation of bus voltage caused by external faults.

F. H. Hollister (Chicago, Ill.) in his discussion on this subject showed data on several desirable features of the Rossman drive which has been in successful operation for the past year, driving fans at the Powerton station.

## Symposium on Stability

### STANDARD DECREMENT CURVES

R. G. Lorraine (Schenectady, N. Y.) discussed this subject and analyzed the development and use of several of the curves presented in the paper. An example illustrating their use was given and further inspection of them showed that more confidence could be placed in the use of these curves than one would suppose from an inspection of the assumptions made in their derivation.

### DECREMENT CURVES FOR SPECIFIC SYSTEMS

H. B. Dwight (Cambridge, Mass.) discussed this paper with particular reference to a method for calculating sustained short-circuit currents using Potier reactance. He explained that for this calculation the value of armature ampere-turns at rated current is also required, and this may be obtained from the Potier triangle. A certain amount of zero power-factor armature current may be assumed and the excitation calculated using Potier reactance and armature ampere-turns. It was further explained that since the excitation usually is known, the calculation must be repeated with adjusted values of armature current until the resulting excitation has the correct value. This process seems necessary, and does not make the calculation unduly long.

### PROPOSED DEFINITIONS OF POWER SYSTEM TERMS

V. J. Cissna (New York, N. Y.) explained the preference for the convention of leading reactive power as positive, particularly on account of the power-circle diagram. This he illustrated with a figure. It was believed that in considering leading reactive power as negative the convention of the power-circle diagram had been troublesome to many engineers in that the conventional rotation of voltage vectors had been violated.

C. L. Dawes (Cambridge, Mass.) commented on the committee's definition of lagging reactive power in terms of the current delivered by an over-excited synchronous generator. He believes this to be an indirect and unnecessary method of defining reactive power and also that it is confusing to those who do not have immediately in mind the excitation characteristics of synchronous apparatus. Such reactive volt amperes he believes could have been much more explicity defined as the reactive volt amperes taken by an inductive reactance, and this would be easily understood by everyone familiar with alternating currents.

C. F. Wagner (East Pittsburgh, Pa.) also discussed this question as to whether or not inductive reactive power should be plotted as a positive or as a negative quantity in power circle diagrams. He gave a list of references to publications in which inductive reactive power is considered positive and also a list in which it is considered negative. These references dated over a period from 1910 to 1929, twenty-three authors considering inductive reactive power as positive while sixteen considered it as negative. In addition, authors such as Doctor Kennelly, Professor Jackson, and Doctor Fortescue, also preferred the use of the positive value. Therefore, the discusser believes that the inductive reactive power as a positive quantity should be adopted as the convention.

Edith Clarke (Schenectady, N. Y.) explained that she was in agreement with the proposal to consider leading reactive power positive and lagging reactive power negative. It was explained why voltage is chosen as the reference vector in dealing with network systems; the currents in the branches of the network then give a good indication of both active and reactive power flow. This correspondence of power and current was believed to be of sufficient importance to justify the proposed convention for active and reactive power.

A. E. Kennelly (Cambridge, Mass.) told of the work done by the International Electrotechnical Commission and analyzed considerations of the question as to whether reactive power should be represented by $P + jQ$ or $P - jQ$ vector voltamperes. He believes the subject committee here should transmit a recommendation to the A.I.E.E. standards committee as to the choice of vector direction so that the standards committee may be able to take early appropriate action with a view to renewing international proposals. If the reasons given for the final choice are cogent, he believes they would be likely to meet with indorsement from our engineering fraternities in other parts of the world.

L. A. Kilgore (East Pittsburgh, Pa.) discussed section 4 of this report covering the definition of synchronous machine constants with particular reference to the effects of saturation. He believes the report does not offer any simple method of dealing with the effects of saturation but leaves its degree indefinite. This he thinks might be confusing when using the constants in practical calculations for it appears we must have not only a large number of constants but different values for various conditions. It also will be necessary to state the degree of saturation every time a value of the constant is specified. He recommends from the conclusions of previous work, a definite and relatively simple means of dealing with saturation.

S. L. Henderson (East Pittsburgh, Pa.) believes the report to be a valuable piece of work. He suggests that a statement would be helpful in covering the particular machine constants to be used most often in the ordinary study of system performance. For example, values of transient, substransient synchronous, and negative and zero sequence reactances for the direct axis, together with the short-circuit ratio and the short-circuit time constant, are sufficient for the usual practical case.

### GENERALIZED STABILITY SOLUTION FOR METROPOLITAN TYPE SYSTEMS

R. D. Evans (East Pittsburgh, Pa.) called attention to the value of the generalized methods given in this paper. He explained that the general stability curves given in this paper may be used in a manner similar to that of the paper "Standard Decrement Curves" presented earlier in the session. It was predicted that the use of these curves together with previous curves developed for long distance straightaway transmission will lead to the development of similar methods for the remaining types of systems so that eventually shortcut methods will be available for all types of systems.

Another discussion by S. B. Crary (Schenectady, N. Y.) brought out that any generalization or simplification of a problem which comprises as many factors as a transient stability study, must require numerous assumptions and these limit the field of application. Therefore he believed that care must be used in applying the curves of Figs. 1 and 2 to systems that do not conform to the assumptions set forth.

S. H. Wright (Buffalo, N. Y.) explained that when applying the curves presented in the paper cases may frequently arise where conditions of the system being studied are met by the conditions assumed in preparing the curves except in one respect, making it desirable to consider the inertia constant as an additional "index factor." This was illustrated by an example.

### ELECTRICAL STABILITY OF CONOWINGO HYDROELECTRIC STATION

R. M. Spurck (Philadelphia, Pa.) discussed the last paper to be presented in this session. He believed the authors presented an excellent and complete paper on the analysis and solution of stability problems which occurred in connection with the operation of this station, both before and after the application of high-speed clearing equipment to the system. It was brought out that the correction of stability problems by high-speed circuit clearing also brings with it many other benefits, a few of which are reduced area of disturbance on the system during faults, reduction in voltage dips, and apparatus that requires less maintenance.

## Research

### RADIO INTERFERENCE FROM INSULATOR CORONA

J. W. Upp, Jr. (Baltimore, Md.), discussed this subject and he believes that over a period of years, insulator manufacturers interested in radio interference investigations have found modern insulators to be minor offenders. Insulators, he thinks, are further along the path of development of radio interference relief than most of the other factors involved in the manufacture, transmission, and consumption of electrical energy.

W. A. Hillebrand (Barberton, Ohio) inquired if the author of this paper considered his set-up suitable for a standardized test set, if he had any changes to recommend, and if, in his opinion, it had been described with sufficient accuracy in his papers to permit of its being accurately reproduced.

S. K. Waldorf (Baltimore, Md.) discussed several means for corona detection, one of which consisted of employing an audible corona detector having one or two stages of audio frequency amplification designed to accentuate frequencies greater than approximately 500 or 1,000 cycles per sec., and having a radio headset or loud speaker in the output. With this type of detector, even the presence of a small amount of corona is accompanied by a loud buzzing sound in the telephone or loud speaker. He also explained that it may be desirable in some cases to connect the input resistance of the corona detector in the grounding circuit of the insulator suspension or pin.

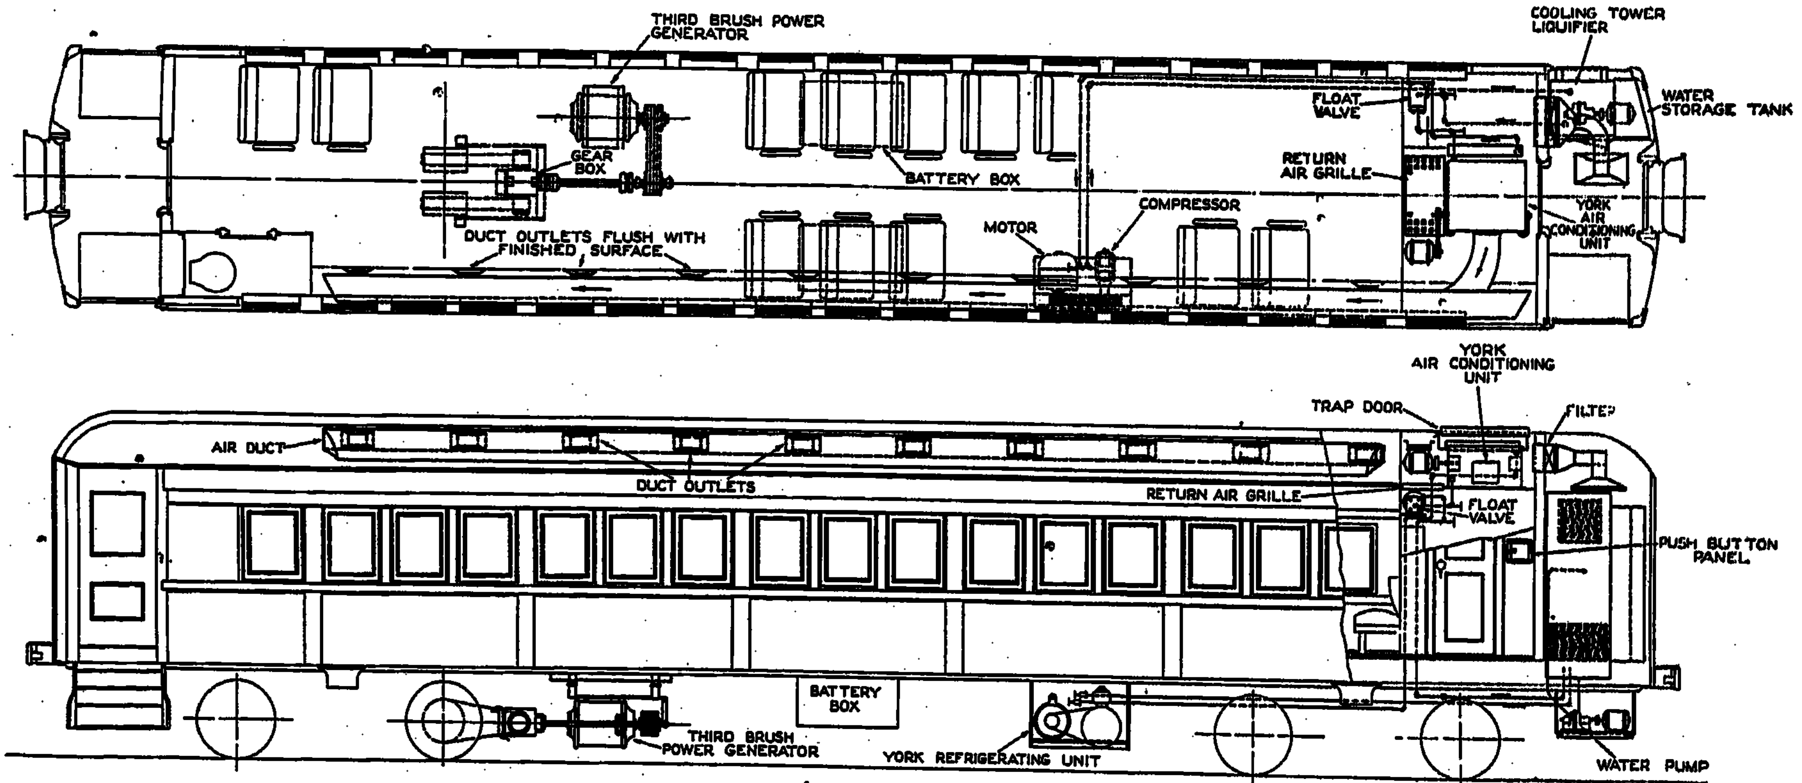
J. B. Whitehead (Baltimore, Md.) discussed the experimental method used in the paper with reference to balancing out the charging current of the high voltage circuit, the adjustment being made before corona forms. He explained that it is well known, however, that the presence of corona, owing to space charge formation, introduces important changes in the value of the geometric capacitance. It was believed that this fact might explain some of the irregularities in the records and have a bearing on the differences observed as between the negative and positive half-cycles.

Another discussion of this subject by A. C. Seletzky (Cleveland, Ohio) suggested that in view of the varying results obtained, a quantitative method of detecting the initial presence of corona should be used, as it would give more consistent results. Such a method he believes would be able to detect corona in parts of the insulator which are difficult, if not impossible, to observe accurately by visual means, even under the most favorable conditions and a darkened room.

### PREDETERMINATION OF A-C. BEHAVIOR OF DIELECTRICS

H. H. Race (Schenectady, N. Y.) discussed this subject and it is his belief that the paper presents some very interesting data but it does not suggest a physical explanation of the results. He was particularly interested in Fig. 5, because the variations of capacitance and loss with frequency are similar to corresponding curves calculated using a very definite physical picture; namely, Debye's theory of polar molecules. An analysis and comparison of the two theories were made which led to several more general and interesting conclusions.

# Baltimore & Ohio to Equip More Cars for Air-Conditioning



AN INITIAL ORDER for new and improved equipment for 78 passenger cars has been placed [with the York Ice Machinery Corporation of York, Pa.] by the Baltimore & Ohio Railroad, pioneer in train air-conditioning. The new equipment, like that employed in the initial installation, is self-contained in each car to permit flexibility of operation. Power for driving the equipment is obtained from a newly developed three-brush generator, axle driven through a special gear and pulley arrangement, and a new high-capacity storage battery. Refrigeration is carried out in a closed cycle. The refrigerating unit consists of a compressor, specially designed for use with Freon gas (dichloro-difluoro-methane) and driven by an electric motor with both high and low pressure cut-outs and gages. The new gas employed is a colorless, odorless, non-corrosive, non-combustible, and non-inflammable refrigerant which may be used in equipment passing through tunnels without any serious hazard to health. The new equipment is said to have 50 per cent increased capacity, but to require less space than that used by the B & O in their original installation. Either an air-cooled or cooling-tower liquifier may be used, depending upon operating conditions; identical results are expected with either type. The accompanying illustration shows a typical passenger car installation, in which may be noted the arrangement of equipment and air passages. The entire system is controlled from a push-button station near one end of the car.

Another discussion by F. M. Clark (Pittsfield, Mass.) told of determining the relative a-c. characteristics of 5-kva. oil-filled capacitors by means of the so-called d-c. leakage. This appears to be of greater value than insulation resistance measurements, but the work was not carried sufficiently far to predict successfully the power factor from the leakage results obtained; however, it was believed that this could be done.

W. A. Del Mar (Yonkers, N. Y.) also discussed this subject and brought out the fact that the practical control of power factor of impregnated paper now lies with the paper tests, where formerly it was essentially a matter of oil resistivity. This change occurred when manufacturers changed their paper from manila to wood pulp, and oil from petrolatum to cylinder oil. He believes that the practical problem has long since been solved, but it would be interesting to have the authors explain these facts in the light of their admirably developed theories.

### BREAKDOWN OF GLASS WITH ALTERNATING POTENTIALS

J. B. Whitehead (Baltimore, Md.) discussed this paper and found it difficult to accept the suggestion of Moon and Norcross, and now of these authors, that the intermediate stage of breakdown should follow a definite law.

W. A. Del Mar (Yonkers, N. Y.) discussed the authors' contention that three distinct regions of dielectric failure, instead of two, exist with alternating currents. He believes that the authors in justice to their thesis should give Fig. 4 with the experimental points plotted.

W. A. Hillebrand (Barberton, Ohio) discussed the nature of glass, the material used in these tests. He explained that glass is a physical solution, an electrolyte, the constituents of which are ionized, and that it has the high negative temperature coefficient of resistance characteristic of electrolytes. Furthermore, some of its physical properties are indefinite. Therefore, the discusser did not believe it was impossible that there should be a region of dielectric breakdown intermediately between the disruptive and thermal regions partaking of the nature of both and representing a transitional stage.

Another discusser, F. M. Clark (Pittsfield, Mass.) also drew attention to the nature of the material used. He believes that the conclusions drawn by the authors, even if accepted, should be limited carefully to glass of the type under discussion which also should be more clearly described than it was in the paper.

### MAGNET STEELS

This subject was discussed by W. A. Codd (Rochester, N. Y.) who believes that the paper checks experimentally Evershed's criterion of magnetic quality for magnet steels and apparently offered a considerably simplified design method in the nomogram presented. The discusser also inquired in detail about many points in this paper.

---

**Editor's Note:** The remainder of these summaries of winter convention discussions is scheduled for inclusion in the May 1932 issue of ELECTRICAL ENGINEERING.

## Executive Committee of Institute Meets

A meeting of the executive committee of the American Institute of Electrical Engineers was held at Institute headquarters, New York, N. Y., on Wednesday, March 9, 1932, in place of the regular March meeting of the board of directors.

Present were: C. E. Skinner, *chairman*, and H. P. Charlesworth, J. Allen Johnson, W. S. Lee, F. W. Peek, Jr., W. I. Slichter, and C. E. Stephens, of the committee, and Assistant National Secretary H. H. Henline.

Resolutions were adopted in memory of the late National Secretary F. L. Hutchinson and Past-President Harold B. Smith, as published elsewhere in this issue.

Resolutions were adopted, authorizing and empowering H. H. Henline, assistant national secretary, to perform all of the duties of the office of national secretary until further order of the executive committee or the board of directors.

Approval was given to actions taken by the board of examiners at its meeting of March 2, 1932; and upon the recommendation of the board of examiners the following actions were taken upon pending applications: one applicant was elected to the grade of Fellow and two were transferred to the grade of Fellow; two applicants elected and 21 transferred to the grade of Member; 218 Associates elected; 99 Students enrolled.

The approval by the finance committee for payment of monthly bills amounting to $28,519.97 for January and $25,729.56 for February was ratified.

The assistant national secretary reported that upon being advised of the action of the board of directors in January, calling for a reduction in the expenses of the meetings for the remainder of the year 1932, the executive committee of the Southern District (No. 4) had voted to cancel the District meeting scheduled to be held in Memphis, Tenn., in November, 1932, with the idea that a meeting will be held the latter part of 1934 instead.

Appointment by the president of the following committee of tellers to canvass and report upon the ballots cast in the 1932 election of Institute officers, was confirmed: J. T. Wells, *chairman*, L. B. Bogan, H. B. Ely, C. S. Purnell, G. J. Read, R. H. Twiss, and Ernst Volckmann.

The resignation of J. C. Parker as a representative of the Institute on the standards council of the American Standards Association was presented, and the president was authorized to appoint a representative for the unexpired term of Mr. Parker, ending December 31, 1932.

Col. W. B. Jackson was appointed a representative of the Institute on the Commission of Washington Award, for the 2-year term beginning June 1, 1932, to succeed Prof. C. F. Scott, whose term expires at that time. Appreciation of the services rendered by Professor Scott in this capacity over a long period of years, was expressed.

The president was empowered to nominate for appointment by the president of the National Academy of Sciences, a representative of the Institute on the division of engineering and industrial research of the National Research Council, for the 3-year term beginning July 1, 1932, to succeed F. W. Peek, Jr., whose term expires at that time and who is ineligible for immediate reappointment.

Upon recommendation of the committee on education, it was voted to endorse the activity of the Society for the Promotion of Engineering Education in its summer schools for engineering teachers.

An invitation from the National Academy of Sciences to be represented by a delegate at the celebration of the one hundredth anniversary of the electrical discoveries of Joseph Henry, on the evening of April 25, 1932, in Washington, D. C., was accepted, and the president was authorized to appoint a delegate.

It was also voted to accept the invitation to send a representative to the celebration, on April 11, 1932, of the opening of the new patent office in Washington.

Other matters were discussed, reference to which may be found in this and future issues of ELECTRICAL ENGINEERING.

**Doctor Langmuir Receives Science Award.**—The annual award of $10,000 offered by *Popular Science Monthly*, this year went to Dr. Irving Langmuir, physicist, chemist, and associate director of the research laboratories of the General Electric Company. The following institute members were among the committee of eminent engineers and scientists which chose Dr. Langmuir: Dr. F. B. Jewett (A'03, F'12), vice-president of the American Telephone and Telegraph Company, *chairman;* Dr. C. F. Kettering (A'04, F'14) president and general director of the General Motors research laboratories; Dr. S. M. Kintner (A'02, M'03) vice-president of the Westinghouse Electric and Manufacturing Company; Dr. R. A. Millikan (M'22) chairman of the executive council, California Institute of Technology; Philander Norton (A'11) assistant to the president, Bell Telephone Laboratories; and Dr. Willis R. Whitney (A'01) vice-president and director of research of the General Electric Company.

**A.A.A.S. and Associated Societies to Meet at Syracuse.**—Following the custom established last year of holding annually a summer meeting of truly national character, the American Association for the Advancement of Science, together with associated societies, will hold their second annual summer meeting in Syracuse, N. Y., June 20–25, 1932. Syracuse University will act as host for the meeting. Dean H. P. Baker of the College of Forestry has been appointed chairman of the steering committee and has organized the various committees which are to function in making the stay of the 2,000 scientists, who it is expected will attend the meetings, a pleasant one. The facilities at Syracuse University have been found suitable as a meeting place for such a large group. In addition to the hotels, University accommodations will be available for housing the visitors during the week of the convention. Visiting scientists will be able to make excursions to any points of interest in the vicinity, and guides will be furnished for the various trips.

# Post-College Education Popular With Chicago Engineers

FOR NEARLY three years the educational committee of the Chicago Section of the Institute has been actively promoting the post-college education of engineers in that district. Prof. Edward Bennett, chairman of the Institute's committee on education, set forth the case for post-college education for engineers in his article in the JOURNAL of the Institute for April 1929, p. 310, and R. F. Schuchardt, then president of the Institute, gave further encouragement to the idea in his editorial on p. 259 of the same issue. The annual report of the committee on education under Professor Bennett's chairmanship was given in the JOURNAL for September 1929, p. 677, and amplifies the importance of stimulating interest in the systematic continuation of engineering education after college.

The Chicago Section actively took up the work of post-college education among engineers and has obtained surprisingly successful results. A progress report on activities of the education committee of this Section has been prepared by Burke Smith, chairman, and should be of interest to other Sections. The paragraphs following are taken from Mr. Smith's report:

An education committee for the Chicago Section was appointed in the summer of 1929 and has continued to function since that date. The committee at that time had no data to guide it, since no educational work of the nature here considered was being done by any engineering organization in Chicago. A questionnaire was sent to the membership requesting a reply from those members who would be interested in continuing their education by attending evening classes or lectures along certain specified technical lines. Out of some 1,200 members, replies were received from approximately 100, a rather meager response which in the light of the success of all courses offered indicates that questionnaires are of value only in so far as they are indicative of choice between different courses.

As a result of a preliminary study of the situation by the committee, the following conclusions were reached:

1. It appeared to be worth while to arrange for educational courses to be offered in the evening, a fee to be charged covering the cost of instruction.

2. While it is recognized that cultural subjects are of great value and interest to practising engineers, such subjects are offered by various educational institutions in Chicago or by correspondence courses and there appeared to be no need, therefore, for the Institute to arrange for courses of this nature.

3. It was felt that due to the limitations of the present 4-year engineering curriculum, practising engineers would be interested in technical subjects of a somewhat advanced nature which would supplement their undergraduate work.

4. In addition to the need for formal classroom work in advanced subjects, it was assumed that there is also a desire for lectures covering recent developments in physical science which would enable practising engineers to keep in touch with contemporary scientific progress.

5. It was proposed that any courses offered should be administered by an educational institution rather than by the Institute, thus relieving the Institute of the responsibility for arranging for instructors or lecturers, determining the form in which the subject matter should be presented, collecting fees, etc.

After a program of courses had been planned, it was decided to invite other engineering organizations in Chicago, such as the Western Society of Engineers and the Chicago Section of the Institute of Radio Engineers to join, so that a larger number of engineers might be interested and the enrolment in any courses offered might be increased correspondingly.

In accordance with the above policy, the following courses were offered, beginning in January 1930:

1. Engineering Economics. Classroom instruction, one session each week for ten weeks. This course was given by Armour Institute of Technology under the direction of Prof. E. H. Freeman; fee for the course, $10.

2. A lecture series on recent developments in electron physics and electrochemistry consisting of ten evening lectures, one per week, by members of the staff of the University of Chicago; fee for the series, $5. The following subjects were covered: the nature of the electron, the nature of heat, the nature of light, cosmical matter, molecular spectra and molecular structure, the arrangement in solids, modern theories of strong electrolytes, the electron in organic chemistry, the Werner coordination theory, and atomic species, isotopes and radioactivity.

The registration in engineering economics proved to be so large, 126 persons, that it was necessary to divide the class into two sections. Early in the fall of 1930 arrangements were made with Armour Institute of Technology to repeat the course, and a second class was organized with a registration of 39.

The registration in the lecture series on recent developments in electron physics and electrochemistry was 290. In view of the evident interest in these lectures an additional series of three lectures on electronics and three lectures on the theory of conductors and dielectrics was offered beginning in October 1930 and covering the following subjects:

Classical electron theory and positive rays, modern conceptions of the electron, television and the electron, conduction in gases, conduction in liquids and solids, and conduction in dielectrics.

The registration for the first three lectures was 355 and for the last three, 208. The fee for each series of three lectures was $1.

The total number of registrations for the courses offered during the calendar year 1930 amounted to 1,018.

Activities during 1931 consisted of the following, all offered by the University of Chicago:

1. A classroom course in transient phenomena and advanced circuit theory offered in January in connection with the evening school which the University maintains in the downtown district of Chicago. The registration was 43, and the regular tuition fee of $12.50 for 12 weeks was charged. The University of Chicago does not have an engineering school, but arrangements were made to secure Prof. E. B. Paine of the University of Illinois as instructor.

2. A classroom course in modern circuit theory beginning in October and continuing for 24 weeks. The registration was 40, and the regular tuition fee of $25 charged.

3. A series of three lectures on acoustics given in October. Registration, 210. Fee for the series, $1.50.

All of the above courses were open to any who cared to register for them and were offered with the cooperation of the Chicago Section of the Institute of Radio Engineers and the Western Society of Engineers. From 28 to 38 per cent of those who attended were members of the Institute.

The question of fees was discussed with the educational institutions and the amount to be charged for each lecture series was determined on the basis of meeting expenses with the expected enrolment. It was understood that if expenses were not covered by the fees in the initial courses the Institute would share with the educational institutions in making up the deficit. For the classroom courses offered by the University of Chicago, it was understood that none would be given if a sufficient number of students was not enrolled at the first meeting to make it possible to meet expenses. Those who had not been enrolled previously in the University were charged a matriculation fee for these courses.

## CONCLUSIONS

Based on the record of a registration of over 1,000 in the courses which were offered during 1930, and a continuation of interest during 1931, there can be no doubt that under the conditions existing in Chicago there is a desire for post-college evening courses of the following general nature:

1. Classroom work covering advanced subjects such as are usually given in resident post-graduate courses in mathematics, physics, and engineering subjects.

2. A connected series of lectures on selected topics in the physical sciences, given by specialists and designed to enable graduates to keep up with contemporary advances in these fields.

The question arises as to whether the demand for educational courses of the type described will continue. It seems that this will depend upon how well the local education committee succeeds in interpreting and putting into effect the wishes and needs of the members. Evening instruction in engineering subjects of an undergraduate level is not a new idea. That evening instruction of an advanced nature can be offered successfully over a period of years is shown by the experience of the Chicago Section of the American Chemical Society, which since 1923 has provided for its members instruction in advanced courses in chemistry, with results which have been uniformly successful. A description of this project is given in an article by Arthur Guilladeau and W. V. Evans in the *Journal of Chemical Education* for November 1928. Another example is that of the Polytechnic Institute of Brooklyn which for a number of years has maintained evening classes in engineering subjects of graduate level.

It is believed that if a definite sequence of courses is laid out requiring two or three years for completion, there will be many engineers who will wish to enroll for the entire series. Such a sequence may be selected easily although obviously the particular courses which may be offered will depend upon the possibility of arranging for instructing personnel.

Following is a brief list of subjects which might form the nucleus of such a sequence. Many of these subjects are now offered as resident advanced courses in our larger engineering schools and universities. Some are more suitable for classroom work and others for a lecture series. The list of course could be greatly extended:

**Engineering economics, differential equations for engineers, vector analysis with engineering applications, electric wave theory, Heaviside's operational calculus with applications, transient phenomena and advanced circuit theory, advanced theory of electrical machinery, theory of vacuum tubes and their circuits, acoustics, modern theories of magnetism, conduction of electricity through gases, modern theories of the electron, theory of conductors and dielectrics, the photoelectric effect, and the quantum theory of radiation.**

Where facilities for experimental work and credit toward an advanced degree can be offered in connection with evening work a larger number of students will be attracted. Such facilities are available to evening students in only a few of the larger centers, however, and in most cases the instruction must of necessity be theoretical. In this connection it is possible that reading courses or a reading list service covering advanced subjects for the guidance of those engineers who do not live within easy reach of educational centers would be welcomed. At least one large university is now offering such a service to its alumni to enable them to follow a systematic course of reading in fields in which they are particularly interested. Results in Chicago to date indicate more interest in courses in pure science than in advanced engineering subjects.

It is well known that many industrial organizations offer technical training to their employees either in cooperation with the universities or as instruction courses under the direction of their own staffs. Such training is usually along special lines pertaining to the particular industry and does not supply the need for more fundamental courses or for work leading to an advanced degree. The educational activities of industrial organizations should supplement rather than conflict with any program which may be set up by the Institute Sections.

An educational program is a joint undertaking and in order to be successsful the responsibility for it must be shared by both the educational institutions and the engineers. There is ample evidence that the colleges and universities are alive to the situation and are willing to do their part. Now, therefore, is an opportune time for the Sections, through their education committees, to take the lead in making known their needs and developing plans to satisfy these needs in cooperation with the universities.

In conclusion, it may not be amiss to take stock of the results which may be expected to accrue over a period of years from a systematic educational program such as is here outlined:

**1. The cooperation of educational institutions and engineering societies will result in a closer affiliation of all the groups concerned.**

**2. The engineers individually and the industries in which they are employed will gain from the further training and broader outlook of those who participate.**

**3. An increased appreciation of the value of the Institute to members and non-members alike will result.**

In view of the evident desire on the part of practising engineers for a continuation of engineering education, and the future possibilities in this field, the statement from the report of the committee on education which was quoted at the beginning of this article does not seem to over-emphasize the importance of the movement and the need for adequate provision for a program of post-college education.

## M.I.T. Plans New Division of Studies

The distribution of its curriculum into five distinct branches, namely, school of science, school of engineering, school of architecture, division of humanities, and division of industrial cooperation, was announced March 10, 1932, by Dr. Karl T. Compton, president of Massachusetts Institute of Technology. The following appointments have been made accordingly: Dr. Vannevar Bush (A'15, F'24) a member of the faculty of electrical engineering since 1923, vice-president and dean of engineering; Dr. Samuel C. Prescott, dean of science; Prof. William Emerson, dean of architecture.

Doctor Compton is quoted as having stated that this new plan is a natural extension of an administrative plan started two years ago in the appointment of a chairman of the corporation and a president of the M.I.T. The new subdivision recognizes the five major aspects of the work, the three schools comprising those departments in which degrees are given, and the two divisions, essentially for "service" purposes, to give the students the benefit of a further cultural training and background deemed essential to a well-balanced training, and designed to make as effective as possible the assistance which the M.I.T. desires to render in various ways in solving the technical problems of business and industry.

What is counted an important feature of this new plan is definite recognition of the graduate school. With every evidence that this work is becoming relatively more and more important, it has seemed advisable to provide more adequately for its constructive administration through the establishment of a graduate school embracing

## The Engineer—a Parable

ONE DAY three men, a Lawyer, a Doctor, and an Engineer, appeared before St. Peter as he stood guarding the Pearly Gates.

The first man to step forward was the Lawyer. With confidence and assurance, he proceeded to deliver an eloquent address which left St. Peter dazed and bewildered. Before the venerable Saint could recover, the Lawyer quickly handed him a writ of mandamus, pushed him aside, and strode through the open Portals.

Next came the Doctor. With impressive, dignified bearing, he introduced himself: "I am Dr. Brown." St. Peter received him cordially. "I feel I know you, Dr. Brown. Many who preceded you said you sent them here. Welcome to our City!"

The Engineer, modest and diffident, had been standing in the background. He now stepped forward. "I am looking for a job," he said. St. Peter wearily shook his head. "I am sorry," he replied, "we have no work here for you. If you want a job, you can go to Hell." This response sounded familiar to the Engineer, and made him feel more at home. "Very well," he said, "I have had Hell all my life and I guess I can stand it better than the others." St. Peter was puzzled. "Look here, young man, what are you?" "I am an Engineer," was the reply. "Oh yes," said St. Peter, "Do you belong to the Locomotive Brotherhood?" "No, I am sorry," the Engineer responded apologetically, "I am a different kind of Engineer." "I do not understand," said St. Peter, "what on Earth do you do?" The Engineer recalled a definition and calmly replied: "I apply mathematical principles to the control of natural forces." This sounded meaningless to St. Peter, and his temper got the best of him. "Young man," he said, "you can go to Hell with your mathematical principles and try your hand on some of the natural forces there!" "That suits me," responded the Engineer, "I am always glad to go where there is a tough job to tackle." Whereupon he departed for the Nether Regions.

And it came to pass that strange reports began to reach St. Peter. The Celestial denizens, who had amused themselves in the past by looking down upon the less fortunate creatures in the Inferno, commenced asking for transfers to that other domain. The sounds of agony and suffering were stilled. Many new arrivals, after seeing both places, selected the Nether Region for their permanent abode. Puzzled, St. Peter sent messengers to visit Hell and to report back to him. They returned, all excited, and reported to St. Peter:

"That Engineer you sent down there," said the messengers, "has completely transformed the place so that you would not know it now. He has harnessed the Fiery Furnaces for light and power. He has cooled the entire place with artificial refrigeration. He has drained the Lakes of Brimstone and has filled the air with cool perfumed breezes. He has flung bridges across the Bottomless Abyss and has bored tunnels through the Obsidian Cliffs. He has created paved streets, gardens, parks and playgrounds, lakes, rivers, and beautiful waterfalls. That Engineer you sent down there has gone through Hell and has made of it a realm of happiness, peace, and industry!"

---

**By D. B. Steinman, President of the New York State Society of Professional Engineers, and Past-President of the American Association of Engineers. Reprinted from "The American Engineer" for January 1932.**

engineering, science, and architecture. Notwithstanding this new subdivision, however, the faculty as a whole will continue to be the final authority in matters of educational procedure. The new organization provides for an administrative council, an informal organization which will hold weekly meetings in order to keep fully informed of the progress of various departments. This council will consist of President Compton, Vice-President Bush, members of the executive committee, Dean Prescott, Dean Emerson, the president of the alumni association, the chairman of the faculty, the director of the division of industrial cooperation, the deans of graduate students and students, and the bursar.

## To Institute Members Planning Trips Abroad

Members of the Institute who contemplate visiting foreign countries are reminded that since 1912 the Institute has had reciprocal arrangements with a number of foreign engineering societies for the exchange of visiting member privileges, which entitle members of the Institute while abroad to membership privileges in these societies for a period of three months and members of foreign societies visiting the United States to the privileges of Institute membership for a like period of time, upon presentation of proper credentials. A form of certificate which serves as credentials from the Institute to the foreign societies for the use of Institute members desiring to avail themselves of these exchange privileges may be obtained upon application to Institute headquarters, New York. The members should specify which country or countries they expect to visit, so that the proper number of certificates may be provided, one certificate being addressed to only one society.

The societies with which these reciprocal arrangements have been established and are still in effect are: Institution of Electrical Engineers (Great Britain), Société Française des Electriciens (France), Association Suisse des Electriciens (Switzerland), Associazione Elettrotecnica Italiana (Italy), Koninklijk Instituut van Ingenieurs (Holland), Verband Deutscher Elektrotechniker E. V. (Germany), Norsk Elektroteknisk Forening (Norway), Svenska Teknologforeningen (Sweden), Stowarzyszenie Elektrykow Polskich (Poland), Elektrotechnicky Svaz Ceskoslovensky (Czechoslovakia,) The Institution of Engineers, Australia (Australia), Denki Gakkwai (Japan), and South African Institute of Electrical Engineers (South Africa).

**Touring Arrangements for I.E.C. Congress.**—For those going to the International Electrical Congress to be held this summer in Paris, France, provisions have been made with Thomas Cook & Son to provide transportation arrangements for those desiring to avail themselves of this service. According to the best information available, the congress will open Monday, July 4, 1932, and close July 12. Accordingly, Thomas Cook & Son thinks that the Cunard liner "S. S. Franconia," leaving New York, N. Y., June 24 and due to arrive at Havre, France, July 2, will be the most convenient and satisfactory vessel for such a party, and it already has reserved some space on this boat. The services of this organization also will be available for arranging subsequent tours in Europe, and to assist in securing passports, and supplying travelers' checks. Inquiries should be addressed to Thomas Cook & Son, either in Boston, New York, or other convenient cities, as early as possible.

**Dr. W. D. Coolidge Receives Washington Award.**—Following a dinner and reception February 24, 1932, at the Hotel Sherman, Chicago, Illinois, Dr. W. D. Coolidge (A'10) associate director of the research laboratory of the General Electric Company of Schenectady, N. Y., was presented the Washington Award for 1932, "in recognition of devoted, unselfish, and preeminent service in advancing human progress." Doctor Coolidge is to be the eleventh so honored by the award commission, the first presentation being to President Hoover in 1919. Dr. H. W. Chase, president of the University of Illinois, delivered the principal address of the evening, evaluating the importance of research in the present social order. Presentation of the award was made by F. D. Chase, president of the Western Society of Engineers, which administers this award founded 16 years ago by John Watson Alvord. A personal item containing news of this award to Doctor Coolidge was given in Electrical Engineering for March 1932, p. 210–1.

# Letters to the Editor

## Discussion of "E.E." Articles Invited

Institute members and subscribers hereby are invited to discuss in these columns any of the articles appearing in Electrical Engineering. Because of the many letters received, it is not feasible to publish all, but an endeavor will be made to include those which appear to be of the most general interest. The shorter letters in general are more popular; hence conciseness is a desirable quality in all cases. Electrical Engineering reserves the right to publish letters either in full or in part.

## Edison's Self-Consistency

*To the Editor:*

With all that we are saying and reading about our beloved Edison these days, a thought came to me that is quite different from those which I have heard expressed by any one. Others may have had it and not expressed it, fearing that it was pointing out a limitation in his efforts, and ability. To me, it shows his strength of character and good judgment.

At this time, when all his admirers are vying with each other in telling of his innumerable accomplishments, it may seem disrespectful to point out a field of electrical endeavor that he consistently avoided. Edison unquestionably appreciated that to succeed in any line even he must be enthusiastic, and his early commercial fight with those who pioneered in a-c. development naturally left him without enthusiasm in this direction.

A lesser mind, as the commercial possibilities of alternating current rapidly developed, would have been tempted to join in the effort and thus share in the commercial rewards. Not so for Edison, who was always true to himself. The pioneer inventors and engineers who were working with a-c. generators, motors, and transformers would have had a formidable competitor in Edison had he decided to enter this field. He evidently decided that he had abundant opportunities elsewhere.

Is there not in this a lesson teaching the young engineer to select, if possible, lines of work that appeal to his enthusiasm rather than some that give perhaps better immediate prospect of higher financial returns? One must obtain unusual results to get superior rewards and such results are seldom attained without the assistance of enthusiasm.

Very truly yours,
WALTER S. MOODY (F'12)
(Consulting Electrical Engineer,
155 Dawes Ave., Pittsfield, Mass.)

## Diversification in Articles Commended

*To the Editor:*

The letter of protest tendered by Mr. F. G. Strong of Wethersfield, Connecticut, against the article "Nerve Injuries from Electric Shock," and appearing in Electrical Engineering (Feb. 1932, p. 138) is at once a concentrated source of astonishment and argument to me.

This attitude seems to fortify the impression gained by me during the past two years that Electrical Engineering and its predecessor, the Journal of the A.I.E.E, caters primarily to the power aspects of the electrical engineering profession. The appearance of the aforementioned article and various others of its type, not necessarily dealing with the medical aspects of electricity, has accomplished a great deal in dispelling this illusion from my mind.

With due respect for Mr. Strong's more experienced viewpoint, I nevertheless desire to commend Electrical Engineering in its display of the appreciation that the electrical engineering profession does not comprise a group of power engineers solely; but, that it also includes engineers associated with a multitudinous array of other valuable applications of that wonderful realm of reality—Electricity.

Very truly yours,
M. K. Kunins (A'32)
(Jr. U.S. Radio Inspector,
Radio Div., Dept. of Commerce, Buffalo, N. Y.)

## Unity Power Factor for Neon Tube Signs

*To the Editor:*

The article by McNeely and Law entitled "Unity Power Factor for Neon Tube Signs" and appearing in the November 1931 issue of ELECTRICAL ENGINEERING, p. 886–8, leaves the reader with the impression that the constant current circuit is the best and most economical solution, in all cases, of the problem of producing luminous tube signs with high power factor. I am writing to point out some of the reasons why this circuit has not been generally adopted.

The data given by the authors relates to the special case of a small sign with a fixed load of tubing. It is not indicated whether calculations or tests were made on larger signs and transformers with varying lengths of tubing. From the data given it appears that the tests reported were made on transformers of about 2,500 volts open circuit, delivering 15 milliamperes to the tubing. Such transformers are generally used with small window or show-case signs, and because the load taken by them is small and they are usually connected to circuits carrying a relatively large load of incandescent lighting, the power factor of the individual sign is not of great importance.

The problem of power factor is most important in the case of large signs which employ transformers of 12,000 or 15,000 volts open circuit rating, delivering approximately 25 milliamperes to the tubing. There are some problems encountered with these larger transformers which do not apply to the smaller, lower voltage units.

As the authors point out, when the constant current circuit is employed the transformer primary winding will take a substantially constant current, even when the secondary of the transformer is open-circuited. Under these conditions the entire current becomes exciting current, and the secondary voltage is limited only by the saturation of the core. Since it is not feasible to insure that the transformer may never be operated with open-circuit, the use of the constant current circuit therefore involves a serious hazard to the insulation of the transformer, and the cable, electrodes, etc., in the sign. Furthermore, the open-circuit voltage of transformers used in luminous tube signs is definitely limited by the National Electrical Code.

In determining the amount of capacity required to obtain maximum power factor correction with commercial transformers the authors have evidently connected the capacitors directly across the 110-volt circuit. They have not taken account of the generally accepted arrangement of operating the capacitor at higher voltage, using the primary winding of the transformer as an auto-transformer to obtain this voltage. Since the corrective effect of a capacitor is proportional to the square of the voltage, this arrangement results in substantial economy. A 15,000-volt 25-milliampere transformer carrying a normal load of tubing, can be made to operate at a power factor well over 90 per cent by the use of as little as 5$\mu$ of capacity operating at about 500 volts. Of course the capacitor must be suitable for use on this voltage, but most modern capacitors are, and because of mechanical limitations, very little can be gained by rating them at a lower voltage.

The fact that the installation using the constant current circuit can, and probably must, be made up of several individual devices, is likely to prove a disadvantage rather than an advantage. In the case of small window or show-case signs it is desirable that the sign manufacturer assemble the sign complete, leaving the installation job as simple as possible. In the case of large outdoor signs, this is also true, with the additional consideration that such signs frequently contain many transformers, and the use of separate reactors and capacitors installed inside the building, with separate circuits to the individual transformers would be prohibitive because of cost and complication.

A capacitor sufficient for power factor correction can be placed in the same case with the conventional transformer, with a small increase in one dimension only, providing a self-contained high power factor unit, interchangeable as to mounting dimensions with the conventional low power factor transformer.

Still another difficulty that might be expected with the constant-current circuit results from the fact that many of the higher voltage transformers are operated with the midpoints of the secondary windings grounded, in order to limit the voltage that may be applied under abnormal conditions to the tubing and other parts of the circuit. Accidental grounds may, and do, occur in the high voltage circuit. With the conventional high reactance transformer the current in the winding thus short-circuited is limited by the impedance of the transformer to a safe value. With the constant-current circuit, the primary would continue to force a definite number of ampere-turns through the secondary winding, these ampere-turns dividing between the two halves of the winding in inverse proportion to the impedances.

With one half of the winding short-circuited and the other half open-circuited or loaded, the short-circuited half would supply most of the ampere-turns, with resulting over-load and probable burn-out.

Very truly yours,
R. H. CHADWICK (A'17, M'26)
(Engineer, Transformer Division, General Electric Co., Fort Wayne, Ind.)

## Electrical Precipitation

*To the Editor:*

In connection with the article "Electrical Precipitation," by Simon and Kron, which appeared in the February issue of ELECTRICAL ENGINEERING, p. 93–5, I desire to point out a few of the results which have been obtained in the development of theory and technique by those scientists and engineers who have devoted so much effort to this art during the past twenty years, both here and abroad.

To mention but one of the many studies which have been made, E. Anderson and other engineers of the Western Precipitation Company carried on extensive experiments at Santa Cruz in 1919, using not a single size pipe electrode as reported by Simon and Kron, but 3-in., 4-in., 6-in., 9-in., and 12-in. tubes of from 5 ft. to 20 ft. in length. One of the many important results of this particular study was the development of a formula for precipitator efficiency, $\eta = 1 - K^t$, in which $K$ is a "constant." Simon and Kron use a constant $\alpha$. If we let $K = e^{-\alpha}$ we find the formula developed by them to be identical with that of Anderson and equivalent to similar formulas developed by various European investigators, notably Heinrick and Deutsch.

It must be emphasized, however, that the manner in which this formula is used is of vital importance. A point long recognized by precipitation engineers but overlooked in the reports of the Simon and Kron investigation is the fact that the "constant" $\alpha$ (or $K$) is not nearly so constant as might be desired; nevertheless, the formula is used continually in precipitator design, but always with due consideration of its recognized limitations. These limitations have made those who best appreciate them extremely hesitant in the publication of their results.

The apparatus used for the measurement of dust concentration and described by Simon and Kron, is not used in electrical precipitation investigation because of its inherent inaccuracy as a gage of dust content when there is a variation in the size of the dust particle. It has been reported by Tolman (*Journal of American Chemical Society*, V. 41, 1919, p. 307) that the light beam strength through a dust laden gas varies with the concentration of dust between limiting formulas in which, for small particles, the particle diameter appears directly as the cube, and for the large particles inversely as the first power. The Tyndall beam type of instrument is therefore of little value in the comparison of inlet and outlet concentrations if there is any marked change in the dust particle size between the two points of measurement. An electrical precipitator will produce such a change in dust particle size to a very marked degree, especially in the case of particles of the kind used by Simon and Kron.

This fundamental characteristic of the measuring device is doubtless responsible for the difference which exists between the conclusions reached by Simon and Kron and the facts established by engineers and scientists who, under the auspices of Lurgi Apparatebau-Gesellschaft, Siemens-Schuckertwerke, Lodge-Cottrell, Ltd., Western Precipitation Company, and Research Corporation, have been working on this problem for more than a score of years. I refer especially to the statement that efficiency is a positive exponential function of the current and the statement that the voltage, in so far as it affects the electrical field, has little effect on efficiency.

Very truly yours,
J. C. HALE (A'10, M'29)
(Electrical Engineer, Research Corp., Bound Brook, N. J.)

## Has Man Benefited by Engineering Progress

*To the Editor:*

Responding to the invitation to submit comments on the question "Has Man Benefited by Engineering Progress" I am impressed by the letter of Professor Rittenhouse, in ELECTRICAL ENGINEERING, January 1932, p. 59, as discussion of the question can run riot in the absence of more exact definition. If man is benefited by cheap bathtubs, talkies, radio crooners, automobiles, etc., there is no room for discussion. Science and engineering gave these and some others less pleasant to contemplate. If, however, benefit to mankind results from cultivation of what is beautiful, using the word in its broadest sense, and suppression of what is ugly in the world and in human relations, the question becomes debatable. It might be possible to prepare an impressive argument to show that man would be better off if every child born with a scientific mind had died in infancy. What is the formula for human benefit? *Homo sapiens* is treated in the mass in government statistics, but individually he is everything from the noblest to the lowest of earthly creatures. Anything that promotes a higher average of character and mentality would be a benefit, and perhaps engineering has helped in this direction.

Mr. Kohn wants engineers to "work out a new vision of human relations" but that does not seem to be a hopeful job for the profession. I wonder if a brand new engineering vision would be more popular than that given in "The Sermon on the Mount." From a practical point of view, would it not be better to do less dreaming about a new social scheme, and more hard work to make the existing scheme better?

The membership of our national organizations constitutes a great body of skilled engineers and a host of men of wide practical business experience. They and their predecessors have given the United States the machine age civilization that is so much admired. They should be worshipped as were the priests of Ammon; but on the contrary the public and the politicians treat them rather like djinns ordered out to perform miracles, which, these being done, are stored away in bottles. If the symposium includes the question as to what engineers should do to benefit mankind, then I suggest that American engineers try to break out of the bottle and take their proper place in public affairs. Vast sums have been, are being, and will be, squandered on governmental projects that come directly within the province of engineers. The people naturally cannot form an intelligent opinion of such undertakings, those who should guide them are ignored, and the political promoters have their way. I cannot do better than to refer to the address on this subject by W. S. Lee, published in ELECTRICAL ENGINEERING for August 1931, p. 641–2. It seems to be a sad fact that the engineer has no real standing with the American public. True, we have an engineer as President of the United States; but did that fact count in his election? I doubt it, for he gets no consideration as such, and if instead he had been a first-class politician, he would probably have had better support. If engineers enjoyed public esteem, would it not have been a natural procedure to leave, so far as possible, any purely engineering question to the judgment of an engineer president? The prolonged inane discussions of Muscle Shoals in Congress is a case in point. Any competent engineer could have cut that discussion short with a few facts; but none was given the opportunity. This country has the most highly developed electric power supply in the world, and consequently, an abundance of experts on the subject; yet the United States Senate seriously discussed supplying electricity to the public from that chunk of concrete in the Tennessee River, where the flow is as unreliable as German reparations. Public waste makes private want, and engineers can benefit mankind as represented by the people of the United States if they can find a way to establish an influence in such public affairs as are in their own field, and respecting which they only are competent to form sound decisions. I do not know how this can be done, but it is well worth our attention both as engineers who detest economic crimes and as patriotic citizens. It might be worth while first to try to discover why engineers are not consulted in advance on government projects, as they are in similar private undertakings? Perhaps it is because our profession is too modest or too timid to proclaim the truth so that the taxpayer may at least know in advance what is coming to him. Mr. Hoover recently said that our governments, federal, state, etc., are "engaged in constant attempt to solve a multitude of public relationships to these tools which the engineers . constantly force to the very doorstep of the government;" to which he added "These problems of public relations are unsolvable without the technical assistance of the engineer himself." In concluding his address the President of the United States insisted that engineers have the obligation to contribute to the public service. If we have the ability, persistence, judgment, and perhaps self-sacrifice to take on the obligation, we may then benefit our countrymen, if not all mankind.

Very truly yours,
F. V. HENSHAW (A'89, M'95, Member for Life) (Wood, Struthers, & Co., 20 Pine St., New York, N. Y.)

### Speakers for Washington Bicentennial Celebrations

During the remainder of 1932, many celebrations will be held in commemoration of the 200th anniversary of the birth of George Washington. The American Engineering Council is preparing a list of speakers who are especially qualified to address engineering groups upon the engineering features of George Washington's career, and has requested the Institute to supply some names.

Members of the Institute who would be willing to prepare such addresses to be delivered in their localities are requested to send prompt notification to Institute headquarters, 33 West 39th St., New York, N. Y.

**Specifications for Electrical Heating Elements.**—The American Society for Testing Materials is seeking comments on two recently adopted specifications, as follows: tentative specifications for "Drawn or Rolled Alloy, 80 per cent Nickel, 20 per cent Chromium, for Electrical Heating Elements" (B82–31T) and "Drawn or Rolled Alloy, 60 per cent Nickel, 15 per cent Chromium, and Balance Iron, for Electrical Heating Elements" (B83–31T). Comments on tentative method of "Test for Determining the Temperature-Resistance Constants of Resistance Alloys" (B84–31T) are also requested. Communications relative to the above should be addressed to R. E. Hess, American Society for Testing Materials, 1315 Spruce Street, Philadelphia, Pa., from whom copies of the specifications may be obtained.

## American Engineering Council

### Study Being Given Muscle Shoals Legislation

Dr. H. E. Howe of Washington, D. C., Prof. Charles F. Scott (A'92, F'25, HM'29, and past-president) of Yale University, New Haven, Conn., and J. Dyer of Nashville, Tenn., have been appointed by the American Engineering Council to study the Muscle Shoals measure introduced in the House by Representative E. B. Almon of Alabama.

The purpose of the Almon bill is, first, to aid American agriculture and to provide for national defense by the employment of the Muscle Shoals project, privately operated primarily for the production of fertilizer; and second, to make available for the production of chemical products any surplus of the Government owned resources.

The bill would create the Muscle Shoals Corporation of the United States, the directors of which would be authorized to lease for not more than fifty years the Muscle Shoals properties of the government. It also provides for an appropriation of $5,000,000 to build Cove Creek Dam.

The American Engineering Council, it was also announced, is opposed to the Muscle Shoals legislation sponsored by Senator George W. Norris of Nebraska "to provide for the national defense by the creation of a corporation for the operation of the government properties at and near Muscle Shoals in the state of Alabama, to authorize the letting of the Muscle Shoals properties under certain conditions, and for other purposes." This resolution was reported in the Senate, March 9, 1932, by the committee on agriculture and forestry. A similar resolution by Representative W. F. James of Michigan has been referred to the committee on military affairs of the House. These resolutions are identical and contain approximately the same proposals as the legislation which passed the Seventy-first Congress and was vetoed by the President.

## Engineering Foundation

### Plans for Study of Industrial System Discussed

At a dinner meeting of the Engineering Foundation on February 18, 1932, in New York, N. Y., consideration was given to plans for a study of the industrial system. Representatives from the American Engineering Council, the planning committee, United Engineering Trustees, Inc., and the Engineering Foundation, together with several special guests, brought the total attendance to 37.

For several years there has been a growing sense of obligation among members of the Engineering Foundaton to undertake from the engineer's point of view, research bearing upon economic and other humanistic problems. In September 1931, the United Engineering Trustees, Inc. submitted a proposal for a study of the industrial system to the Foundation, and the latter has since been giving the subject earnest consideration. The planning committee appointed is cooperating with the American Engineering Council.

Valuable suggestions were offered during the discussion at this meeting, and the need for a thorough study was emphasized. Definite suggestions were made and the desirability of cooperating with members of other professions was brought out. However, the valuable background of thought, habit, and experience of the engineer should be the center around which this cooperation should be built up. The necessity for courage and determination in the study of industrial problems was emphasized by several of the discussers, all of whom agreed as to the tremendous benefits which may be secured from such a study.

# Annual Report Issued by United Engineering Trustees, Inc.

IN THE annual report of United Engineering Trustees, Inc., for 1931, submitted by John V. N. Dorr, president, and Alfred D. Flinn, secretary, it is pointed out that the assets for which the corporation is responsible total $3,425,957.52, exclusive of the library and the John Fritz Medal fund. The report also mentions that outstanding among events of 1931 was the fourth gift of Ambrose Swasey, founder of the Engineering Foundation; this gift of $250,000 raised the total to three-quarters of a million dollars.

Through the will of E. H. McHenry, a well-known consulting engineer, late of Philadelphia, Pa., Engineering Foundation benefited to an additional amount estimated at approximately $400,000.

Early in November, United Engineering Trustees, Inc., consented to serve as treasurer and accountant for the Professional Engineers Committee on Unemployment. It is continuing to perform these services.

The development committee in December submitted a full report of its extensive studies for providing needed additional accommodations for the engineering societies. The Engineers' Club joined in this work which was devoted largely to a scheme for an "engineering center" but owing to business conditions no active steps are now feasible.

Through recommendation of the Trustees, Engineering Foundation in examining the possibilities of an engineering study of the industrial system. In passing to the summary of the financial report, it is worthy of note that all departments again closed the year without deficits.

### Summary of 1931 Financial Report

| | | |
|---|---|---|
| **Operation of Building** | | |
| Credit Balance January 1, 1931 | $10,636.73 | |
| Less Adjustment 1930 | −25.00 | -$10,611.73 |
| Building Revenue 1931 | 126,837.37 | |
| Building Expenditures 1931 | 115,546.96 | 11,290.41 |
| Total | | $21,902.14 |
| Annual Payment to Dep. and Renewal Fund | $12,000.00 | |
| Payment to Reserve for Future Fire Insurance | 1,550.00 | 13,550.00 |
| Credit Balance December 31, 1931 | | $8,352.14 |
| **Operation of Library** | | |
| Maintenance Revenue | $50,674.96 | |
| Maintenance Expenditures | 52,011.70 | |
| Debit Balance for year 1931 | −1,336.74 | |
| Credit Balance from preceding years | 5,688.95 | |
| Total Credit Balance December 31, 1931 | | $4,352.21 |
| Service Bureau Revenue | $17,031.56 | |
| Service Bureau Expenditures and Adjustments | 17,422.17 | |
| Debit Balance for year 1931 | −390.61 | |
| Credit Balance from preceding years | 4,733.96 | |
| Total Credit Balance December 31, 1931 | | $4,343.35 |
| **Funds and Property** | | |
| Funds held by U.E.T., Inc. Dec. 31, 1931 (book value) | | |
| Depreciation and Renewal Fund | | $303,397.14 |
| General Reserve Fund | | 3,934.40 |
| Engineering Foundation Fund | | 529,283.65 |
| Engineering Foundation Fund (4th Swasey Gift) | | 253,696.50 |
| Henry R. Towne Engineering Fund | | 50,115.63 |
| Library Endowment Fund | | 174,544.32 |
| Edward Dean Adams Fund | | 100,000.00 |
| Total | | $1,414,971.64 |
| Real Estate owned, cost to Dec. 31, 1931 | | $1,987,793.92 |
| Operating cash and petty cash | | 10,092.63 |
| Accounts Receivable | | 5,585.83 |
| Endowment Committee Loan Receivable | | 1,700.00 |
| Unexpired Fire Insurance Premiums | | 1,213.50 |
| Fire Insurance Fund | | 4,600.00 |
| Total Property which U.E.T., Inc. owns or holds | | $3,425,957.52 |
| Value of Library (as appraised approximately for Insurance) | | $483,000.00 |
| John Fritz Medal Fund (Custodian) | | 3,500.00 |

# Election Held by Engineering Foundation

At its annual meeting February 18, 1932, the Engineering Foundation board reelected as its chairman H. Hobart Porter (A'96, M'12, Life Member) president of the American Water Works and Electric Company, Incorporated, New York, N. Y.; George W. Fuller, consulting engineer, former vice-president of the American Society of Civil Engineers, New York, N. Y., and a member of the firm of Fuller and McClintock, was made vice-chairman. Second vice-chairman is C. E. Skinner (A'99, F'12) president of the A.I.E.E., and assistant director of engineering for the Westinghouse Electric and Manufacturing Company, E. Pittsburgh, Pa. George D. Barron, mining engineer, of Rye, N. Y., and D. Rovert Yarnhall, of Philadelphia, Pa., vice-president of the American Engineering Council, were elected to the executive committee. Dr. A. D. Flinn continues as secretary and director.

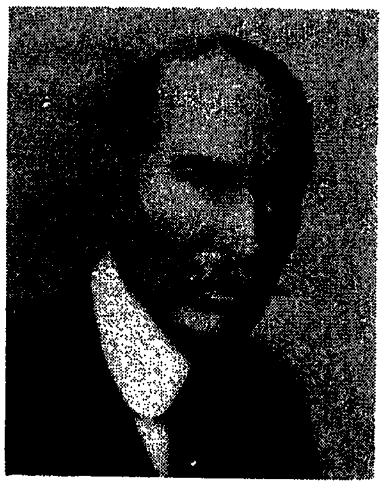
New members and reelected members of the Engineering Foundation board whose terms began at the annual meeting on February 18, 1932, are E. De. Golyer, New York, N. Y.; H. P. Charlesworth (F'28) representing the A.I.E.E., New York, N. Y.; E. R. Fish, Hartford, Conn.; G. G. Crawford, Pittsburgh, Pa.; H. Hobart Porter (M'12) New York, N. Y.; and H. A. Kidder (F'29) New York, N. Y.

# Personal

A. S. MILLER (A'08, F'12) vice-president of the Bartlett Hayward Company, engineers, New York, N. Y., at the January 14, 1932 meeting of the Engineering Societies Library board was reelected chairman and W. I. SLICHTER (A'00, F'12) was made vice-chairman. Mr. Miller is a native of Richmond, Virginia; since his graduation from Stevens Institute of Technology in 1888 he has had extensive experience in public utilities. In 1911, with Dr. A. C. Humphreys he formed the consulting firm of Humphreys and Miller, Incorporated, an activity which he continued until 1918 when he became vice-president of the Bartlett Hayward Company. He was appointed to the library board by the American Society of Mechanical Engineers. Professor Slichter, already well known in the annals of the A.I.E.E. as manager (1918–22) vice-president (1922–24) and an active worker on several of its committees, was born in St. Paul, Minn. Immediately after graduation from Columbia University in 1896 he entered the employ of the General Electric Company at Schenectady as a student. Shortly thereafter he was transferred to the office of Dr. C. P. Steinmetz to engage in experimental work, tests, and calculations on a number of subjects. For several years he served the Society of Engineers of Eastern New York as treasurer. His contributions to technical literature have been many.

VANNEVAR BUSH

**Dr. Vannevar Bush** (A'15, F'24) since 1923 a member of the faculty of electrical engineering of Massachusetts Institute of Technology, Cambridge, Mass., recently was elevated to his new office of vice-president and dean of engineering, according to appointments announced March 10, 1932. He is a native of Everett, Mass., a graduate of Tufts College (1913), and holds a degree of doctor in engineering from Harvard University and from M. I. T., where his work has been noteworthy in research achievements and contributions to technical education. He has been interested particularly in the design of scientific calculating instruments, and for the development of the product integraph in 1928 was awarded the Levy Medal of the Franklin Institute. Not long since he won recognition for his design of an intricate calculating machine called the differential analyzer, which greatly increases the accuracy and speed of engineering calculations. He is also known for his contributions to the development of vacuum tubes and his investigations in electric power transmission. Under his direction at M. I. T. has been built another instrument known as the network analyzer, a device upon which a power network covering several states may be reproduced accurately and operating characteristics studied under most satisfactory conditions. Important branches of study carried on by Doctor Bush have been those of transients in machines, and dielectric phenomena. His career as a teacher has been no less notable than has his work in research; he has been professor of electrical transmission and for sometime was in charge of graduate study and research in the department. Early in his career he held a position in the test department of the General Electric Company, returning to Tufts College as an instructor in mathematics; from this position he was subsequently advanced to that of assistant professor of electrical engineering. Following the World War during which he did valuable research work on the detection of submarines for a special board of the United States Navy, he was consulting engineer for the American Radio and Research Corporation. He is a director of the Spencer Thermostat Company, Cambridge, Mass., and of Raytheon Incorporated of Newton, Mass. He is a Fellow of the American Academy of Science, and of the American Physical Society; a member of the Society for the Promotion of Engineering Education, and the author of numerous contributions to scientific and engineering literature. The book "Principles of Electrical Engineering" written in joint authorship with Professor W. H. Timbie is probably one of the most widely used books in its field.



H. H. PORTER

**H. Hobart Porter** (A'96, M'12) president of the American Water Works and Electric Company, Incorporated, New York, N. Y., and a Life Member of the Institute, was reelected chairman of the Engineering Foundation at its annual board meeting Feb. 18, 1932. The Foundation is the research organization of the national societies of civil, mechanical, mining and metallurgical, and electrical engineers, with headquarters in the Engineering Societies Building, 33 West 39th Street, New York. Mr. Porter, who is chairman also of the board of the West Penn Electric Company and a director of numerous railroad and public utility enterprises, is a former trustee of Columbia University and a former president of the University Club, New York City. As a member of the firm of Sanderson and Porter, New York, he was engineer of the large hydroelectric development in California of the Stanislaus Electric Power Company, later known as the Sierra and San Francisco Power Company. Power was transmitted 140 miles at 110 kv. to serve the United Railways of San Francisco. This was one of the first 110-kv. transmission lines over so great a distance and involved many original problems. For some years Mr. Porter was one of the consulting engineers for the Interborough Metropolitan Railway Company; his work on many important investigations and as an engineer in charge of large operations was given high commendation, and products of his professional ability have been demonstrated in design and construction developments in many states: in the hydroelectric development for the Inland Empire Railway System, Spokane, Washington, the Twin-branch power plant and transmission system for the Indiana and Michigan Electric Company, South Bend, Ind., the steam power plant and transmission system for the New Hampshire Traction Company, Portsmouth, N. H., two steam power plants for the New Orleans Railway and Light Company, New Orleans, La., and several Connecticut developments of important tramways.

**Gerald Deakin** (A'07, M'13) who was first assistant chief engineer of the International Telephone and Telegraph Company, New York, N. Y., now is in London in the capacity of vice-president and European technical director of the International Standard Electric Corporation.

**Walter Steinkamp** (A'26) previously district manager of the Picker X-Ray Corporation, Buffalo, N. Y., recently became secretary and general manager of James Picker, Inc., and Waite & Bartlett X-Ray Manufacturing Company, both of Cleveland, Ohio.

**H. L. Olesen** (M '27) formerly sales and contact engineer of the Jewell Electrical Instrument Company, Chicago, Ill., now is manager of the radio sales division of the Weston Electrical Instrument Company, Newark, N. J., in charge of the combined radio lines of the Jewell and Weston companies.

**H. N. Hardsog** (A'25) in the past designing engineer with the Narragansett Electric Company, Providence, R. I., on February 8, 1932, became power engineer for the Fall River Light Company, Fall River, Mass., both companies being controlled by the New England Power Engineering and Service Corporation.

**Stuart Wilder** (A'02, M'13) vice-president of the Westchester Lighting Company, Mount Vernon, New York, and a past-president of the Empire State Gas and Electric Company, recently was chosen a vice-president of the Yonkers Electric Light and Power Company. Mr. Wilder's record with the Westchester Lighting Company dates from 1903 when he joined the company as assistant chief engineer of the electrical department.

**G. B. Kirkwood** (A'25) previously district sales manager of the New York, N. Y., sales office of the Pacific Electric Manufacturing Corporation, has been transferred to Los Angeles, Calif., to succeed **L. C. Williams** (A'15, M'26) district manager of the latter office, who has been quite ill of late. Mr. Kirkwood has been engaged in the design and sale of high tension switchgear and protective devices with the Pacific Electric Manufacturing Corporation since 1913, having served successively as shop workman, draftsman, chief draftsman, on costs and estimates, and since 1924 district sales manager. He has been in the San Francisco, Calif., Los Angeles, Calif., Chicago, Ill., Gary, Ind., New York, N. Y., and now the Los Angeles offices of the company.

A. K. MacNaughton (A'21, M'26) who has been with the Georgia Power Company, Atlanta, Ga., as electrical engineer, now has joined the Commonwealth and Southern Corporation, Alabama Power Building, Birmingham, Ala.

J. L. Sherwin (M'30) who has been serving the H. K. Ferguson Company, at Cleveland, Ohio, as electrical engineer, now has gone into business for himself in that city, and will specialize in power plant and industrial engineering reports and design.

A. E. Pope (A'07) vice-president of the New England Power Association, Boston, Mass., has been elected president of the New England Power Company, Worcester, Mass., the association's principal wholesale generating and distribution unit in central New England.

U. N. Halliday (A'28) who has been district sales manager of the Portland territory of the Pacific Electric Manufacturing Corporation, is being transferred to Salt Lake City, Utah, to open a new branch sales office there. His territory will consist of Utah, Idaho, Montana, Wyoming, and Colorado.

E. H. Rosenquest (A'03) president of both the Westchester Lighting Company, Mount Vernon, N. Y., and the Bronx Gas and Electric Company of New York City, and recently elected president of the Yonkers Electric Light and Power Company, was made a director of the United Electric Light and Power Company at a recent meeting of its board.

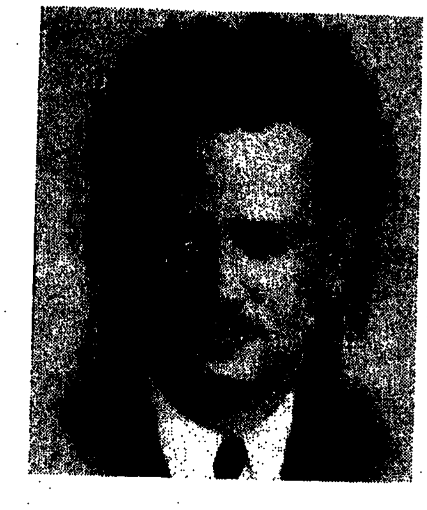
C. H. Cutter (A'28) formerly district sales manager for the Pacific Electric Manufacturing Corporation at Seattle, Wash., has recently been placed in charge of the Portland, Ore., territory for the company. His headquarters will remain at Seattle. Mr. Cutter has been with the Pacific Electrical Manufacturing Corporation since 1921, having served as assistant to the superintendent, purchasing agent, and advertising manager previous to becoming district sales manager.

Kline Gray (A'24) who has been handling the sale of Ward Leonard products for the past seven years with the Westburg Engineering Co., Chicago, Ill., has been appointed Chicago district manager of the Ward Leonard Electric Company. In an effort to better serve this important territory, F. E. Beede, sales engineer of the Ward Leonard company, will be transferred from the factory organization to the Chicago staff. This change has been occasioned by the appointment of P. A. Westburg (A'07, M'16) as Chicago district manager of the Weston Electrical Instrument Corporation.

W. A. DelMar (A'06, F'20) chief engineer of the Habirshaw Cable and Wire Corporation, Yonkers, N. Y., Prof. W. I. Slichter, of Columbia University, W. B. Jackson (A'97, F'13) rate engineer, New York Edison Company, New York City, and W. S. Barstow (A'94, F'12) president of W. S. Barstow and Company, New York, N. Y., have been elected to serve as A.I.E.E. representatives on the library board of the Engineering Societies Library for the year 1932.

J. J. Orr (A'30) plant engineer of A. J. Brandt, Incorporated, Detroit, Mich., has removed to New York City, where he is electrical engineer for the United States Rubber Company. Mr. Orr has specialized in industrial power engineering and supervised the design and installation of the complete electrical system in the General Motors plant at Pontiac, Mich., the American Austin Car Company at Butler, Pa., and the "Amo" Auto Works at Moscow, U. S. S. R.

H. R. Woodrow (A'12, F'23) at a recent election of officers for the Brooklyn Edison Company was made vice-president in charge of electrical operations. He is a native of Rock Rapids, Ia., and a graduate of the University of Illinois (1909). Prior to 1917, Mr. Woodrow was assistant chief electrical engineer of the New York Edison Company with which he has been identified since 1911. As an assistant to Mr. Philip Torchio he was associated with various developments and investigations, and in his appointment as assistant chief electrical engineer he kept closely in touch with the design and operation of all generating and substations of the company. In 1922 he became assistant electrical engineer of the Brooklyn Edison Company, associated with J. C. Parker, recently elected to the presidency, and in this connection demonstrated extraordinary practical judgment, analytical ability and initiative in connection with the electrical design of generating stations, transmission systems, substations, and distribution systems. He has always taken a very active interest in the field of protective devices and for five years served on the Institute's committee on protective devices. He has served also on the A.I.E.E. membership, meetings and papers, standards, and power transmission and distribution committees, the last of which he was chairman 1928–30; at present he is a director and serving also on the publication committee. Mr. Woodrow was identified in a consulting capacity in the design of the Trenton Falls and Washington Street station at Dayton, Ohio, the Williamsburg station of the Brooklyn Rapid Transit Company, and the government plant at Nitro, Va. His transfer to the grade of Fellow endorsed by Benjamin G. Lamme included the statement, "I have been in direct contact with Mr. Woodrow's work for many years in engineering problems requiring advanced knowledge of electrical theory and practise in the application of electrical apparatus, and have found him a man of very great knowledge and ability."



H. R. WOODROW

G. L. KNIGHT

G. L. Knight (A'11, F'17) mechanical engineer of the Brooklyn Edison Company, Brooklyn, N. Y., for many years, and prior to his appointment as such, design engineer for that company, was chosen by recent election to be its vice-president in charge of mechanical operations. Born at Haddonfield, N. J., Mr. Knight was graduated from Drexel Institute in both mechanic arts (1898) and electrical engineering (1900). In 1902 he was manager of the Walker Electric Company of Philadelphia, Pa. For two years he was chief draftsman of the New York Edison Company prior to his transfer to the Brooklyn Edison Company in 1905 in like capacity. In 1908 he was made designing engineer, the position he occupied until 1924 when he became mechanical engineer. He has done no inconsiderable special electrical, mechanical, and civil engineering work in connection with the construction of large central stations, from the laying of their heavy foundations and condensing tunnels straight through to the completion of stations ready to operate, and the complete design and construction of substations, storage yards, and office buildings. His committee work with the Institute has been abundant; he has served on the following committees: standards 1914–25; board of examiners, 1922–4, 1928–9; finance, 1922–8; executive, 1923–8; headquarters, 1923–8; coordination of Institute activities, 1923–6, 1927–8; Edison Medal, 1926–8; meetings and papers *ex-officio* 1927–8; and power generation, 1927–9. He was a member of the U.S. national committee of the International Electrotechnical Committee, 1923–6; and a member of the board of trustees of the United Engineering Trustees, 1926–31. Besides his committee work, Mr. Knight has served the Institute as a manager 1922–6, and a vice-president, 1926–8.

Harry B. Smith (A'28) who has been serving the Northern Electrotype Company of Detroit, Michigan, as mechanical engineer, has been made a vice-president of the American Electrotype Company, also in Detroit.

H. S. Falk (A'08) vice-president and general works manager of the Falk Corporation of Milwaukee, Wis., was elected a director of the Heil Company of that city at a recent meeting of the board.

H. M. Brinckerhoff (M'26) of the firm of Parsons, Klapp, Brinckerhoff and Douglas, of New York, N. Y., has been appointed a member of the city plan commission of Englewood, N. J.

R. C. Young (A'29) previously district manager for the Kuhlman Electric Company, Atlanta, Ga., has been transferred to the Chicago, Ill., territory of the company where he will continue as district manager.

F. J. Cornford (A'23) who was construction superintendent for the Ohio Power Company, Philo, Ohio, now is construction engineer for the Scranton Electric Company at Pittston, Pa.

D. C. Harker (A'27) who was a general engineer for the Westinghouse Electric and Manufacturing Company, Detroit, Mich., now has joined the Hudson Motor Car Company in that city as engineer.

G. J. Lexa (A'20) electrical engineer, Harnischfeger Corporation, Milwaukee, Wis., recently changed his affiliations and became electrical engineer of the Lakeside Bridge and Steel Company of that city.

A. E. Waller (A'12, F'21) priorly associated with the General Cable Corporation, now has joined the Sundh Electric Company of Newark, New Jersey, as sales engineer.

P. J. Ost (M'23) who served the City of San Francisco as its chief electrical engineer now has taken a similar position with the Public Utilities Commission of San Francisco, Calif.

F. W. Willis (A'04, F'19) who served as local Honorary Secretary of the Institute for India from 1925 to 1930, has retired from active service in India and is now residing in Auckland, New Zealand.

# Obituary

Frank George Baum (A'99, F'14) consulting engineer, vice-president of the Institute 1906–8, and a pioneer in hydroelectric and transmission developments on the Pacific Coast, died at Redding, California, his place of residence, March 14, 1932. He was 61 years of age. Mr. Baum was born at Ste. Genevieve, Missouri; his batchelors degree in electrical engineering was conferred upon him by Stanford University at the time of his graduation in 1898. In 1899 he received his E.E. degree at the completion of a year spent at the same institution as assistant in electrical engineering. To bring the consumer and producer together is a most interesting economic problem of any age, and this was the work which Mr. Baum made the keynote of his remarkable career. He was employed first by the Standard Electric Company of California. Blessed with high inventive genius, he was enabled to solve many problems in the production and transmission of power. In the Piedmont station (Calif.) he was the originator of the compounding of synchronous motor-generator sets, whereby the compounding of the exciters was taken from the shunt on the busbar of the railway load, changing the power factor of the motors and keeping the potential of the substation nearly normal. This was in line with his much later invention, the synchronizing condenser and regulator, announced in 1927, a device which solved the problem of economical transmission of large amounts of electrical power over distances of several hundred miles, dividing the lines into sections of from 100 to 200 miles linked by rotary regulators or condensers, each transmitting the current onward with small losses. W. S. Rugg (A'02, M'13) vice-president of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., by which the patents were acquired is quoted as asserting that "by means of it the capacity of a given line can be increased 75 per cent at a cost not exceeding 20 per cent of the original cost of the line, making possible the economical transmission of power from distant waterfalls and ultimately making possible for sparsely settled outlying districts and farms almost anywhere in the United States a supply of electric power." From 1900 to 1902 he was instructor in electrical engineering at Stanford University at the same time doing special work in electrical transmission for the Bay Counties Power Company and others. He then became an electrical engineer of the California Gas and Electric Corporation, and from 1907 on practised consulting engineering with special reference to hydroelectric developments. The conception and much of the engineering outline of the Pit River power developments for the Pacific Gas and Electric Company were attributable to Mr. Baum's foresight and appreciation of possibilities. He designed Hat Creek Nos. 1 and 2, Pit River No. 1, the 220,000-volt Pit transmission line, and the great Vaca substation at the receiving end. His work during the years 1926–8 was developing insulators and regulations systems outlined in his paper "Voltage Regulations and Insulation of Large-power Long-Distance Transmission System" for which he received the Institute's 1921 yearly transmission prize. For the betterment of social conditions Mr. Baum believed firmly in the linking of business enterprise with scientific thinking, his expressed thought being that "the best control of a utility is that which develops an eagerness and ability on the part of the company to furnish service and an equal eagerness and ability on the part of the consumer to purchase the service. He was the author of the books "Alternating Current Transformer" and "Atlas of U. S. A. Electric Power Industry." Several years were spent studying the European electrical power industry, and he completed a voluminous report on the enlargement and extension of one of Germany's largest electric utilities. His international reputation took him into both France and Germany as a consultant for power concerns, and upon his return to California he established extensive laboratories in the mountains of the northern part of the state for a further study of electrical engineering.

Engelhardt Wilboren Holst (A'05) consulting engineer with offices in Boston, Mass., died at his home in Concord, N. H., February 1, 1932. He was 61 years of age. A native of Christiania, Norway, Mr. Holst received his early technical training there, graduating with an M.E. degree. He came to the United States and engaged with the General Electric Company of Chicago in the summer of 1895, starting with the General Electric test course and subsequently being promoted to the superintendency of the company's repair shop. Two and a half years were spent with the company's Canadian office and one year in travel. In 1905 he took the position of superintendent of equipment for the B & N and Old Colony Street Railway Company, Boston, Mass., and later assumed like duties with the Bay State Railway Company, also of Boston. The Boston consulting engineering practise in which he was engaged at the time of his death was established in 1920.

Isabelle Conkling Conlin (nee Williams) (A'21) of Hempstead, N. Y., died January 23, 1932; she had been ill for several years. Born in Brooklyn April 6, 1894, Mrs. Conlin received her early education in the New York public schools. In 1917 she was graduated from Barnard College, the Columbia University School for women in New York City. She immediately became associated with the Western Electric Company as engineering assistant in the physical laboratory and in 1920 was made laboratory engineer supervising an electrical measurement group, and establishing for herself a creditable record of achievement and capability.

Jeremiah Joseph Kennedy (A'00, M'02) consulting engineer, Brooklyn, N. Y., died February 15, 1932. He was born in Philadelphia, Pa., October 22, 1864, and was educated in the private schools of that city. His technical education also was obtained under private tutelage and included chemistry, and civil, mechanical, and electrical engineering, this last subject receiving the major part of his attention. The first of the year 1882 he joined the Norfolk and Western railroad as a rodman, returning in the fall of that year to study higher mathematics and civil engineering.

The following June he became principal assistant to General Russell Thayer, in civil engineering; for another year, still pursuing his studies, he spent considerable time visiting mines, various works in operation, and inspecting important structures. July 1885, he was given charge of various field surveys in Pennsylvania and Virginia, and in August became chief engineer of the Lynchburg Iron Company operating iron mines and constructing railroads. During the major part of 1886 he served as principal assistant to General Russell Thayer, but in November 1888, he turned his attention to electrical engineering and six years later became principal assistant engineer to J. G. White, president of J. G. White & Company of New York and Baltimore; three years later he was made chief engineer. With this company his work included cable and electric railway construction; the design and construction of subways in Baltimore; design, construction, and operation of electric light and power plants; the design and construction of substations for the Toledo and Detroit railway, and for the Niagara Falls-Buffalo transmission line. Previous to this he was for two years chief engineer of Atlantic Highlands, Red Bank, and Long Branch Electric Railway and for over a year he filled the position of chief engineer and superintendent of the Borough of Manhattan Electric Company, New York City, for the purpose of reconstructing and reorganizing its plants, and subsequently to plan and install extensions; it was while filling these positions Mr. Kennedy secured his permanent position as chief engineer of the J. G. White and Company. Mr. Kennedy was one of the first engineers to appreciate the advisability of making parts and flywheels of engines used in parallel operation of such weight that they would have no tendency to vibrate in harmony with the electrical oscillations. His attack of any engineering problem was energetic and intelligent and he was an enthusiastic and indefatigable worker. Among his other achievements in the line of electrical design and construction were the Detroit and Lake Orion Railway, Detroit, Mich., the power station at Perth, West Australia, and the design of a proposed central station for the Third Avenue railway of New York City.

# Local Meetings

## Past Section Meetings

**Atlanta**

Audible Light, by John B. Taylor, Genl. Elec. Co. Demonstrations. Feb. 15. Att. 850.

**Chicago**

Electric Motor Control, by G. C. Wilms, Bradley Mfg. Co. Joint meeting with Western Soc. of Engrs. Feb. 15. Att. 178.

**Cincinnati**

Electric Shock, by Dr. W. B. Kouwenhoven, Johns Hopkins Univ., vice-pres. A.I.E.E. Dinner. Feb. 25. Att. 85.

**Cleveland**

Demonstration and lecture by S. P. Grace, asst. vice-pres., Bell Telephone Labs., Inc. Joint meeting with Advertising Club, Chamber of Commerce, Cleveland Engg. Soc., and Elec. League. Feb. 3–4. Att. 5,000.

Field Studies of Lightning Protection on Distribution Circuits, by K. B. McEachron, Genl. Elec. Co. Feb. 18. Att. 107.

**Dallas**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Feb. 26. Att. 127.

Construction Progress at the Hoover Dam, by S. O. Harper, U.S. Bureau of Reclamation. Demonstrations. Dinner. Feb. 10. Att. 60.

**Detroit-Ann Arbor**

Fundamental Physical and Psychological Aspects of Television, by J. O. Perrine, Am. Tel. & Tel. Co. Demonstrations. Joint meeting with Detroit Engg. Soc. Feb. 16. Att. 650.

**Erie**

History and Development of Motor Driven Electric Clocks, by Alvan Fisher, Warren Telechron Co. Feb. 16. Att. 100.

**Fort Wayne**

Radio Interference, by Arthur B. Smith, Assoc. Elec. Labs. Discussion. Feb. 11. Att. 90.

**Houston**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Dinner. Feb. 24. Att. 85.

**Indianapolis-Lafayette**

Electrons at Work and at Play, by Dr. Phillips Thomas, Westinghouse Elec. & Mfg. Co. Demonstrations. Feb. 10. Att. 340.

**Ithaca**

Protection of Distribution Circuits and Apparatus, by B. B. McEachron, Genl. Elec. Co. Feb. 19. Att. 124.

**Kansas City**

Light and Architecture, by A. L. Powell, Genl. Elec. Co. Dec. 28. Att. 110.

Control of Smoke Nuisance in Cities, by A. S. Longsdorf, Wash. Univ. Joint meeting with A.S.M.E. Sec. Jan. 15. Att. 85.

**Los Angeles**

Overseas Telephone Services of the Bell System, by W. H. Harrison, Am. Tel. & Tel. Co. Demonstrations. Feb. 9. Att. 106.

**Louisville**

Lightning—Recent Investigations and Findings, by F. W. Peek, Jr., Genl. Elec. Co. Demonstrations. Feb. 19. Att. 169.

**Lynn**

America Steps Ahead With the Akron, by R. H. Smith, M.I.T. Movies. Feb. 10. Att. 1,054.

Mercury Vapor Turbines, by L. A. Sheldom and B. P. Coulson, Genl. Elec. Co. Feb. 24. Att. 500.

**Memphis**

Development of Vocational Guidance, by J. L. Highsaw, Memphis Tech. High Sch. Feb. 9. Att. 35.

**Mexico**

Some Recent Developments and Trends in Electrical Machinery and Apparatus, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Demonstrations. Feb. 17. Att. 70.

Banquet. Feb. 18. Att. 58.

**Minnesota**

Research Work in Laboratory Developments, by H. D. Sanborn, Genl. Elec. Co.; The Challenge to the American Business Man, by J. B. Chapple, Ashland Daily Press. These talks were given before the convention of the Minnesota Federation of Architectural and Engg. Societies. Feb. 26–7. Att. 100.

**Montana**

Recent Developments in the Electrical Field, by A. D. Atewart, Westinghouse Elec. & Mfg. Co. Discussion. Feb. 18. Att. 43.

Dean H. V. Carpenter, State Col. of Wash., vice-pres. A.I.E.E., gave a report of the winter convention held in New York. Discussion. Feb. 25. Att. 30.

**New York**

Marine Engineering and the American Merchant Marine, by Arthur M. Tode, pres., Propeller Clubs of the U.S. (Transportation group.) Feb. 10. Att. 275.

Characteristics and Protection Requirements of the Low-Voltage A.C. Network, by C. W. Pickells, N. Y., and Queens Elec. Lt. & Pwr. Co., A. Pinto, Otis Elevator Co., L. A. Nettleton, Bklyn. Edison Co. (Power Group.) Feb. 18. Att. 250.

The New Music of Electrical Oscillations, by Benjamin Miessner, Capt. Richard Ranger, and Prof. Leon Theremin. Feb. 26. Att. 875.

Recent Investigations of New York City Smoke, by E. E. Free, N. Y. Univ. March 8. Att. 75.

**Oklahoma City**

Noise Induction Between Power Transmission and Telephone Circuits, by E. B. Jennings, Southwestern Bell Tel. Co., and C. E. Bathe, Oklahoma Gas & Elec. Co. Demonstrations. Jan. 25. Att. 115.

**Philadelphia**

Electron Tubes in Industry, by E. H. Alexander, Genl. Elec. Co. Demonstrations. Jan. 11. Att. 150.

Ship Stabilization by Electrically Controlled Mechanical Devices, by Nicholas Minorsky, Univ. of Pa. Feb. 8. Att. 180.

**Pittsburgh**

The Westinghouse Section Mercury Arc Rectifier, by A. L. Atherton, J. H. Cox, D. C. West, H. Speight, A. J. Maslin, R. R. Longwell, and J. Slepian. Joint meeting with Engrs. Soc. of Western Pa., Feb. 9. Att. 453.

An Outdoor Mercury Boiler Power Station, by A. R. Smith, Genl. Elec. Co. Dinner. Joint meeting with Engrs. Soc. of Western Pa., March 8. Att. 174.

**Pittsfield**

Men Made Island to Speed Ocean Flying, by E. R. Armstrong, Armstrong Seadrome Corp. Feb. 16. Att. 300.

Famous Women Spies and Their Methods, by Maj. Thomas Coulson. Dinner. March 1. Att. 1,450.

**Portland**

Motion pictures describing cable manufacture and short talks on telephone transmission. Feb. 23. Att. 75.

**St. Louis**

The World of Electrons, by Larry Hawkins, Genl. Elec. Co. Feb. 16. Att. 1,600.

**San Antonio**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Feb. 23. Att. 99.

**San Francisco**

Overseas Radio Telephone Servce of the Bell System, by W. H. Harrison, Am. Tel & Tel. Co. Joint meeting with I.R.E. and Signal Corps Assn. Feb. 12. Att. 450.

**Schenectady**

Vertical Transportation in Buildings, by

Bassett Jones, Meyer, Strong, and Jones. Joint meeting with A.S.M.E. Jan. 21. Att. 125.

Air Conditioning in Buildings, by A. R. Stevenson, Gen. Elec. Co. Joint meeting with A.S.M.E. Sec. Feb. 4. Att. 130.

The Great Ice Age in North America, by K. F. Mather, Harvard Univ. Joint meeting with A.S.M.E. Sec. Feb. 18. Att. 425.

**Seattle**

Segregation of Hydroelectric Power Costs, by W. S. McCrea, Jr.; Generator Voltage Regulators, by K. L. Howe; Reflected Voltage Waves in Single Phase Induction Motors, by D. C. Moore; Residential Underground Distribution System, by Wallace Quistorff. W. S. McCrea awarded prize of $25 for presentation of best paper. Jan. 19. Att. 75.

**Sharon**

Modern Marvels, by C. K. Lee, Westinghouse Elec. & Mfg. Co. Feb. 16. Att. 135.

**Spokane**

Institute Affairs and Report on the Winter Convention, by Dean H. V. Carpenter, State Col. of Wash., vice-pres., A.I.E.E. Feb. 26. Att. 21.

**Toledo**

Executive committee meeting. Feb. 9. Att. 9.

Protective Relays, by J. H. Hunt, Toledo Edison Co.; Modern Circuit Interrupters, by J. Slepian, Westinghouse Elec. & Mfg. Co. Demonstrations. Discussion. Feb. 19. Att. 80.

**Toronto**

Non-Resonating Transformers, by K. K. Palueff, Genl. Elec. Co. Demonstrations. Feb. 11. Att. 114.

Automatic Frequency Control, by J. B. McClure, Genl. Elec. Co. Joint meeting with Niagara Frontier Sec. and Engg. Inst. of Canada. Feb. 19. Att. 151.

Some Physical Characteristics of Speech and Music, by Harvey Fletcher, Bell Tel. Labs., Inc. Demonstrations. Feb. 26. Att. 350.

**Urbana**

Modern High Power Transmission Antenna, by Prof. H. A. Brown, Univ. of Ill. March 2. Att. 35.

**Utah**

What Men See With, by A. S. Bennion, Utah Pwr. & Lt. Co. Dinner. Feb. 8. Att. 70.

**Washington**

Some Thoughts on Waves, by O. B. Blackwell, Am. Tel & Tel. Co. Dinner. Feb. 9. Att. 130.

## Future Section Meetings

**Akron**

April 12—The Electrical Industry and Some Problems of the Institute, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Movies.

May 10—Annual banquet and ladies' night. Human Engineering, by Dean Fred E. Ayer, Univ. of Akron. Movies.

**Baltimore**

April 15—Subject to be announced. Speakers from Western Electric Co.

May 20—Speaker: Dr. W. B. Kouwenhoven, Johns Hopkins Univ., vice-pres. A.I.E.E.

**Cleveland**

April 21—Electric Refrigeration and Domestic Air Conditioning, by W. M. Timmerman, Genl. Elec. Co.

May 19—Subject and speaker to be announced.

**Dallas**

April 11—The Coordination of Line and Station Design for Lightning Surge Conditions, by A. O. Austin, Ohio Brass Co.

**Detroit-Ann Arbor**

April 19—Commercial Metering of Electric Energy, by A. S. Albright, Detroit Edison Co.

May 17—House of Magic, by Oliver Ajer, Genl. Elec. Co.

**Louisville**

April 15—Inspection trip to Bowman Field Airport. Fundamentals of Plane Construction and Flight, by A. W. Lee, Louisville Gas & Elec. Co.

May 13—Dial Telephone Equipment in Louisville. Speaker from Southern Bell Tel. & Tel. Co.

**New York**

April 15—Final meeting of power group; general subject: regulation of power flow between interconnected systems. General Problems of Interconnection, H. L. Melvin, Electric Bond and Share Company; Automatic Control of Frequency and Load, J. B. McClure, Genl. Elec. Co. Election of power group officers. Meeting to be held in Engineering Societies Building at 7:30 p.m.

**Pittsburgh**

April 12—Television. Demonstrations. Joint meeting with I.R.E.

May 10—Annual banquet and ladies' night.

**Seattle**

April 19—Joint meeting with Student Branch at Univ. of Wash.

May 17—Address by L. Sapovi, Hooker Electro-Chemical Co.

**Spokane**

April 22—New Developments in Oil Circuit Breakers, by J. F. Spease, Genl. Elec. Co.

May 27—Annual dinner meeting. History of the Electrical Development of the Inland Empire, by John B. Fisken. Election of officers.

**Toledo**

April 15—Problems in the Design of Large Turbo-Alternators, by S. H. Mortensen, Allis-Chalmers Co.; Application of Electricity in Industry, by R. E. Paxton, Toledo Edison Co.

**Vancouver**

April 4—Switchgear, by W. D. Robertson, Canadian Genl. Elec. Co., Ltd.

May 2—Open.

May 21—Annual outing to the Baker River Plant of the Puget Sound Pwr. & Lt. Co.

## Past Branch Meetings

**University of Akron**

Biography of Alexander Graham Bell, by R. I. Felver, student; Baffle Boards and Their Relation to Modern Loudspeakers, by Sol. Leibowitz, student. Demonstrations. Feb. 24. Att. 9.

**Alabama Polytechnic Institute**

Electrification of the Norfolk and Western Railway, by F. N. Williams, student; Telephone Systems, by D. P. Johnson, student. Feb. 18. Att. 10.

Manufacture of Cast Iron Pipe by the Mono-Cast Centrifugal Process, by S. D. Moxley, Am. Cast Iron Pipe Co. Joint meeting with A.S.M.E. Feb. 2. Att. 45.

**University of Arkansas**

Non Sine Waves, by H. G. Thomasson, student; Vectors, by E. E. Ray, student; Harmonic Analizers, by J. G. Lewis, student. Feb. 3. Att. 35.

Electric Shovels, by Robert Vining, student; Brushes, by E. E. Boreland, student; Automatic Stops for Elevators, by F. L. McDonald, student. Feb. 15. Att. 30.

**Armour Institute of Technology**

Building Networks, by E. E. Chilberg, Genl. Elec. Co. Feb. 19. Att. 30.

**University of British Columbia**

Automatic Telephony, by J. W. McRae, student. Discussion of transmission systems. Feb. 9. Att. 14.

The C.G.E. Test Course, by S. D. Scott, student; The Automatic Switchboard Installed for the Powell River Pulp and Paper Co., by H. E. Woodland, student. Film—"The Transportation Problem." Feb. 23. Att. 19.

Film—"Electrification of the Mexicana Railway." Feb. 24. Att. 100.

**Brooklyn Polytechnic Institute**

The Pianoforte or Engineering Applied to the Art of Music, by Wm. B. White, Am. Steel & Wire Co. Demonstrations. Refreshments. Jan. 14. Att. 200.

**Bucknell University**

Lighting and Its Relation to Industries, by George Heinish, student. Feb. 11. Att. 12.

**University of California**

The Development and Application of Vacuum Tubes, by A. W. Copley, Westinghouse Elec. & Mfg. Co., vice-pres. A.I.E.E. Banquet. Feb. 19. Att. 46.

Engineering Observations on a Recent Trip East, by W. C. Smith, Genl. Elec. Co. Feb. 24. Att. 35.

**Case School of Applied Science**

The Research Attitude, by Prof. T. D. Owens; Safety Devices on Street Cars, by J. C. Elder, student; X-Ray Protective Devices, by W. J. Cherney, student. Feb. 17. Att. 51.

W. J. Cherney elected chairman. March 4. Att. 43.

**Catholic University of America**

Electricity and the Telephone, by Mr. Gioffre, Chesapeake & Potomac Tel. Co. Refreshments. Feb. 24. Att. 3.

**University of Cincinnati**

Elevator Motors and Control, by A. J. Liebenberg, Warner Elev. Co. Feb. 17. Att. 40.

**Clemson Agricultural College**

Photoelectric Tubes, by Prof. F. T. Tingley; The Present Practises in Insulated Power Cables, by W. G. Wallenberg, student. March 3. Att. 20.

**University of Colorado**

Films—"Speeding up Our Deep Sea Cables" and "Pictures by Wire." Refreshments. Feb. 10. Att. 55.

New Ideas for High Voltage Circuit Breakers, by C. A. Church and N. R. Damon. Slides. Feb. 24. Att. 30.

**Cooper Union**

Engineering Aspects of the Soviet Five Year Plan, by W. N. Polakov. Feb. 4. Att. 70.

**University of Denver**

Films—"Mazda Lamps," "Electric Ships," "Liquid Air," and "A Visit to the General Electric Factory With Earl Carroll." Feb. 18. Att. 84.

**University of Detroit**

Construction and Application of Storage Batteries, by W. C. Leingang, Elec. Stor. Bat. Co. Film—"The Electric Ship." March 2. Att. 45.

**Duke University**

Mercury Arc Rectifiers, by Mr. Creekmore, student. Discussion. Feb. 11. Att. 13.

Illumination and Neon Tubes, by Mr. Garrett, student; Short Wave Receiving Circuits, by Mr. Flack, student. Feb. 25. Att. 13.

**University of Florida**

Amateur Radio, by G. W. Haug, student; The Kennelly-Heaviside Layer and Methods for Determining Its Height, by D. G. Beck. March 7. Att. 25.

**Georgia School of Technology**

Films—"Automatic Arc Welding" and "Busy Body." Feb. 16. Att. 60.

**University of Illinois**

Discussion of plans for the elec. engg. show. Feb. 17. Att. 100.

**Iowa State College**

Film—"The Life of Edison." Feb. 10. Att. 50.

**University of Iowa**

Films—"General Electrical Icing Unit." Election of officers as follows: H. A. Peterson, chmn.; L. E. Travis, vice-chmn.; J. F. Kapinos, secy-treas. Feb. 3. Att. 44.

Discussion. Feb. 10. Att. 24.

Electrical Relays, by M. J. Larsen, student. Feb. 17. Att. 30.

New Radio Air Cell a Battery, by L. F. Grizel, student; The Growth of the University Radio Station, by R. E. Griffin, student; Electricity in the Moffat Tunnel, by D. G. Fritz, student; Television, by E. C. Dunn, student. Feb. 24. Att. 38.

### Kansas State College

Election of officers. Feb. 4.

Talk by G. W. Wood, Frigidaire Co. Feb. 18. (Afternoon meeting.)

Russia, by J. C. Bradley. Feb. 18. (Evening meeting.)

### University of Kansas

Cooperative Education, by Prof. D. C. Jackson, Jr., counselor. Feb. 18. Att. 36.

The Making of a Life, by R. A. Schwegler, dean, school of education. Films—"Far Speaking" and "Voices Across the Sea." March 3. Att. 54.

### Lafayette College

Welding, by A. S. Cumberland, Ingersoll-Rand Co. Illus. Joint meeting with A.S.M.E. and A.S.C.E. branches. Feb. 26. Att. 50.

### Louisiana State Univeristy

The Wyman Dam Hydroelectric Project, by E. E. Frenzel, student. Feb. 18. Att. 19.

### University of Louisville

Advantages of Governmental Control, by J. Groves, student; Advantages of Private Ownership, by J. Morris, student. Feb. 12. Att. 11.

### University of Maine

Planning a Power System, by H. W. Coffin, Bangor Hydroelec. Co. Feb. 25. Att. 23.

### Marquette University

Magnetic Testing, by Prof J. F. H. Douglas, assisted by Messrs. Trimborn, Dernbach, Hallbach, and Van Peterson, students. Feb. 4. Att. 20.

### Massachusetts Institute of Technology

Inspection trip through the L Street generating station of the Edison Elec. Ill. Co. Feb. 19. Att. 15.

The Thyratron Tube, by H. M. Wagner, student. Dinner. Feb. 25. Att. 65.

### Michigan College of Mining and Technology

Industrial Applications of Vacuum Tubes, by R. E. Welton, Gen. Elec. Co. Films "Automatic Substation for Mining and Industrial Service" and "Big Deeds." Feb. 11. Att. 36.

### Michigan State College

The Development of the Vacuum Tube, by W. A. Stelzer, student. Feb. 23. Att. 11.

Methods of Fixing Light and Power Rates, by Mr. Carolyn, Consumers Pwr. Co. March 8. Att. 14.

### School of Engineering of Milwaukee

Organization, Purpose, Duties, and Operation of the Milwaukee Fire Department, by Mr. Lippold, asst. fire cf. Feb. 10. Att. 46.

### University of Minnesota

Inspection trip through the Elec. Mchy. Mfg. Co. Feb. 18. Att. 65.

### University of Missouri

Ultra High Frequency Oscillations, by C. Thorne and L. Smarr, students; Television, by H. Leibovich and L. Buell, students. Feb. 17. Att. 18.

Adventures in Science, by L. A. Hawkins, Genl. Elec. Co. Joint meeting with Sigma Xi. Feb. 27. Att. 263.

### Montana State College

The Swope Plan, by A. J. Hill, student; A Modern Laundry, by C. G. Anderson, student; Electric Arc Welding in Mines, by E. Hughes, student; Development of Transformers, by R. MacDonald; The Origin of the Electrical Science, by Wm. H. Scheele. Jan. 28. Att. 103.

### University of Nebraska

Film—"Power Transformers." Feb. 17. Att. 22.

Demonstration of thyratron tubes by L. W. Cook and P. Ehrenhard, students. March 2. Att. 34.

### Newark College of Engineering

Photoelectric Cells, by J. Wier, student; Application of Photoelectric Cells, by W. Amon, student; Thyratron Inverter, by W. R. McLaughlin, student. Feb. 29. Att. 22.

### University of New Hampshire

Film—"Something About Switchboards." Jan. 9. Att. 28.

A New Warning Beacon Which Utilizes the Vacuum Tube, by A. Philbrick, student; Convict Labor in Highway Construction, by H. W. Feindel, student. Jan. 16. Att. 27.

The Solution of Unbalanced Faults on Transmission Lines by the Method of Symmetrical Coordinates, by H. R. Stewart, Westinghouse Elec. & Mfg. Co. Jan. 20. Att. 78.

Discussion. Feb. 6. Att. 24.

The Future Engineer, by O. K. Reed, student; The Electron Tube in Industry, by H. W. Hunt, student. Feb. 13. Att. 21.

Discussion of plans for spring inspection trip. Feb. 20. Att. 22.

Discussion. Feb. 27. Att. 26.

Predetermined Counter and Its Uses, by J. Prentice, student; Diesel Electric Drives Used on Tramp Steamers, by R. D. Ives, student. March 5. Att. 21.

### University of New Mexico

Discussion of plans for engineers' day. Feb. 17. Att 10.

Engineering Achievements of the General Electric Co. During 1931, by Martin Zirhut, student. Feb. 25. Att. 17.

### College of the City of New York

Discussion. Feb. 18. Att. 18.

The Tools of Modern Warfare, by Maj. Carl de Zafra, U.S. Army. Feb. 25. Att. 44.

Some Recent Developments in Electrical Communication, by R. D. Parker, Am. Tel. & Tel. Co. Demonstrated. March 3. Att. 40.

### New York University

Quasi Optical Waves, by E. H. Osterland, student; Labor Unions, by W. Rubsamen, student. Feb. 16. Att. 12.

Amateur Radio Station Equipment, by J. Mantone, student; Measurement of the Moisture Content of Wood by Electrical Methods, by A. W. Lebert, student. Feb. 23. Att. 13.

The Present Patent Situation, by L. C. Dinnar, student; Quartz Crystal Oscillators, by H. C. Fleming, student. March 1. Att. 13.

The Development of the Use of Electricity at Sea, by J. P. Munroe, student; The Inductive Compensating Generator, by C. J. Dunn, student. March 8. Att. 13.

### North Carolina State College

Neon Tubes, by K. L. Ponzer, student; Late Electrical Developments, by C. M. Smith, student; Amateur Radio Transmission and Reception, by D. A. Worsley, student; Electricity in Syria, by Joseph Salem, student. Jan. 26. Att. 31.

Film—"General Electric Enameling Furnace." Feb. 9. Att. 21.

### North Dakota State College

Recent Developments in Modern Illumination, by O. P. Cleaver, Westinghouse Elec. & Mfg. Co. Feb. 5. Att. 93.

Impressions of Engineering, by Foster Buck. Film "The Story of the Glass Bottle." Joint meeting with A.S.M.E. and A.S.C.E. branches. Feb. 18. Att. 66.

### University of North Dakota

Engineering Developments in 1931, by L. A. Myrand, Westinghouse Elec. & Mfg. Co. Film—"Dynamic America." Feb. 17. Att. 32.

Television, by O. A. Bondeled, North Western Bell Tel. Co. March 2. Att. 28.

### Northeastern University

The Cathode Ray Oscillograph, by H. W. Samson, Genl. Radio Co. Demonstrations. Feb. 17. Att. 82.

### University of Notre Dame

Motor Control, by C. J. Maloney, Cutler Hammer Mfg. Co. Demonstrations. Incidents in the Development of Electric Traction, by P. McCaffrey, student. John Scanlan, student, presented the new reviews. Feb. 15. Att. 77.

Manufacture of A Radio Tube, by W. S. Brian, Grigsby-Grunow Co.; Development of the Incandescent Lamp, by C. Roberts, student; Sound on Filament, by L. Simmons, student; Engineering Culture, by H. E. Ball, student. John Scanlan, student, presented the usual current review. Feb. 29. Att. 71.

### Ohio Northern University

A.C. Welding, Conception of the Electron Theory, and Methods of Locating Grounds on Power Lines, by O. R. Jacobs, student. Jan. 14. Att. 19.

Home Lighting, by L. Berger, student. Demonstrations. Jan. 28. Att. 9.

### Ohio University

Film—"From Mine to Consumer." H. B. McCrone, Am. Brass Co., explained the film. Feb. 17. Att. 55.

Edison Three Wire Transmission Lines, by R. H. Lloyd, student. March 9. Att. 13.

### Oregon State College

Life of Edison, by B. Blazen, student. Short Wave Radio Transmission to Hawaii, by R. W. Deardork, Pac. Tel. & Tel Co. Demonstrations. Feb. 11. Att. 57.

### Pennsylvania State College

The Recent Tube Developments of Interest to Industry, by H. L. Saxton. Feb. 19. Att. 75.

### University of Pittsburgh

Electrification of Railroads, by C. E. Coleman, student; Life of Faraday, by W. Piercy, student. Jan. 14. Att. 128.

Operation of Automatic Train Signaling, by H. E. Kallenburger, Union Switch and Signal Co. Demonstrations. Jan. 19. Att. 87.

Industrial Application of Vacuum Tubes, by R. Hansen, student. Feb. 4. Att. 127.

Code System of Continuous Train Control, by O. L. Zimmerman, student; Methods of Rolling Steel Plates, by M. Zofchak, student. Feb. 11. Att. 120.

Photoelectric Cells, by Wm. Dambart, student. Feb. 18. Att. 126.

Mercury Arc Rectifiers, by Mr. Atherton, Westinghouse Elec. & Mfg. Co. Feb. 25. Att. 126.

### Pratt Institute

Film—"Manufacture of Electric Cables." Feb. 4. Att. 25.

Electricity and the Pipe Organ, by D. Enslee, student. Feb. 17. Att. 20.

### Princeton University

Film—"Electrical Measuring Instruments." Feb. 11. Att. 8.

### Purdue Univ.

Einstein's Theory, by R. J. Kryter, Prest-O-Lite Stor. Bat. Co. Feb. 16. Att. 508.

### Rhode Island State College

Television, by Messrs. Daly and Downes, students. Feb. 25. Att. 12.

### Rice Institute

Election of Officers as follows: E. A. Turner, Jr. chairman; G. R. Adams, vice-chairman; J. E. Reed, secy.; R. C. Bearmann, treas. Feb. 17. Att. 11.

### Rose Polytechnic Institute

History and Manufacture of Cables, by F. E. Calvert, Gen. Elec. Co. March 3. Att. 36.

### Rutgers University

The Twin Function of Engineering, by J. Rudnitsky, student. Feb. 16. Att. 17.

Sweep Circuits of Cathode Ray Oscilloscope, by B. Schmurak, student. Feb. 23. Att. 20.

### University of South Carolina

Television Scanning by Means of Cathode Ray Tubes, by R. M. Warren, Jr., student; Unloading of Grain Cars, by J. T. Lyman, student; Dial Type Thermotel, by E. C. Willis, student. March 10. Att. 55.

### South Dakota State School of Mines

Combustion, by Chuck Laws, Montana-Dakota Pwr. Co. Feb. 25. Att. 28.

### University of South Dakota

Film—"The Single Ridge." Feb. 16. Att. 35

### University of Southern California

Discussion. Feb. 3. Att. 15.

Discussion and moving pictures. Feb. 10. Att. 31.

### Southern Methodist University

Underground Distribution Network System of Dallas Power & Light Co., by M. M. Lehmberg, student. Feb. 16. Att. 12.

Luncheon. Feb. 24. Att. 11.

### Stanford University

Radio Broadcasting Station at Sanford and Its Equipment, by P. F. Byrne, student; High Voltage Transmission, by Prof. J. S. Carroll, counselor. Jan. 14. Att. 28.

Inspection trip through the studios of the Natl. Broadcasting Co., Inc. Jan. 30. Att. 40.

Television, by A. H. Brolley, Television Labs. Feb. 4. Att. 68.

Design of the Portable Motor Generator Set Which Was Used by the Byrd Antarctic Expedition, by Mr. Heintz, Heintz and Kaufman. Joint meeting with A.S.M.E. Branch. Feb. 10. Att. 42.

### Stevens Institute of Technology

Personnel Work in the New York Edison Co., by Prof. F. C. Stockwell, counselor. Feb. 5. Att. 38.

The Setting of Clocks by Radio, by Prof. H. C. Roters. Feb. 16. Att. 26.

### Syracuse University

The Piezo Electric Effect and Its Utilization, by J. L. Schmieder, Jr., student; History of the Telephone, by Wm. Bangs, student. Feb. 12. Att. 21.

Control Frequency Broadcast, by L. G. Curry, student; Electrolysis of Cast Iron Pipe, by H. Coswell, student. Feb. 19. Att. 21.

The Earth as a Current Conductor, by F. DeBoalt, student. Feb. 26. Att. 21.

### A. & M. College of Texas

Some Developments by G.E. in 1931, by W. Clayton, Gen. Elec. Co. Illustrations. Various G.E. Products, by Mr. Alen, Genl. Elec. Co. Feb. 11. Att. 94.

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Feb. 25. Att. 800.

### Texas Technological College

Life of Thomas A. Edison, by W. Nott, student. Slides. Feb. 11. Att. 14.

### University of Texas

Harmonic Analysis of Distorted Wave Form, by Dr. S. L. Brown. Feb. 11. Att. 12.

### University of Utah

The History of Amateur Radio, by L. K. Irvine, student. Discussion. Jan. 28. Att. 37.

Debate: Resolved: That the Engineer Has Caused the Depression. Affirmative—D. Ashby, R. C. Hansen, students. Negative—S. Ramo, R. Kirkman, students. Negative side won. Feb. 25. Att. 36.

### University of Vermont

The Effect of Electrode Shape on High Voltage Stresses in Insulators, by Mr. Whitman. Illus. Feb. 15. Att. 19.

### Virginia Polytechnic Institute

Light Relays and Light Source Units, by R. W. McCorkle, student; Power Auxiliaries, by H. E. Naylor, student; Active and Inactive Duties of the Advanced R.O.T.C. Student, by M. H. Mills, student; Electric Heating and Wood Block Floor Construction, by C. K. Luck, student. Feb. 11. Att. 47.

Method of Weighing Small Particles, by W. C. McCall, student; Oil Filled Cables, by W. L. Outten, student; The Prerequisites of an Electrical Engineer, by G. R. Snyder, student; High Speed Submarine Cables, by A. I. Osborne, student; New Power Transformers, by T. E. Gilhooley, student; Electrical Operation of Dredges, by A. L. Pond, student. Feb. 18. Att. 54.

Use of Natural Has for Generating Electrical Energy, by J. H. Pharis, student; Three Power Locomotives, by J. E. Hamm, student; Electro-Plating, by A. M. Potts, student; The Economic Phase of Electrified Railroads, by W. C. Cottrell, student. Feb. 25. Att. 54.

The Oscillograph, by H. A. Frazier, student; The Life of Samuel Morse, by R. E. Philbeck, student; Load Ratio Control for Transformers, by C. L. Tune, student; Development of Transcontinental Radio Telephones, by D. H. Smith, student; Dial System Automatic Telephones, by E. L. Rowell, student. March 3. Att. 50.

### University of Virginia

The Qualifications of an Electrical Engineer, by R. B. Jones, student; Traffic Operated Traffic Signal, by B. G. Switzer, student; Believe It or Not—Pertaining to Electrical Engineering, by T. J. LoCascio, student. Feb. 12. Att. 26.

### Washington State College

Election of officers as follows: Philip Nalder, pres.; T. Torkelson, vice-pres.; Gus H. Bliesner, secy.; H. Brittenham, treas. Jan. 29. Att. 22.

Power Plant Achievements for 1931, by R. Uhlig, student; Electrical Instruments, by Prof. O. E. Osburn, counselor. Feb. 12. Att. 26.

### University of Washington

Televox, by W. Blashfield, student. Feb. 4. Att. 11.

Electrical Reflections in Induction Motors, by D. J. Moore, student. Feb. 11. Att. 15.

The Public Utilities Place in the Electrical Industry, by H. A. Gardner, Puget Sound Pwr. & Lt. Co. Feb. 18. Att. 17.

Film—"Conowingo." Feb. 25. Att. 72.

Diablo-Seattle Transmission Line, by C. M. Lubcke, Engg. Dept., City of Seattle. March 5. Att. 27.

### West Virginia University

History of Rate Making, by H. Locker; Diesel Engines as Peak Load Units, by L. Palmer; An Interview of Dr. H. C. Rentschler, by P. B. Spangler; Engineering Features of Three Power Locomotives, by E. D. Harris; Remote Reading of Watt Hour Meters, by L. P. Kirwin; Vacuum Tube History, by K. H. DeMoss; The Dynamic Radio Microphone, by P. M. Vannoy; all students. Feb. 9. Att. 31.

Power for an Arctic Elevator, by J. L. Simpson; Automatic Combustion Control, by R. H. Colborn; Measuring High Radio Frequencies, by N. I. Hall; Shocks Due to Electricity, by L. H. Winger; Communication in the Waldorf Astoria, by M. Stewart; Photoelectric Recorder, by W. C. McMillian; Foreign Jobs, by W. C. Sandy; all students. Feb. 16. Att. 31.

Development of the Chinese Electrical Industry, by M. Sprigg; Remote Reading of Watt Hour Meters; by D. C. Kennedy; Electric Heating in Wood Block Floor Construction, by J. E. Wallace; Corona Versus Conductor Surface, by F. O. Brown; Transoceanic Radio Telephone Service, by C. J. McCormick; all students. Feb. 23. Att. 29.

Gas Electric Railway Car, by R. H. Colburn; All Wave Radio Receiver, by N. I. Hall; Electrical Units and Their Application, by C. J. DeLancy; Electricity on the Airship Akron, by L. H. Winger; Reducing Noises From Power Transformers, by W. C. Sandy; all students. March 1. Att. 29.

### University of Wisconsin

The Private Life of Michael Faraday, by M. L. Dack, student; Michael Faraday's Experiment, by P. E. Patterson, student; Electrical Researches of Faraday, by J. K. Affanasiey, student. Dec. 10. Att. 47.

Dancing Conductors, by W. A. Kuehlthau, student. Moving pictures. Jan. 19. Att. 64.

Electrical Engineering Only? by Charles Moore, Bell Tel. Labs., Inc. Feb. 11. Att. 76.

### University of Wyoming

Electron Theory, by Dr. P. F. Hammond, head, physics dept. Joint meeting with A.S.M.E. Branch. Feb. 23. Att. 17.

## Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Berry, Wayne J., c/o Genl. Elec. Co., Schenectady, N. Y.
Bugg, Vernon, 736 Transportation Bldg., Washington, D. C.
Combs, Clinton R., 13564 Northlawn Ave., Detroit, Mich.
Fay, John L., Genl. Del., Philadelphia, Pa.
King, Milton E., 1521 Laketon Rd., Wilkinsburg, Pa.
Master, J. J., 36–7 Canning St., Calcutta, India.
Miyamoto, Tatsuo C., 1330—4th St., Sacramento, Calif.
Palit, Hari-Charan, 151 Ganesh Mohal, Benares City, India.
Rogge, C. A., Consumers Pwr. Bldg., Jackson, Mich.
Thomas, Earl Mead, Intl. Genl. Elec. Co., Schenectady, N. Y.
Titland, Trygve T., 1019 Stanton Ave., Elizabeth, N. J.
Van Der Dussen, John, 114 Gotham Ave., Gerrittsen Beach. B'klyn, N. Y.

# Employment Notes

## Of the Engineering Societies Employment Service

## Men Available

### Construction

DISTRIBUTION ENGR., 29, married, tech. grad. 8 yr. experience in utility field as supt., mgr., engr. foreman, and lineman. One year constructing municipal power and ice plant. Eighteen months elec. installation in large industrial establishment. Available immediately. Location, immaterial. D-442.

ASSOC. E.E., 25, 8 yr. practical experience in elec. construction work on new bldgs., power plants, and alterations. Familiar with all branches of elec. contracting including field engg. and inspections. Has had complete charge of elec. design and construction outside of New York City. Excellent references. D-502.

ELEC. CONSTRUCTION ENGR., E.E. Grad., 1928, 28, married. 3 1/2 yr. experience with large elec. contractor in estimating, design, control work and field supervision. Also 3 yr. experience in accounting, cost and stenographic work. Excellent references. Available immediately. D-46.

E.E., 33, with 10 yr. practical experience in elec. construction work on new bldgs. Familiar with all branches of elec. contracting including estimating, field engg. and purchasing. Have been in complete charge of elec. work in various large building projects in New York City. A-850.

### Design and Development

E.E. GRAD., 35, single, mfg., maintenance, operation, designing experience. Inventions. Foreign languages. Desires responsible position with mfg. industry. (Development or production. Transformers; elec. locomotives; control, etc.) Location, immaterial; eastern preferred. D-452.

FORMER CORNELL INSTRUCTOR IN MACHINE DESIGN for 4 years, Allis-Chalmers designer and checker 5 years, M.E. and E.E. deg., shop apprenticeship and miscellaneous experience, 32, single. Desires teaching or engg. opportunity. Salary open. D-122.

DESIGN ENGR., col. grad., 38, married, citizen; 6 yr. elec. plant construction, wide experience all features design of pwr. and substations and industrial light and pwr., 3 yr. field experience as tester and supervisor. Desires position with utility, engg., or construction firm. Available immediately location, immaterial. D-482.

ELEC.-MECH. ENGR. with metallurgical knowledge. Col. grad. with post-graduate study, 30, married. Westinghouse design training. 6 yr. experience design elec. circuits and mechanical details of control apparatus, specialized in elevator equipment. Interested in alloy welding research. Location, immaterial. Available on short notice. C-9638.

E.E., GRAD., M.I.T. 1925, 30, married, 6 yr. utility design and engg. Capable complete elec. design steam, hydro station, high-, low-voltage

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco

205 West Wacker Drive
Chicago

31 West 39th St.
New York

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New york office, with an extra two-cent stamp enclosed for forwarding.

substations. Short circuit, relay studies large networks. Knows industrial control design. Available at once. Location not important. C-6366-322-C-5-San Francisco.

DESIGN ENGINEER, E.E. GRAD., 10 yr. power plant, d-c. rectifier substations, industrial and illumination experience. Expert draftsman, mathematician, knowledge of vacuum tubes, photocells, and their application in industry. Contributed many articles in engg. journals on original developments. East preferred, available immediately. B-7332.

E.E. GRAD., 45, married, G. E. Test and design experience; over 15 years' experience with larger companies in design and manufacture of transformers for special requirements, as well as standard lines. Desires position with utility or mfr. where experience will be valuable. Available on short notice. C-8806.

E.E. GRAD., 1930, 23, single, cooperative experience. 3 yr. with utility in central station design and construction. 1 yr. designing automatic pumping installations, floodlighting and general lighting, carrying full responsibility for all designs. Available immediately. Location, East preferred. D-561.

E. E. GRAD., 27, married. 5 yr. experience elec. and mech. design motors, fractional hp. to 500 hp. a-c. and d-c. 1 yr. experience substation and transmission line design. Grad. radio school. Thoroughly familiar with mfg. problems. Capable of assuming responsibilities of design. Nationally known references. Location, immaterial. Available immediately. D-565.

E.E. GRAD., 29, single, 2 yr. additional study in accounting. 5 yr. experience elec. and mech. design and development of fans and small motors with leading mfr. Desires position with mfg., utility or engg. concern or teaching elec., mech. drawing. Location, East. D-580.

ELEC. AND MECH. DESIGN ENGR., 48, E.E. grad., LL.B. and attorney at law. Power houses, substations and gen. steel mill engg. with special training in legal work connected with industrial concerns. Available at once. Preferred location, Ohio or Pittsburgh district. D-589.

E.E., 38, single. 13 yr. experience in design of mchy., apparatus, substations, hydro and steam pwr. plants with well known concerns, $6\frac{1}{2}$ yr. in last position. Desires connection with concern where ability and adaptability will lead to advancement. C-347.

### Executives

CONSTRUCTION: ASSOC. E. E., 32, 16 yr. practical experience, elec. construction on new bldg. and repair work, familiar with all branches of elec. contract work including estimating, engg., purchasing, and inspection. 10 yr. in charge of elec. contract dept. for an elec. contractor. Location, immaterial. Available immediately. Salary open. D-478.

E.E. GRAD., married, 23 yr. experience in engg. and exec. capacities in industrial plants covering design, layout, contracting and purchasing of mfg. equip. and power plants including mech., elec., refrigerating, air-conditioning, and new processes for soap, drug, candy food products, and textile plants. D-488.

E.E., B.S. M.S. deg. 45, experienced in utility and industrial applications. Permanent position desired. D-498.

E.E. GRAD., 35, married. 5 yr. experience in system operating planning with utility, also sales, construction and some elec. maintenance experience. Past 2 yr. as design engr. with large elec. mfg. company. Can become valuable in any position. Exec. desired. Available now. Location, immaterial. B-7827.

GRAD. E.E., professional engr. license N. Y. State, 10 yr. experience elec. pwr. plants, substations, distribution, lighting, industrial installations, and specifications, wishes connection with firm which can use man possessing chief characteristics as: Speed, thoroughness, willingness to work hard, accuracy, energy. Part or full time. Excellent references. D-454.

GRAD. E.E., 32, single. 9 yr. design and construction of pwr. transmission lines, substations and distribution networks as engg. inspector, purchasing, expeditor, preparing estimates and writing specifications. Excellent references. Desires connection with holding or operating company, contractor or mfr. Available immediately. Location, immaterial. C-3564.

E.E. GRAD., 4 yr. experience, drafting, design, construction, and engg. of modern hydro and steam pwr. plants, substations and ry. electrification. $5\frac{1}{2}$ yr. with leading mfg. concern in engg. of automatic and manual switchgear equipment. Foreign languages. Desires position, utility, engg., mfg. or ry. concern. Location, immaterial. B-7938.

E.E. GRAD., 26, married. 5 yr. with engg. dept. of holding company until merger, full experience in design, supervision and construction of substations and transmission lines. One year G. E. Test. Licensed electrician. Knowledge of radio testing and servicing equip. Available immediately. D-568.

E.E., 36, family. 15 yr. with engg. organizations: reports, designs, layouts, construction, performance tests, contracts and purchase, large industrial plants, utility pwr. plants, substations and network distribution systems; executive experience. Registered in Pa. Unemployed. Prefers consulting, maintenance, design, sales work in East, but will consider any location. C-2570.

E.E., Univ. of Va., 1924, single, desires place requiring hard-working tech. engr. of genl. experience in engg. dept. of utilities and cable mfr. on transmission circuits, elec. measurement and equip., inductive coordination, and insulation and cables in particular. Will accept temporary position in U.S. to prove ability. C-2282.

E.E. GRAD., 37, married. 4 yr. design on motors, control, steam turbines and engines. 8 yr. production, development, experimental work on centrifugal pumps and air compressors, elec. control equip. B-6926.

E.E. AND ESTIMATOR, 26 yr. experience, estimating, supervising and engg. for contractors, engg. for architects, etc., would like position with elec. contractor. Best of references. East or South preferred. C-8460.

E.E. GRAD., 14 yr. experience utilities in valuation work, rate investigations, engg. pwr. plants, substations, transmission lines, including estimates, specifications, design. Experience covers short-circuit studies, stability analysis, investigations of systems for load conditions. Desires position holding or operating company, or engg. firm. Available immediately. C-9570.

E.E. GRAD., experienced in elec. pwr. field desires position with pwr. company or mfg. firm. Able to supervise drafting, construction, and maintenance. B-1923.

CHIEF E.E., 36, E.E. grad. Extensive experience charge of design, construction, operation, maintenance plant, substations, transmission, trolley, telephone lines; maintenance elec. rolling stock, steam train lighting, elec. drive, lighting equip. factories, shops, offices, etc. Record of rapid advancement. Good organized. Successful handling Latin-American labor. Speaks Spanish. School grounding in French. C-9557.

E.E., experienced in load forecasting for economical planning for future growth. Established methods and records for systematic handling of estimates on property including 300 communities. Familiar with unit costs, estimates, and budgeting. Also experienced in elec. planning, design, and construction of transmission, substations and distribution. B-2876.

TECH. GRAD., married, 38, with $11\frac{1}{2}$ yr. experience as distribution, field and office engr.; $4\frac{1}{2}$ yr. tests, shop and construction work; desires position in engg. or operating dept. of utility. Location, immaterial. Available immediately. B-9248.

### Instruction

GRAD. E.E., 1929; M.S. deg. 1931, Ohio State Univ. Ph.D. requirements partially completed. Experience in the fields of telephony, acoustics, and ry. signalling. Desires engg. or teaching position. Location, immaterial. D-475.

GRAD.; E.E., M.I.T., 35, married. 6 yr. industrial and teaching experience in E.E. Several years private research and development work on own initiative. Good ability, integrity, and personality. Desires position for life work. Location preferred, Middle West or South. C-2836.

ENGINEER-INSTRUCTOR; B.S., M.A.; 36, married. Desires college teaching connection. Teaching and lecturing experience, 10 yr. research and radio experience. Can teach E.E., radio, and physics. Available in fall or summer. C-1087.

PROF. OF E.E., B.S., and E.E. deg. 41, 6 yr. successful experience teaching practically all branches of E.E., state school. Considerable experience power, telephone work. 1 yr. switchboard engg. dept. Westinghouse. Available school year 1932–33. C-5021.

E.E. GRAD., 33, married. $3\frac{1}{2}$ yr. service engr. on pwr. and industrial apparatus and control. 2 yr. instructor in E.E. at state univ. 2 yr. transformer design and genl. engg. $\frac{1}{2}$ yr. pwr. and substation construction. Desire engg. opportunity or teaching. C-1073.

E.E. PROF., B.S., and E.E., 33, married. $2\frac{1}{2}$ yr. G.E. Co., 5 yr. with utility, 4 yr. teaching, 1 yr. as acting head of dept. Desires change. Location, South or Middle West preferred. C-7152.

ASST. PROF. E.E., leading tech. col. of East, desires position, industrial concern where knowledge and experience gained in 14 yr. teaching fundamental courses in E.E. can be utilized in development, research, construction. M.I.T. graduate, married, 35, perfect health. Interested especially, elec. measurements, measuring instruments. Experienced draftsman, checker. D-581.

### Maintenance and Operation

E.E., GRAD., married, 28; wide experience in industrial plant elec. construction and maintenance; ry. electrification; pwr. plant design, estimating, and supervistory construction experience with elec. contractor; cost analysis. Desires position with future. C-4428.

E.E. GRAD., 1928, 6 yr. hydro and steam plant elec. operation and maintenance, 5 yr. office and cost accounting. Would desire position with utility or mfg. concern in any part of U. S. or foreign. Salary secondary to opportunity. C-7796.

### Junior Engineers

E.E., 28, married. Experienced in capacity of load dispatcher of pwr. Co., having interconnections with other companies. 6 yr. college work, including business training. D-468.

GRAD. E.E. 1931, Rensselaer Poly. Inst., single, 23. Desires position with any reliable engg. firm with opportunity for advancement. Salary immaterial. Wide engg. training. Best of references. Location, Eastern preferred or will consider any location. Available immediately. D-470.

E.E. GRAD., 1929, 26, single. 3 yr. experience in oil burner control equip. $1\frac{1}{2}$ yr. head of experimental test dept. of large mfr. of automatic heat control equip. Location preferred, Middle West. Available at once. D-486.

E.E. GRAD., 1931, single, 22. Experience in drafting and design of switches and pwr. distribution panels. Desires position in utility service and transmission of pwr. Also interested in research in the various branches of physics. Location, immaterial. Available immediately. D-471.

E.E. GRAD., 1929, M.S. 1931, leading univ., 18 months G.E. Test, 23, single. Desires to teach in tech. univ. Prefers Mid-West. C-9320.

E.E. GRAD., 22, 10 months' experience on construction. Desires employment with utility, engg., or mfg. concern. References furnished. Available with short notice. C-9885.

E.E. GRAD., 24. 3 yr. experience in industrial installation and control. Dull experienced with a-c. or d-c. elec. automatic drives and control. Desires position with utility or mfg. concern. Location, immaterial. Available on month's notice. C-8763.

GRAD. E.E., Univ. of North Carolina, 1931, 22, single. Extra study liberal arts and commerce schools. Desires position any engg. field, preferably telephone work. Four summers experience, Ill. Bell Telephone Co., installation and maintenance. Salary immaterial at start. Any location, foreign or U.S. Available immediately. D-527.

E.E. GRAD., 1931, 25, single, cooperative college. Limited experience with battery mfg. concern. Desires position with a future. Salary and location secondary. Available at once. D-534.

JUNIOR PHYSICIST experienced in X-rays, spectroscopy and elec. measurements available for research lab. or instructorship. M.S., Purdue, 1932. Speaking and reading knowledge of German and Spanish. At present asst. in physics. Available July. C-7387.

ELECTROCHEMICAL ENGR., 26, single. B.S. in E.E. and Ch.E. 3 yr. experience as field service engr., recording and controlling instruments. Also some sales. Refrigeration, time study and industrial engg. training. D-507.

GRAD. E. E., 1931, 24, specialized in hydraulics. Has had experience in large hydro plant. Desires position in the elec. industry. Location, immaterial. Available immediately. D-543.

E.E. GRAD., 1929; 27. 2 yr. on test floor of Westinghouse; also knowledge of radio and sound reproducing equip. Will accept small salary. Location, immaterial. Available now. D-542.

JR. ENGR., 22, single; 1932 grad. Desires position in elec. industry, preferable radio or one of its affiliated branches. Licensed radio operator. Salary secondary to opportunity. Available on short notice. Location, U.S. or foreign. D-544-323-C-1-San Francisco

GRAD. E.E., 1929, single, 23. 15 months student engr. on G.E. Test. Some test, drafting, and switchboard construction experience before graduation. Interested in position with concern doing consulting or construction work or with utility or mfr. Available at once. Location, anywhere in U.S. but New England preferred. C-8028.

E.E., Cornell Univ., 1931, E.E. deg., single, 22. Holds limited broadcast operator's license. Desires position in any elec. engg. field. Available immediately. D-519.

E.E. GRAD., 1931 M.I.T. (communications), 23, single. Radio experimenter for 10 years. Experience in radio repairing. Desires employment preferably in research or design work with radio, elec. instrument, television, or sound concern. East preferred, but elsewhere considered. Salary secondary. Available on short notice. D-553.

E.E., GRAD. 1929, 25, single, Phi Kappa Phi. 11 months, G.E. Test followed by 2 yr. on G.E. switchgear engg. covering application, development, testing, specifications, field servicing. Good scholastic and efficiency record. Desires connection with utility or engg. corp. Willing to start at bottom. U.S. or foreign. D-560.

E.E. GRAD., 1931, Univ. of Wash., 22, single. Will accept any position, any location. Research preferred. Good scholastic record. D-569.

GRAD. E.E., Stanford Univ., single, 24, desires connection with utility, sound picture industry, or radio mfg. firm. Experienced in genl. office work. Good draftsman. Location, immaterial. D-571.

E.E. GRAD., 1931, midwestern col., single, 24, American. Excellent scholastic record. Desires teaching opportunity. Will teach E.E., mathematics or mechanics. Location, immaterial. D-570.

E.E. GRAD., 1930, 23, single, 15 months on G. E. Test giving test experience with railway equipment, rectifiers, industrial apparatus, industrial control, and refrigeration developmental. Desires position with utility or mfg. concern. Available at once. D-409.

GRAD. E.E., 1931, midwestern col., 4, single. 3 yr. experience in genl. maintenance, construction and motor testing. Location, immaterial. Available at once. D-572.

E.E. GRAD., 1931, Lehigh Univ., 22, single. Summer experience with utility or industrial concern. Eastern states preferred, but other locations considered. Available at once. D-301.

E.E. GRAD., 1931 from Worcester Poly. Inst., member Sigma Xi, 22, single, desires connection with utility concern, industry, or with teaching, also interested in drafting. Location, immaterial. Available at once. D-228.

E.E. GRAD., Univ. of Pittsburgh, '31, cooperative col., single, 23. Westinghouse test and Bell Telephone experience. Desires many kind of engg. or engg. sales work in Eastern part of U.S. D-594.

E.E. GRAD., 1930, E.E., 1931, from Univ. of South Carolina, 23, single. 6 months' experience with South Carolina Pwr. Rate Investigating Committee. Able and willing to do practically any type of engg. work. Available immediately. Location, immaterial. Can give best of recommendations. D-595.

### Research

RESEARCH AND PATENT ENGR. in radio and television field as well as in genl. elec. engg. seeks permanent connection with a stable organization. D-516.

E.E. GRAD., M.I.T., cooperative, 28, single, 4 yr. experience in planning section of large utility making transmission studies, field tests, and foreign wire relations. Wants connection with ry., utility, or mfr. anywhere in U.S. Available on short notice. D-536.

### Sales

MANUFACTURERS AGT. OR SALES ENGR. Southern Calif., 48, 10 yr. engg. work, 12 yr. sales including 5 yr. South Am., good ability, integrity, personality, and knowledge of Spanish, used to pioneering and hard work, salary or commission, part or all time. B-9095.

# Membership

## Recommended for Transfer

The board of examiners, at its meeting held March 2, 1932, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the assistant national secretary.

### To Grade of Member

Armstrong, Emerson A., mgr., pwr. sales, Pub. Serv. Co. of Northern Illinois, Chicago
Bunch, Charles H., secy.-treas., Acme Elec. & Mfg. Co., Cleveland, O.
Chatham, Clyde L., engr., Pub. Serv. Elec. & Gas Co., Newark, N.J.
Ebert Edward, Jr., asst. engr., Bklyn. Edison Co., Brooklyn, N.Y.
Grandy, Lewis S., assoc. prof. of elec. engg., Texas Tech. Col., Lubbock, Texas
Hauser, Oscar E., engr., meter dept., Detroit Edison Co., Mich.
Manby, A.W., supt., Chatts Falls Dev., Hydro. Pwr. Comm. of Ontario, Fitzroy Harbour, Ont.
Morrison, John W., ch. engr., Rochester Telephone Corp., N.Y.
Parmenter, Robert J., designing engr., Pub. Serv. Co. of Northern Illinois, Chicago
Pierce, Donald A., engr., inductive coordination Pub. Serv. Co. of Northern Illinois, Chicago
Schneider, Matthew S., operating engr., Union Gas & Elec. Co., Cincinnati, O.
Tarboux, Joseph G., prof. in charge of elec. engg. dept., Univ. of Tennessee, Knoxville

## Applications for Election

Applications have been received by the secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the assistant national secretary before April 30, 1932.

Andersen, A. W., University of Mich., Ann Arbor.
Armstrong, R. W., Elec. Installation Co., Boston, Mass.
Ballard, H. N., Puget Sound Pwr. & Lt. Co., Seattle, Wash.
Barrett, C. B., Western Elec. Co., Kearny, N. J.
Bateman, I. L., City of Los Angeles, Calif.
Beall, M. F., Univ. of Mich., Ann Arbor.
Bell, G. M., Canadian Westinghouse Co., Hamilton, Ont.
Beyer, N. S., Price Waterhouse & Co., San Francisco, Calif.
Bissell, C. H. (Member), Crouse-Hinds Co., Syracuse, N. Y.
Blackmon, H. N. (Member), Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
Bugnion, F. E., 14 Clinton St., Cambridge, Mass.
Callicott, J. B., Pub. Service. Co. of No. Ill., Northbrook.
Caplow, A. I., 10010 Parkgate Ave., Cleveland, Ohio
Carlson, C. N., 264 Glenwood Ave., E. Orange, N. J.
Church, P. T., Kim Bean Co., Kim, Colo.
Clark, H. D., Conn. Lt. & Pwr. Co., New Britain.
Coe, J. C., War Dept., Wright Field, Dayton, Ohio
Cook, F. R., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
Craig, R. M., Hartford Steam Boiler Inspec. & Ins. Co., Pittsburgh, Pa.
Cramer, H. B., Brooklyn (N. Y.) Edison Co.
Dame, F. E., New York (N. Y.) Edison Co.
Dean, C. F., Chevrolet Motor Ohio Co., Toledo
Dee, T. C. (Member), 808 Third St., Jackson, Mich.
Devitt, W. E., Gen. Elec. Co., Schenectady, N. Y.
Dilley, B., Union Gas & Elec. Co., Columbia Park, Ohio
Dozer, H. E., Nat. Elec. Prod. Corp., Cleveland, Ohio
DuBois, W. R., DuBois Radio Serv., Mogadore, Ohio
Eggleston, L. A., Cornell Univ., Ithaca, N. Y.
Engster, F. W., Gen. Elec. Co., Schenectady, N. Y.
Ewald, G. A., Pub. Serv. Elec. & Gas Co., Newark, N. J.
Ferrin, A. J., 502 North Jackson, Pratt, Kans.
Fey, H. J., Univ. of Wash., Seattle.
Forbes, A. G., Fred Hall's Ranch, Eden, Tex.
Freeman, E. D., Okla. Gas & Elec. Co., Oklahoma City.
Frederiksen, V., Nat. Armature & Elec. Wks., Bluefield, W. Va.
Gaskins, D. W., Harry Alexander, Inc., Washington, D. C.
Gay, T. R., Standard Stations Inc., Pasadena, Calif.
Gierisch, W. C., Houston Ltg. & Pwr. Co., Texas
Goloff, M. J., Can. Westinghouse Co. Ltd., Hamilton, Ont.
Gomez-y-Gomez, T., 630 Terrace Place, Schenectady, N. Y.
Grant, C. A., 726 Univ. Ave., Syracuse, N. Y.
Grooms, A. O., Circuit Breaker Co., Columbus, Ohio
Haas, A. H., Brigham Sheet Gelatine Co., N. Y. City
Habich, C. A., Ewing Von Allmen Dairy Co., Cecilia, Ky.
Harrison, W. P., Okla. Gas & Elec. Co., Oklahoma City
Hartman, F. E., 2307 No. 40th St., Milwaukee, Wis.
Hartmann, C. S., Iowa State Col., Ames
Helfter, F. J., Pac. Tel. & Tel. Co., Santa Clara, Calif.
Heller, W. C., Commonwealth of Pa., Dept. of Labor & Industry, Harrisburg
Helwig, W. O., Speer Carbon Co., Milwaukee, Wis.
Henderson, J. T., Gen. Elec. Co., Schenectady, N. Y.
Hinde, E. J., Univ. of Wash., Seattle
Hoefer, E. G., Jr., 615 Park Place Dr., Chapel Hill, N. C.
Hoenie, N. J., Lincoln Elec. Co., Cleveland, Ohio
Hogg, R. T., Chicago Dist. Elec. Gen. Corp., South Chicago, Ill.
Holtz, C. F., New York Central R. R., N. Y. City
Hosselbarth, G. J., 1916 Himrod St., Bklyn., N. Y.
Hughes, J. S., Southern Bell Tel. & Tel. Co., Atlanta, Ga.
Ibach, W. R., The Milwaukee Elec. Ry. & Lt. Co., Wis.
Johnson, F. C., Stanford Univ., Stanford Univ., Calif.
Johnson, G. C., Mich. Bell Tell. Co., Detroit
Jones, E. R., Kansas City Pwr. & Lt. Co., Mo.
Kalachov, P. D., Univ. of Mich., Ann Arbor
Keachie, E. C., State of Calif., Los Angeles
Kennedy, E. F., Jr., 1624 E. 8th St., Des Moines, Iowa
Kiger, T. E., Mt. Airy, No. Car.
Knapp, D. A., Univ. of Calif., Berkeley
Knudson, C. M., Nevada Mass. Co., Mill City, Nevada
Koso, K. W., Kansas City Pwr. & Lt. Co., Mo.
Kriebel, W. K., Eastern State Penitentiary, Graterford, Pa.
Kullgren, G. V., Shell Petroleum Products, Loveland, Colo.
Lamm, R. H., E. Howard Clock Co., N. Y. City
Larson, L. J., Hexcel Radiator Co., Milwaukee, Wis.
Leeming, H. H., E. J. Cheney, N. Y. City
Leggett, F. E., 940 Jefferson Ave., Gainesville, Fla.
Lehikoinen, R., 380 South St., Fitchburg, Mass.
Levine, V. A., Brooklyn (N. Y.) Edison Co.
Lorenzen, L. M., Rockwell, Iowa
Luckert, A. A., 159 Russell St., Bklyn., N. Y.

McCartin, C., Barber Colman Co., Rockford, Ill.
McClavin, S. I., Rochester Telephone Corp., N. Y.
McKinney, F. L., Southern Bell Tel. & Tel. Co., Ashland, Ky.
McKinney, J. E., Bell Tel. Co. of Can., Toronto, Ont.
McLean, W. H., Harvard Univ., Cambridge, Mass.
Metcalf, D. J., 2131-3rd Ave. West, Vancouver, B. C., Can.
Micka, T. J., Baker, Mont.
Mitchell, H. C. (Member), Brooklyn (N. Y.) Edison Co.
Moauro, J. S., 50 Cherry St., Springfield, Mass.
Moore, J. F., Univ. of Toronto, Ont., Can
Morse, W. R., Univ. of Wash., Seattle
Murray, W. R., Univ. of Mich., Ann Arbor
Myers, R. R., Elec. Maintenance & Engg. Wks., Woonsocket, R. I.
Osterholtz, F. F., Westinghouse X-Ray Co., Inc., Cincinnati, Ohio
Paintin, E. L., Ill. Bell Tel. Co., Chicago
Palo, G. M., Puget Sound Pwr. & Lt. Co., Seattle, Wash.
Parrish, D. B., 9423-58th Ave. So., Seattle, Wash.
Pepall, J. R., Univ. of Toronto, Ont., Can.
Peterson, P., Gen. Control Corp., Minneapolis, Minn.
Peterson, R. M., Griswoldville, Mass.
Peterson, R. A., Route 4, Idaho Falls, Idaho
Peterson, S. R., Long-Bell Lumber Co., Longview, Wash.
Phelan, D. W., P. B. Kelley & Sons, Inc., Syracuse, N. Y.
Pieper, E. J., Van Horne, Iowa
Pokorney, H. F., 3 Sellwood Bldg., Duluth, Minn.
Pratt, E. J., Brooklyn (N. Y.) Edison Co.
Quigley, F., Am. Tel. & Tel. Co., Cleveland, Ohio
Rabuck, G. D., Pub. Serv. Co. of No. Ill., Chicago
Rahill, E. J., New York Tel. Co., Albany
Ramsey, W. S., Town of Morristown, N. J.
Reynolds, F. I., R. F. D. No. 2, Glens Falls, N. Y.
Rising, W. G., Colgate-Palmolive-Peet Co., Kansas City, Kans.
Rivera, J. J., 223 E. 126 St., N. Y. City
Rockefeller, R. W., Univ. of Michigan, Ann Arbor
Root, C. W., Scintilla Magneto Co., Sidney, N. Y.
Rudder, E. J., 714 W. Elm, Enid, Okla.
Rupp, R. H., Am. Tel. & Tel. Co., Cleveland, Ohio
Russell, E. H., 1437 Wyandotte Ave., Lakewood, Ohio
Samson, V. L., Univ. of Mich. Hospital, Ann Arbor
Sanning, F. G. Cincinnati & Suburban Bell Tel. Co., Cincinnati, Ohio
Sargent, H. C., Jr., Univ. of Wisconsin, Madison
Schaeffer, R., Okla. Gas & Elec. Co., Okla. City
Schmidt, F. L., New York (N. Y.) Steam Corp.
Schroeder, W., Univ. of Idaho, Moscow
Schwartz, P. W., Holland Furance Co., Columbus, Ohio
Schwennker, C. H., United Elec. Lt. & Pwr. Co., N. Y. City
Scott, G. G., Gen. Motors Corp., Detroit, Mich.
Scussell, J. J., 35 Gray St., Providence, R. I.
Segal, B., United Elec. Lt. & Pwr. Co. N. Y. City
Shelley, P. L., Okla. Gas & Elec. Co., Enid
Shepherd, S. G., Sask. Pwr. Comm., Shellbrook, Sask., Can.
Shiner, F. L., 6836 Montgall St., Kansas City, Mo.
Simon, G. E., Welda, Kans.
Sittel, V. J., Okla. Pipe Line Co., Muskogee
Sitz, E. L., Kansas State Col., Manhattan
Smith, C. A., 7 Oak Terrace, E. Lynn, Mass.
Smith, E. I., Western Union Tel. Co., Jacksonville, Fla.
Snoddy, B. L., Gen. Elec. Co., Butte, Mont.
Soutter, R., Jr., Okonite-Callender Co., Paterson, N. J.
Spahr, W. H., Metropolitan Life Ins. Co., N. Y. City
Stallman, A. C., Pub. Address System Installations, Ithaca, N. Y.
Stewart, C. F., U. S. Engrs., Catlettsburg, Ky.
Stokes, H. E., Pa. Central Lt. & Pwr. Co., Altoona
Stone, R. W., Oswego Motor Co., N. Y.
Takacs, G. J., Union Gas & Elec. Co., Cincinnati, Ohio
Teece, E. R., Saskatchewan Pwr. Comm., Regina, Sask., Can.
Teskey, C. H., Am. Tel. & Tel. Co., Cleveland, Ohio
Thomas, M. A., Consolidated Mining & Smelting Co., Trail, B. C., Can.
Thomas, T. R., Texas Agri. Dept., Austin
Thomas, W. S., Detroit Edison Co., Trenton, Mich.
Titus, H. W., Lux Fire Protection Equip., Bklyn, N. Y.
Van Aken, H. N., Union Switch & Sig. Co., Swissvale, Pa.
Waldron, C. J., Univ. of Ill., Urbana
Walker, H. H., 1106 Farnam St., Omaha, Neb.
Walters, T. R., Gen. Elec. Co., Pittsfield, Mass.
Wegner, E. A., Armour Inst. of Tech., Chicago, Ill.
Woodford, A. G., Allen Bradley Co., Milwaukee, Wis.
Wright, H. D., Pac. Gas & Elec. Co., San Francisco, Calif.
Zacherl, F. A., 128 Main St., Clarion, Pa.
Zwicker, F. W., Bethlehem Shipbuilding Corp., Quincy, Mass.

# Engineering Literature

## New Books

### In the Societies Library

Among the new books received at the Engineering Societies Library, New York, during February are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no reponsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

RAILROAD CONSTRUCTION, Theory and Practise. By W. L. Webb. 9th ed. N. Y., J. Wiley & Sons, 1932. 8x5 in., leath., $6.00. Pt. 1, 699 p.; Pt. 2, Tables, 226 p.—Deals with all phases of construction from the preliminary survey to the completion of the road and provision of the rolling stock. The present edition is largely new, the author having incorporated improved methods devised in recent years. Necessary mathematical tables are included.

MODERN DIESEL, a review of high speed compression ignition engines. London, Iliffe & Sons., Ltd., 1932. 142 p., 8x5 in., cloth, 2s 6d.—An elementary handbook on the origin, principles of construction, and its advantages. The principal types for automobiles, aircraft, and marine service are described briefly.

HUMAN ENGINEERING. By H. Myers. N. Y. & Lond., Harper Bros., 1932. 318 p., 8x6 in., cloth, $3.—The author, a physician, and management engineer, discusses the management, hygiene, and other topics pertaining to personnel problems.

HEAT ENGINES. By S. H. Moorfield and H. H. Winstanley. London, Edward Arnold & Co., 1931. 287 p., 8x5 in., cloth, $2.25.—An elementary textbook. Presenting the underlying principles clearly and concisely.

GRAPHIC STATICS. By S. Fairman and C. S. Cutshall. N. Y. & Lond., McGraw-Hill Book Co., 1932.—145 p. 9x6 in., cloth, $1.75.—The distinguishing feature is the grouping of three important topics in one volume. The book represents the course offered to engineering students at Purdue University.

ELEKTRISCHE HOCHLEISTUNGSÜBERTRAGUNG AUF WEITE ENTFERNUNG. By R. Rüdenberg. Berlin, J. Springer, 1932. 370 p., 9x6 in., cloth, 31.50 rm.—A series of lectures upon the problems of long distance power transmission, given under the auspices of the Electrical Engineering Society of Berlin and the Berlin Engineering University, by experts from the large electrical companies; discusses in a practical way the theory of a-c. transmission and of long lines, generators, and transformers, compensation, regulation, interconnection, breakdowns, and the economics of a-c. and d-c. transmission.

ECONOMICS OF PUBLIC UTILITIES. By L. R. Nash, 2nd ed. N. Y. & Lond., McGraw-Hill Book Co., 1931. 508 p., 9x6 in., cloth, $4.—To provide in one volume a comprehensive treatment of the underlying economic facts governing public utility considered as a business. Carefully revised and a chapter upon holding companies added. New material upon political activities and agitations against public utilities, legislation on interstate transportation, natural gas movements, and electric power transmission, also has been added.

COMMUNICATION ENGINEERING. By W. L. Everitt. N. Y. & Lond., McGraw-Hill Book Co., 1932. 567 p., 9x6 in., cloth, $5.—A text-book covering the fundamentals of communication by wire and wireless networks which aims to provide a balanced course stressing broad principles rather than specific applications. Author believes the work will be valuable also to the power field, as communication systems and power systems differ primarily in the complexity of their networks.

BEITRÄGE ZUR GESCHICHTE DER TECHNIK UND INDUSTRIE, V. 21. Ed. by C. Matschoss. Berlin, VDI-Verlag, 1931–2. 188 p., 12x8 in., cloth, 10.80 rm.—The 21st volume of annual of engineering history; contains a number of valuable papers, a review of articles published elsewhere, reports on existing ancient engineering works and on museums of industry, and a bibliography of historical publications of the year. Essays on the discovery of magnetic induction development of electric heating during the nineteenth century, early knowledge of the magnetic compass, the development of reinforced concrete, and the history of hydraulic works in China.

### Engineering Societies Library

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

MODERN MILLING OF SUGAR CANE. By F. Maxwell. Lond., Norman Rodger, 1931. 423 p., 10x8 in., cloth, 50s net.—A welcome addition to literature of sugar manufacture. Dr. Maxwell confines himself to the latter stage and presents an account of milling practise in the leading sugar-producing countries. The machinery used is freely described, including prime movers and such topics as electric drives, the operation of milling trains, and milling control.

COLOUR SCIENCE, Part 1. By W. Ostwald. Authorized translation with introduction and notes by J. S. Taylor. Lond., Winsor & Newton, Ltd., 1931. 141 p., 9x6 in., cloth, 15s.—This translation of the first part of "Farbkunde," treating of the theory and standardization of color, has been revised and supplemented by the author.

KINETICS OF HOMOGENEOUS GAS REACTIONS. (American Chemical Society Monograph Series.) By L. S. Kassel. N. Y., Chemical Catalog Co., 1932. 330 p., 9x6 in., cloth, $6.50.—This reviews critically, from a single point of view, information available upon the reaction kinetics of homogeneous gases. The subject is treated theoretically and experimentally in separate sections of the book. The theoretical treatment discusses the principles governing the rates of chemical reaction; the experimental part, all of the available data. Numerous references occur in footnotes.

HILFSBUCH FUR DEN TECHNISCHEN AUSSENHANDEL. By E. K. Lubowsky. Berlin, Hermann Wendt, 1931. 808 p., 10x7 in., cloth, 42 rm.—The purpose of this handbook is to enable the foreign representative of an exporter to anticipate fully the information which the home office must have before it can intelligently submit tenders for machinery or electrical equipment. 450 outlines are given covering various machines. The text is in English, German, French, and Spanish, fully indexed in each.

PLANNING PROBLEMS OF TOWN, CITY, AND REGION. Papers and discussions at the 23rd Natl. Conference on City Planning, Rochester, N. Y., June 22–24, 1931, publ. by Wm. F. Fell Co., Phila., 1931. 228 p., 9x6 in., cloth, $3.00.—Topics discussed are: Is city planning effective control of city growth? Mass transportation on city streets; master plans and official maps; zoning and administration; edges of zones; county planning; relation of special assessments; planning programs for small cities; prevention of blight adjacent to expressways.

RELAY HANDBOOK AND SUPPLEMENTS, 2 ed., 1931. Natl. Elec. Lt. Assn., N. Y. 1381 p., tables, 7x5 in., lea., $4.00 to members; $6.00 to nonmembers.—This new edition consists of a reprint of the handbook with a 367-page supplement and combined index, obtainable as a separate volume.

DIESEL REFERENCE GUIDE. By J. Rosenbloom originally announced in ELECTRICAL ENGINEERING, Jan. 1931, p. 76, now is available at $4 per copy instead of $10 as announced previously. Publishers agents: Rider Press, N. Y.

# Industrial Notes

**New Combination in Copper Field.**—Effective March 21, the newly formed Phelps Dodge Copper Products Corporation took over and will operate the following fabricating units as divisions: the American Copper Products Division, with mills at Bayway, N. J., manufacturers of copper rods, bus bars, trolley wire, weather proof wire, etc.; The British American Tube Division, Bayway, N. J., condenser tubes, copper tubes, and pipe, etc.; Inca Manufacturing Division, Fort Wayne, Ind., enameled copper wire, coils, and magnet wires; P-M-G Metal Division, Bayway, N. J., copper and copper alloy products.

The Habirshaw Cable and Wire Corporation will maintain its separate corporate existence and will be operated as a subsidiary of Phelps Dodge Copper Products Corporation. With mills at Yonkers, N. Y., and Bridgeport, Conn., it manufactures rubber and lead covered copper wire, paper, and varnished cambric insulated power cables, and other electrical conductors.

The name of the present fabricating subsidiary, National Electric Products Corporation, will hereafter be the corporate title of the National Metal Molding Division of the company only, with headquarters at Pittsburgh. Its plant is at Ambridge, Pa., and the principal products are rigid and flexible steel conduits, metal molding, outlet boxes, etc. Wylie Brown is president of both the Phelps Dodge Copper Products Corporation and the Habirshaw Cable and Wire Corporation. Both companies have moved their offices and are now located at 40 Wall Street, New York. Through acquisition of the Calumet and Arizona Mining Company, and prior acquisition of the Nichols Copper Company and the National Electric Products Corporation, Phelps Dodge Corporation is one of the three large units in the copper industry in the United States.

**New Disconnecting Link Boxes.**—The G & W Electric Specialty Company, 7780 Dante Avenue, Chicago, has developed a new device for simple and economical sectionalization of high tension cables. It is an oil-filled, disconnecting link box, comprising an assembly of standardized parts, and is produced at low cost to meet individual requirements.

**New Electrode for Welding Aluminum.**—The Lincoln Electric Company, Cleveland, Ohio, announces a new electrode for welding aluminum which will be known as "Aluminweld." The new electrode is a 5 per cent silicon aluminum alloy; can be used for welding sheet or cast aluminum, and is designed for either metallic or carbon arc welding.

**A New Vacuum Contact Relay.**—The Ward Leonard Electric Company, Mount Vernon, New York, has added a vacuum contact relay to its line of midget relays. The vacuum contact element, which is actuated by the relay armature, is rated at 8 amperes intermittently and 6 amperes continuously at 220 volts. Relays equipped with this type of contact are especially applicable to operation in hazardous places and have a high rating, making them a heavy duty midget relay. These relays may be obtained for normally open or normally closed operation. Coils may be wound for 6 to 110 volts alternating or direct current.

**A New Mercury Switch.**—The CeCo Manufacturing Company, Inc., Providence, R. I., has formed an industrial division to develop electrical and electronic devices for industrial purposes. One of the products of this division is the "Mertact," a mercury electric switch. Mertacts are made in sizes from 1 to 100 ampere capacities. Sizable currents can be broken by a very small mechanical force, often eliminating the necessity of using intermediate relays. The new switch has a wide field of application in electric appliances, heating devices, automatic temperature control, and in equipment that requires frequent make and break of current. C. O. Cressy will be the engineer in the industrial division assigned to the application of this division's products.

**Outdoor Switch Houses.**—The Delta-Star Electric Company, Chicago, has developed a line of metal clad, outdoor switch houses for medium capacity distribution circuits. They are equipped with T.P.S.T. solenoid operated, trip-free oil breakers, rated 7.5 kv., 400 ampere interrupting capacity 30,000 kva. The circuit breakers are controlled from the switchboard substations. Space above the operating mechanism provides for instruments, relays, reclosing timer, control switch, etc., converting the units to full-automatic and self-contained if required. Front and rear doors give ready access to all parts for inspection. Manual, d-c. solenoid, a-c. and d-c. trip-free motor mechanisms are available. The houses are compact, well constructed, low in first cost and maintenance.

**W. M. Bailey Now Chief Engineer of Dubilier Condenser Corp.**—William Mason Bailey, formerly with the Wireless Specialty Apparatus Company, of Boston, has been appointed chief engineer of the Dubilier Condenser Corporation in New York City. In collaboration with William Dubilier and the engineering staff of the organization, Mr. Bailey has in large measure been responsible for recent Dubilier developments such as the standard unit oil condenser, the moulded micadon, the ultra high frequency capacitors and the improved electrolytic condensers.

Officers and Committees (For complete listing see p. 71–76, January 1932 issue of ELECTRICAL ENGINEERING.)

DEVELOPMENT of a high degree of reliability in the low-voltage a-c. network required the development of a network protector having special characteristics. Various methods of obtaining these characteristics are used by the different manufacturers. *p. 307–312*

MORE ACCURATE calculation of conditions on power systems after the occurrence of a fault now can be made by the use of revised standard decrement curves developed jointly by General Electric and Westinghouse engineers. *p. 324–329*

ELIMINATION of a series of severe arc-overs caused by lightning surges entering a distribution substation has been secured by shunting low voltage lightning arresters across the regulator series winding and by connecting lightning arresters at the substation end of the entrance cable. *p. 304–306*

CLEVELAND, Ohio, "the forest city" situated on the south shore of Lake Erie, will be host to the summer convention of the Institute June 20–24, 1932. In addition a most complete technical program, many vacation features and novel entertainments are being arranged. There will be no registration fee. *p. 346–348*

MANY interesting discussions took place at the recent meeting of the Institute's Great Lakes District in Milwaukee, Wis., March 14–16, 1932. The principal of these are summarized in this issue. *p. 348–350.* The concluding section of summaries of winter convention discussions also is given. *p. 350–353*

INTEREST in the "Letters to the Editor" section is constantly growing, and members are taking advantage of this opportunity to express themselves briefly and informally on a variety of topics. *p. 354–355*

ONE ASPECT of the banking and investment situation is stated clearly in an editorial recently printed in *Engineering News-Record*. Bankers, it is claimed, are responsible for the failure of many investments abroad, due to their unwillingness to take advantage of expert engineering advice. *p. 353–354*

GAS FILLED tubes have characteristics which make them adaptable to many rectifier, inverter, and control applications. Also, the capacity of the electron tube has been increased manyfold by filling with gas or vapor, and the sensitivity by which these tubes may be controlled is being developed constantly. *p. 312–318*

THE PART that engineering and engineers may play in the stabilization of industry is discussed in the tenth article in the Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?" contributed by William Green, president of the American Federation of Labor. *p. 318–319*

AN INNOVATION has been introduced by the use of alternating current for the operation of supervisory control systems. Furthermore, these systems may possess great reliability, and arrangements may be made for the operator to visualize switching conditions at a glance. *p. 329–331*

ELECTRICAL and magnetic units are being subjected to careful scrutiny at all times; they are discussed in four articles presented in this issue. *p. 335–345*

PARAGUTTA, an improved insulating material for submarine communication cables, has made it possible to obtain three telephone channels in a cable but little larger than the older single-channel gutta-percha cables. *p. 332–335*

OPEN-CIRCUIT remanence of a permanent magnet and the manner in which it is affected by various factors is a study of prime importance to magnet manufacturers and users. These factors include the magnetic properties of the steel itself and the shape and size of the magnet, all of which can be controlled in the design and manufacture. *p. 320–323*

# Weather Resistant Covering for Line Wires

**Previous to the last two years, development of weather resistant covering for line wires lay in the hands of the manufacturer and was centered upon meeting the demand for a cheaper product. This resulted in a decreasing life of the covering. Research described in this article points the way to a greatly improved covering which, although slightly more expensive to produce, can be justified economically by its longer life and higher insulating quality. Specifications for the saturant of such a covering are presented herewith.**

DURING the years following 1918 or 1920 effort was concentrated upon the reduction of cost of weather resistant covering for line wires. This resulted in the early loss of saturating compound and the shedding of braids, in many cases within a period of two or three years after the erection of the lines. Sentiments of many operating engineers therefore swung toward discontinuing a weather resistant covering on overhead lines and adopting bare conductors for all service except where tree wire was necessary or where highly insulated conductors were required at points of inadequate spacing or clearance.

Certain engineers opposed the policy of abandoning the use of weather resistant coverings on overhead lines having a line-to-line voltage of 4,000 or less, for the reason that such a covering might reduce the number of service interruptions by preventing grounds and short circuits. This group believed that an attempt should be made to improve weather resistant coverings before making a decision to discontinue their use. At the suggestion of engineers in the group of companies represented on the Utilities Research Commission, the latter initiated a study at Purdue University to develop weather resistant wire covering providing longer life and higher insulating value. This study was started October 1, 1929, under the direction of the electrical division of the engineering experiment station with the chemical division cooperating. Work already completed enables the following definite conclusions to be drawn:

1. The present triple braid weatherproof wire covering may be materially improved by using as saturants higher fusing-point blown asphalts, free of waxes, and of low boiling fluxes. Such saturants will provide a covering of uniformly long life.
2. These improvements can be secured at only a slightly increased cost.
3. The higher saturating temperatures required to apply such saturants may be used without damage to the cotton yarns and without excessive annealing of the copper conductors.
4. As a result of this work, a preliminary specification for the saturant of weatherproof coverings is presented in this article, and includes terms which guarantee weatherproof wire of long life.
5. Future work will provide a covering of lighter weight and smaller size, but of higher insulating value and longer life than present construction.

Economic studies have proved that these results justify an increased cost of weather resistant wire covering, provided the improvements of higher insulating value and longer life now available are incorporated during manufacture.

### Preliminary Specification for Weatherproof Wire Saturant

The saturating compound shall consist of a pure blown petroleum asphalt and shall not be mixed with any material such as paraffin, wax tailings or fluxes. It shall have the following physical properties:

**Ball and Ring Fusing Point:** 180–200 deg. fahr.

**Penetration:** 77 deg. fahr., 100 g., 5 sec., 35 or harder, tenths of mm.

**Pliability:** A mold of the asphalt $^1/_4$ x 1 x 4 in. shall not break when subjected to an angle of bending of 15 deg. around a mandrel of $^3/_{16}$ in. radius at a temperature of 0 deg. fahr. This test shall be made in the Reeve and and Yeager pliability testing equipment, at a rate of bending of 10 deg. per min.

**Loss by Evaporation:** A 100 g. sample of the compound heated for 100 hrs. at a temperature of 325 deg. fahr. shall not lose more than 1.0 g. in weight.

**Rise in Fusing Point:** The difference in the ball and ring fusing point determined before and after the above heating test shall not be greater than 40 deg. fahr.

**Change in Penetration After Heating:** The penetration of the sample subjected to the above heating test shall not become harder by more than 10 points. The crust formed on the sample during the heating test may be removed before determination of the penetration after heating.

---

Written especially for ELECTRICAL ENGINEERING, based upon "Weather Resistant Covering for Line Wires" (No. 32-56) presented at the A.I.E.E. Great Lakes District meeting, Milwaukee, Wis., March 14–16, 1932, and subsequently brought up to date by the inclusion of later test results and definite specifications. *Not published in pamphlet form.*

## LABORATORY EQUIPMENT

Complete testing equipment was purchased or constructed for the laboratory at the university, as it was found that no adequate equipment was available in the plants manufacturing weather resistant wire in the United States. Accelerated weathering equipment therefore was installed for testing the comparative length of life of completed wires, asphalts, and other saturants, yarns, etc.; this exposes the samples to light from a carbon arc and to a water spray at a constant wire temperature of 175 deg. fahr. during one part of the daily weathering cycle. The samples are subjected to freezing by moving the wire holding drum to a large refrigerator and to thawing and drying by moving back to the light exposure chamber. Distilled water is circulated to the sprays from a storage tank and pressure provided by an auxiliary pump.

A natural weathering rack for completed wires provides continuous current loading and application of line voltage to the wire samples. Service testing equipment for duplicating installation and service conditions includes apparatus for subjecting the wire to abrasion such as occurs when drawn over a crossarm or caused by rubbing on insulators, wrapping and bending at freezing temperatures, and for producing decentralization of the conductor in the covering as occurs in service.

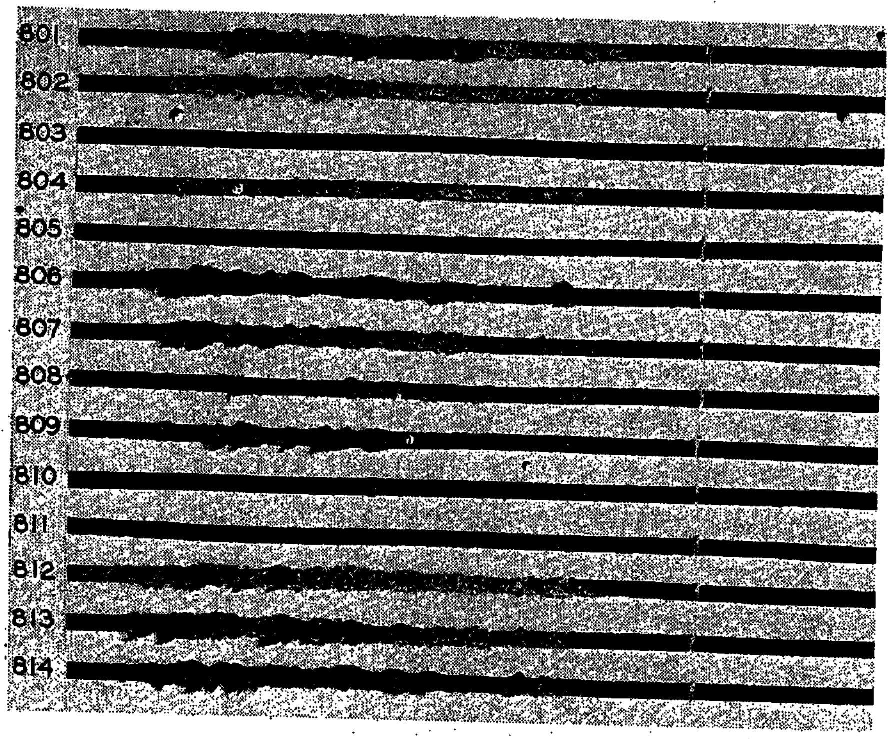

**Fig. 1. Condition after accelerated weathering test of wires saturated with commercial solvents**

Standard physical tests are applied to the saturant as follows:

1. Fusing point is determined by the standard ball and ring method used by the asphalt industry, the fusing point being the temperature at which a steel ball of specified weight drops through a mold of the material under test, the material being supported on a brass ring and immersed in water, the temperature of which is raised at a slow and definite rate.

2. Viscosity of the asphalt at saturating temperatures is determined by the Stormer method, by which it is expressed as the number of seconds required for 100 revolutions of a cylinder propelled by a 100-g. weight and immersed in the material to be tested.

3. Consistency or hardness is determined by use of the Abraham consistometer; this equipment measures the pressure required to force the various sized plungers at a constant rate into the mat under test. Hardness is also measured by the needle penetron commonly used by the asphalt industry. By this method the h ness is the depth of penetration into the asphalt, expressed in te of millimeters, of a standard needle with a weight of 100 g. ap for 5 sec. The lower the penetration number the harder is the terial. In Table I, hardness is expressed in terms of penetratio

4. Pliability at low temperatures is determined by bending a m of dimensions $^1/_4 \times 1 \times 4$ in., broadside about a round man $^3/_8$ in. in diameter while the sample and apparatus are held at low temperature of test. The angle of bend is increased at the of 10 deg. per min. and the angle of bending required to break mold is taken as a measure of the pliability.

The designs for an improved Abraham consistor ter to measure hardness, and for Reeve & Yea pliability test equipment especially adapted to t work, have been completed. The rate of penet tion in the consistometer and the rate of bending the pliability tester will be quite constant, as b are to be electrically driven and the degree of bendi in the pliability test will be determined by automa electric timing of the start and finish of the bendi period. The consistometer hardness will be re from a pressure gage which indicates the pressu on the table of the consistometer supporting t asphalt sample under test.

In the testing of finished wire a small electrical heated braid press and a pliability tester in whi very small samples of asphalt may be tested ha both been completed. The braid press is used extract the saturant from the two inner braids of finished wire. Sufficient asphalt is obtained from 2-ft. length of No. 6 wire for the standard ball a ring melt point test and the penetration determin tion. With this new equipment the pliability te can be made upon the small sample extracted fro the braids.

The commonly used drip and stain tests cann be regarded as tests of the physical properties of t saturants. The high melting wax used as an out coating prevents staining, and the yarns hold t asphalt, preventing dripping even though t saturant may be quite soft. The drip test ma favor also an unsaturated wire.

## PREVIOUS PRODUCTION METHODS

Before the start of the last decade, weathe proof wire coverings usually were built up of braid made from high-strength long-fiber cotton yar often saturated after each braid was applied an usually saturated with natural asphalts rather tha petroleum base asphalts. Production methods wer slow and the materials used more expensive than i is now possible to use. With the start of the las decade the producers of weatherproof wire began t use cheaper grades of cotton yarn and looser braids and for saturants they turned to petroleum by product asphalts. They further changed from th saturation of each braid after its application to th application of all three braids in one step and th saturation of these braids as a second step. To obtain the production speeds required and to saturat three braids in one step at the temperature (that o low pressure steam) available in the wire plants the use of low melting point petroleum asphalts of low viscosity at saturating temperatures became general.

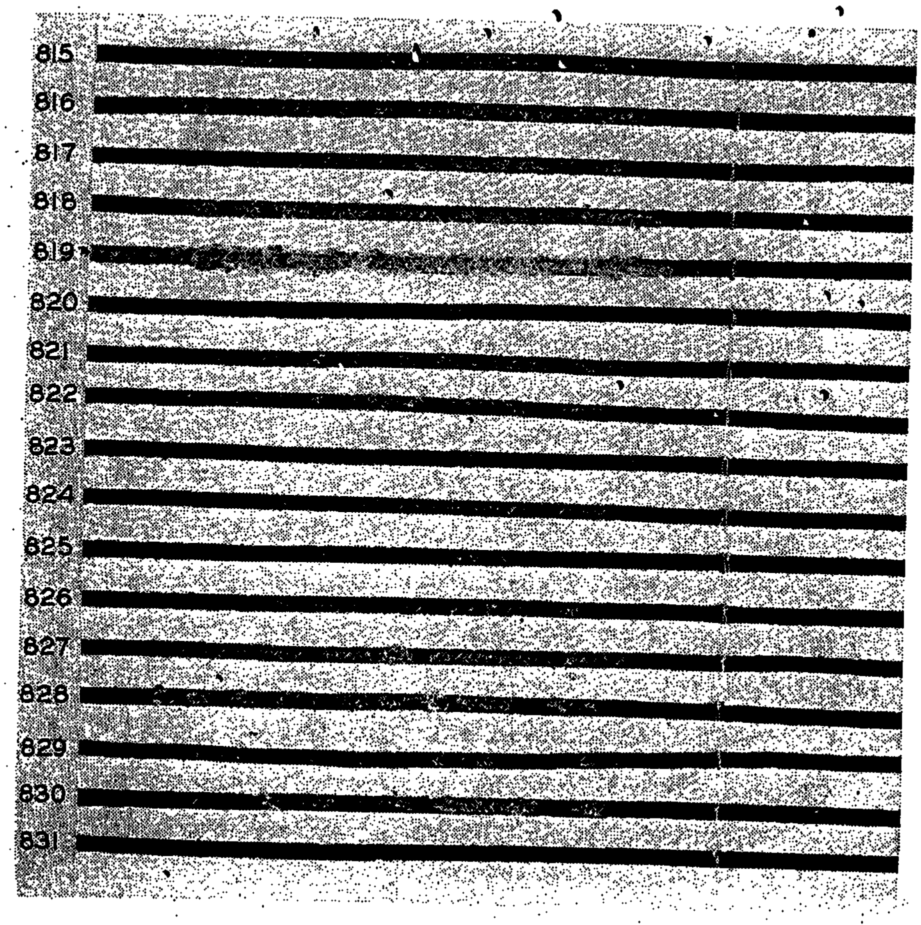

**Fig. 2. Condition after accelerated weathering test of wires meeting various parts of preliminary specifications. Wires 815–8, 820–6, and 830 meet these specifications in every detail**

## SATURANTS CAUSE OF MAJOR FAULTS

The test results indicate positively that the poor physical properties of the saturants used in weather resistant wire coverings in the past have been the cause of the extremely early failure of weather resistant wire. The coverings of wires which last well are eventually caused to fail by a combination of physical changes such as the shifting of saturants in the coverings, etc., and chemical changes in the saturant caused by exposure to light, oxygen of the air, etc. In very early failures the effects of light and oxygen are of less importance than the effects of poor physical properties which cause the saturant to shift in the braid when hot, and to crack and split when cold.

These poor physical properties of the saturants are: too low fusing points, extreme softness when warm, great changes in hardness with changes in temperature, extreme brittleness at even moderately low temperatures, and a marked tendency to evaporate. The majority of saturants used have had softening points (as determined by the ball and ring method) ranging from 130 to 150 deg. fahr., which are lower than maximum wire operating temperatures. These materials shift in the braids leaving the upper braids unprotected at ordinary summer temperatures, which are well below the fusing point. The extreme brittleness of these saturants, resulting in cracking and breaking of the braids in cold weather, may be illustrated by the fact that in the pliability test at 0 deg. fahr., less than 2 deg. bending is required to break the molds of the majority of these saturants.

Many of the poor physical properties, particularly the disappearance or evaporation of the saturant from the braids, have been caused by the addition of excessive amounts of waxes, wax tailings, or low melting fluxes to obtain fluidity and ease of saturation. Usually this addition was made by the workman operating the saturating tank and resulted in a saturant of variable properties. These low boiling materials soon leave the saturant, causing the body of the asphalt to disintegrate. The saturants vary in their resistance to the weathering effects of light and oxygen, and the worst are subject to excessive surface deterioration and erosion. The result of all these factors is the loss of compound, particularly from the upper side of the braids, with the resultant breaking of the braids on the upper side and the familiar festooning.

Finishing waxes cannot be regarded as of great protection to the covering because they evaporate or crack and flake off within a short time, or are damaged in installation. On the various samples in the natural exposure rack, the wax has cracked, chipped off, or simply disappeared from the surface of the wire in from 3 to 8 months.

## COTTON YARNS

It has been found that the cotton yarns are not so important in producing a long-lived covering as are the saturants. It is important, however, that sufficient cotton to absorb and hold the saturant be present in the two inner braids, and that the outer braid be closely woven to resist abrasion and erosion. The one fault of the braided construction is that because of the interstices always present it does not consistently afford insulation beyond that of the air spacing provided. It is desirable to have a more solid and homogeneous material next to the conductor.

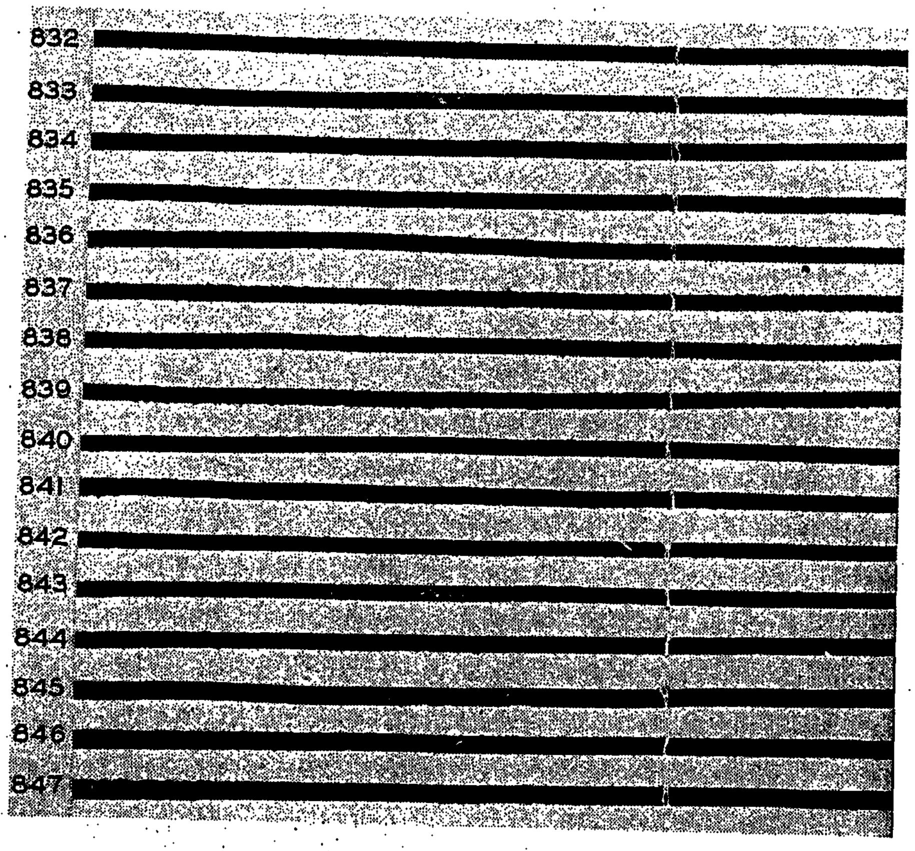

**Fig. 3. Wires illustrating the improved weather resistance of air blown asphalts to which the proper inert mineral fillers have been added**

Table I—Comparison of Physical Properties of Commercial Saturants and Asphalts Proposed as Saturants

| | Range of Physical Properties | | Average of Physical Properties | |
|---|---|---|---|---|
| | Commercial Saturants | Proposed Saturants | Commercial Saturants | Proposed Saturants |
| B. & R. fusing point | | | | |
| Before heating | 119–158°F | 186–208°F | 143.2°F | 196.1°F. |
| After heating | 176–245 | 209–232 | 198.4 | 220.7 |
| Penetration: 77°F., 100 g., 5 sec. | | | | |
| Before heating | 3–66 | 21–33 | 25.5 | 27.5 |
| After heating | | | | |
| with crust | 0–23 | 0–4 | 8.7 | 1.0 |
| crust removed | 0–26 | 17–29 | 11.8 | 22.3 |
| Loss in weight during heating | 0.12% gain, 7.17% loss | 0.03–0.97% loss | 1.63% | 0.36% |
| Pliability | 0.41°–13.3° | 16.2°–48° | 3.21° | 26.5° |
| Specific gravity | | | | |
| Before heating | 1.001–1.200 | 0.987–1.044 | 1.071 | 1.011 |
| After heating | 1.021–1.208 | 0.988–1.042 | 1.080 | 1.013 |

## IMPROVED SATURANTS

The use, as weatherproof wire saturants, of the air blown asphalts meeting the preliminary specification which has been developed, has been proved in the laboratory to yield a greatly increased length of life of the covering on any size of wire over that provided by the usual commercial saturants, and to provide a great increase of flexibility in the finished wire. The physical properties of these asphalts and the present commercial saturants are given in Table 1. The preliminary specification also is given on p. 299.

Such an asphalt, of greater stability at higher wire temperatures, will reduce materially the shift of the saturant in the braids and will be less subject to evaporation and erosion. In addition, these asphalts are less susceptible to temperature changes and are much less brittle at low temperatures. Such asphalts may be bent many degrees in the pliability test, while most commercial saturants cannot be bent more than 2 deg.

These "air blown asphalts" are produced by blowing air through the heated petroleum residue, as compared to the production of the usual commercial saturant by blowing steam through the petroleum residue. Certain changes in the structure of the asphalt are produced by the air blowing which results in a much more stable asphalt of lower temperature susceptibility. The asphalts illustrated in Fig. 2 are stock products; they are not special materials in any sense. There is no reason to think that the increased use of air blown asphalts meeting these specifications will result in a marked increase in cost of the materials (which now cost very little more than the steam reduced asphalts) because the petroleum residue is just as readily blown to meet this specification as one of a lower melting point.

Adequate proof of the betterment obtained by the use of these materials is given by comparing the wires in Fig. 1 with those in Fig. 2, all having had the same exposure in the accelerated weathering test. Fig. 1 shows the condition of wires saturated with the present commercial saturants after having been exposed in the accelerated weathering test at Purdue. The four wire coverings that have held up well on this test are saturated with very hard and very brittle materials. The asphalts with which these four wires are saturated bend less than 2 deg. in the pliability test. This emphasizes the importance of applying both the laboratory pliability test and the accelerated weathering test in choosing the most satisfactory weather resistant coverings. The wires in Fig. 2 have coverings saturated with air blown asphalts meeting the specification for melting point and penetration, but in the case of samples 819, 826–9, and 831 not meeting other parts of the specification such as those for pliability or changes in physical properties with long continued heating. It may be seen readily that the wires meeting the preliminary specification in every detail provide a vast improvement in weather resistance over the commercial saturants; these wires are numbers 815–8, 820–6 and 830. In the pliability test all of these asphalts bend more than 15 deg. and wires saturated with these materials may be bent about their own diameter at freezing, or lower in some cases, without breaking any of the braids.

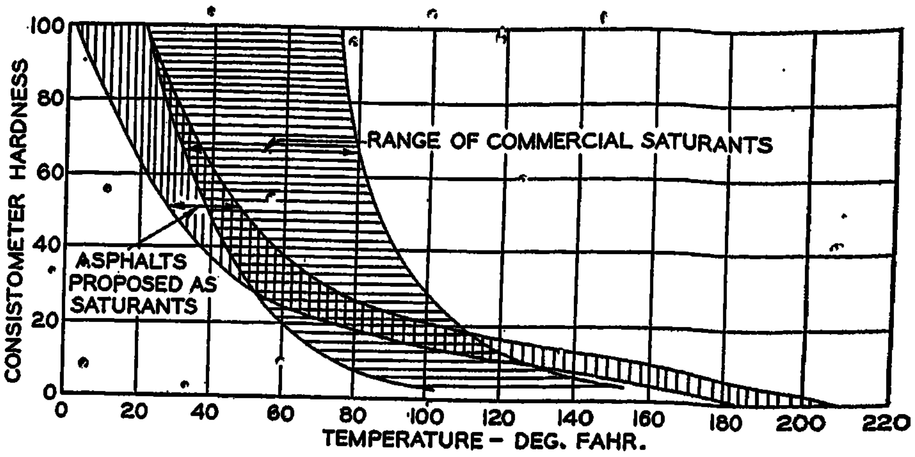

Fig. 4. Comparison of initial hardness

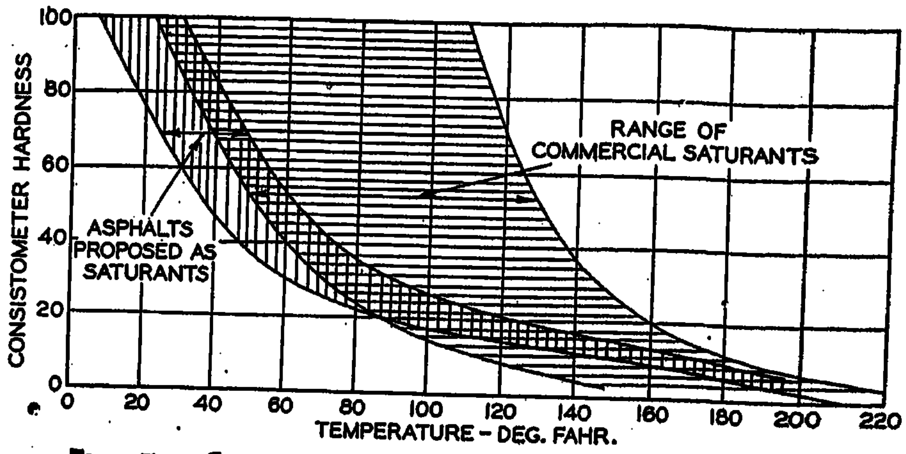

Fig. 5. Comparison of hardness of saturants after heating for 100 hr. at 325 deg. fahr.

Sample 819 is saturated with a material that has shown peculiar breakdown when exposed to light and heat and that has been used in the lower melting point ranges in very great quantities of weatherproof wire in the past 10 years.

The use of the asphalts meeting the preliminary specification requires only a change of saturating temperature and does provide a remarkable improvement in the weather resistance of the covering.

The smaller change with temperature in the hardness of air blown asphalts as compared with the commercial saturants, and also the greater stability at the higher operating temperatures, is illustrated in Fig. 4. It may be seen that the air blown asphalts are harder, as an average, at temperatures of 40 deg.

fahr. and higher; but are softer than the commercial saturants below this temperature. The smaller change in the hardness of the air blown asphalts as compared with the commercial saturants after being heated for 100 hr. at 325 deg. fahr. is shown in Fig. 5. It will be noted that the blown asphalts have not changed greatly, while the commercial saturants have become much harder. This lack of change with long heating has been proved to correlate rather closely with the resistance of the wire covering to weathering.

While all of the asphalts which weather poorly in the wires in Fig. 2 would have been eliminated by requiring them to meet the preliminary specification, it is not yet certain that this will always be true and the accelerated weathering test must still be depended upon to eliminate the poor materials. In the operation of the "weatherometer" on the standard cycle used by the Bureau of Standards, the commercial saturants all show extreme checking or cracking in only one day whereas the asphalts recommended show no signs of deterioration in this time except in one instance, thus checking the tests of the asphalts in wires as illustrated in Figs. 1, 2, and 3.

The analysis of asphalt and the determination of chemical unsaturation now are being carried on to learn if it is possible to correlate some result of this analysis with the variation in weathering.

## SATURATING TEMPERATURES

To obtain thorough saturation of triple braid coverings with saturants of a fusing point of from 180 to 200 deg. fahr. at present saturating speeds, it is necessary to use higher saturating temperatures than are used today. Laboratory tests have shown that to obtain saturation of three braids on No. 6 AWG. conductors in 5 min. requires a saturant viscosity of 100 deg. Stormer, or less. In Fig. 6 is shown graphically the time required to saturate at any given viscosity the triple braid covering on No. 6 AWG. conductors with asphalts of a very wide range. It should be noted that the time of saturation is not the same for all saturants at a given viscosity but varies with the asphalt, some requiring more and some less time.

That higher temperatures are required to obtain saturation of the braided coverings with the air blown asphalts than are required in the case of the commercial saturants is shown in Fig. 7. Viscosities lower than 100 sec. per 100 revolutions are required to obtain saturation of triple braid coverings at present saturating speeds, and temperatures of 360 deg. fahr. and higher are necessary for saturation with these asphalts. A change would be required in the heating equipment for the saturating tanks if such saturants are to be used.

A number of tests was made to determine definitely whether or not saturating temperatures as high as 400 deg. fahr. can be used without damaging the cotton yarns or too greatly annealing the copper conductors. The cotton yarns were tested for tensile strength, heated in air for different times, allowed to regain normal moisture content, and again tested. The tensile strength of oil soaked yarns was also tested and compared with that of similar yarns heated in oil for varying times. No. 6 AWG. copper conductors, both medium hard and hard drawn, were tested for tensile strength after heating in hot oil for varying times, and compared with tests made on unheated conductors. The results of the cotton and copper tests are presented in Tables II and III.

It may be seen that the loss of strength of the cotton yarn is of no importance in even the longest saturating time. There is no appreciable annealing of the copper conductors in the saturating times required in the modern continuous saturating tanks now generally used. In the case of the older type

**Table III—Effect of Saturating Temperature on the Tensile Strength of Copper Conductors**

All Samples Heated at 392 Deg. Fahr.

| Kind of Sample | Tensile Strength Lb. per Sq. In. | Loss in Strength Lb. per Sq. In. | Per Cent Loss |
|---|---|---|---|
| Hard drawn No. 6 copper wire | | | |
| Unheated wire | 63,560 | | |
| Heated 10 min | 62,590 | 970 | 1.53 |
| Heated 30 min | 61,140 | 2,420 | 3.96 |
| Medium hard drawn No. 6 copper wire | | | |
| Unheated wire | 51,430 | | |
| Heated 10 min | 50,780 | 650 | 1.27 |
| Heated 30 min | 49,490 | 1,940 | 3.93 |

"reel in and reel out" saturating tank, the time required for saturating may be long enough to anneal the conductor slightly, requiring that the conductors be drawn somewhat harder initially. It is believed that these tests have definitely cleared the way for the use of higher saturating temperatures in so far as a likelihood of any damage to yarns or conductors is concerned.

### OTHER MODIFICATIONS

The improvement that may be made in the weather resistance of the air blown asphalts by the use of the proper inert mineral filler is shown in Fig. 3. Wires numbers 832–5 are saturated with the same materials as wires 815–8 in Fig. 2 except that 30 per cent by weight of 325-mesh slate dust was added to the asphalt before saturation. Wires 840–2 in Fig. 4 are also asphalts to which certain modifying agents have been added. The use of such modifying materials provides an additional and very desirable improvement in the weather resistance of the wire covering and also may slightly reduce the cost of the saturant because of the cheapness of the slate dust. The use of the filler is particularly helpful in the case of the asphalt on the surface of the wire and in the case of the finishing materials.

Finishing materials that are more flexible than the present waxes may be had and are much more desirable, particularly when some filler is used as a coating or an anti-stick in these finishes. Mica flake is especially valuable as an outer finish.

### NEW AND IMPROVED COVERINGS

The greatly superior insulation of paper tape covered samples with a single weatherproofed outer braid has been shown repeatedly by the slower decrease in insulation resistance of this covering when immersed in water, as compared with the triple braid construction. The use of this paper tape and single braid covering provides a conductor of lighter weight and of much smaller overall diameter, which means that sleet and wind loads will be lower, and also that the conductor will possess consistently high dielectric strength even with considerable exposure of the braids to the weather. Bakelite and other synthetic resins, Harvel compounds and varnishes, and other materials, have been applied to weather resistant wire coverings, and because of the excellent weathering quality of such materials provide a highly protective coating.

Ample proof has been given that the materials recommended herewith will produce longer life in weatherproof wire coverings. Also, these materials may be obtained within a reasonable distance of any weatherproof wire plant in the United States. It is felt that the experience and equipment built up as a result of this work should prove of value in the development of improved weatherproof braids as applied to types of wire other than the ordinary weatherproof wire. This is especially apparent when it is pointed out that in looking for improved materials, the coverings of tree wires and other insulated overhead line wires were investigated to learn if the weatherproofing compounds used in the braids on these wires were superior to the ordinary weatherproofing compounds, and it was discovered that while these coverings were made of exceptionally strong and high grade braids, they were not saturated with compounds in any way superior to the present commercial weatherproof saturants.

# Impulse Tests on a Substation

**Severe flashovers have occurred in ungrounded 4,800-volt distribution substations in Detroit. Impulse tests have proved that these were caused by surges reflected from regulator windings, but can be prevented by the proper placing of lightning arresters.**

DURING the 1928 lightning season the Detroit Edison Company experienced in five substations a total of six arc-overs which were caused by

---

Based upon "Impulse Voltage Tests on a 4,800-Volt Distribution Substation" (No. 31-133) presented at the A.I.E.E. South West District meeting, Kansas City, Mo., October 22–24, 1931.

lightning voltages entering the stations by way of a 4,800-volt ungrounded distribution system. The overhead lines of this system enter the substations through three-conductor underground cables, and lightning arresters are located at each junction of line to cable and at the substation bus. Some of the distribution lines are equipped with three phase voltage regulators in the substations. These regulators are *Y*-connected, but the neutral is not brought out and is insulated from ground. Fig. 1 shows the layout of a typical distribution line with a regulator.

Besides being unusually large in number for a single season, the arc-overs were of unexpected severity. In each case the lightning voltage causing flashover entered the substation by way of a distribution line on which there was a voltage regulator. Furthermore, the flashovers occurred at some point between the substation pothead and the line-side regulator terminals, their nature indicating that they were caused by potentials in excess of the breakdown voltages of the cable pole and bus lightning arresters, which inspection showed to be in good operating condition. This consistency in the location of the flashovers indicated that the surge impedance of the regulator series winding probably was great enough to cause reflections of surges entering the substation, and so to result in the building up of a voltage at the regulator line terminals sufficiently high to cause flashover.

As the result of a series of impulse voltage tests, two forms of protection were found to be effective in preventing the surge voltage rising to values sufficient to break down the entrance cable or cause flashovers at the station end. Low voltage lightning arresters shunted across the regulator series windings operate in series with the bus arrester and limit to the sum of the breakdown voltages of these two sets of arresters the rise of voltage on the line side of the regulator. The second method, and the one which is more desirable because of its insuring a lower voltage at the substation end of the cable, is to connect arresters at this point to ground. They limit the voltage on the substation pothead and on the regulator, and, acting in combination with the arresters on the bus and at the outside end of the cable, the voltage in the station and entrance cables to the drops across the arresters.

## EQUIPMENT USED

The 4,800-volt Elmdale distribution substation is of the open pipe-frame construction, the bus copper and all leads being insulated with varnished cambric. One distribution line with voltage regulator was left in the substation, and its 745-ft. entrance cable was looped back so that both ends were in the station. This was a three-conductor, 200,000-cir. mil, lead-covered cable insulated with oil-impregnated paper $^5/_{32}$ in. thick on the conductors with a $^5/_{32}$-in. over-all belt. A dead 24,000-volt three-conductor cable line 8,900 ft. long terminated in the station and was available during the tests.

The impulse voltages used during the various tests were obtained from a 1,000,000-volt lightning generator and auxiliary equipment. Since only 180,000 volts were required in the tests, the generator was reconnected to deliver this voltage with a capacity of 0.075$\mu$f. During the tests, two portable cathode-ray oscillographs were used, one being an improved Norinder oscillograph, and the other a George oscillograph of the hot cathode type. The apparatus in the measuring system included a resistance potentiometer and a delay cable.

The substation apparatus tested is shown in Fig. 1. Pothead 1 represents the cable pole pothead of the entrance cable. It was to this pothead that the surge generator was connected by a resistance, and through it the voltage surges entered the station. It will be noted that the three phases were joined electrically by potential transformers which were connected open-delta, and by the voltage regulator which was *Y*-connected with neutral ungrounded. Each phase had a lightning arrester at the cable pole pothead 1 and at a point on each bus section, 6 and 7; various combinations of these arresters were tried during the tests. The arresters were rated 6,000 volts for use on an ungrounded system. Suitable lightning arresters also were available for connection at the substation pothead and for shunting the regulator series winding.

An analysis of a traveling surge entering the cable from the overhead line shows that, due to the lower surge impedance of the cable, the wave on the line will be reflected with reduced magnitude and reversed polarity. The voltage of the surge entering the cable will be less and the current greater than in the original line surge. The following equations show these effects:

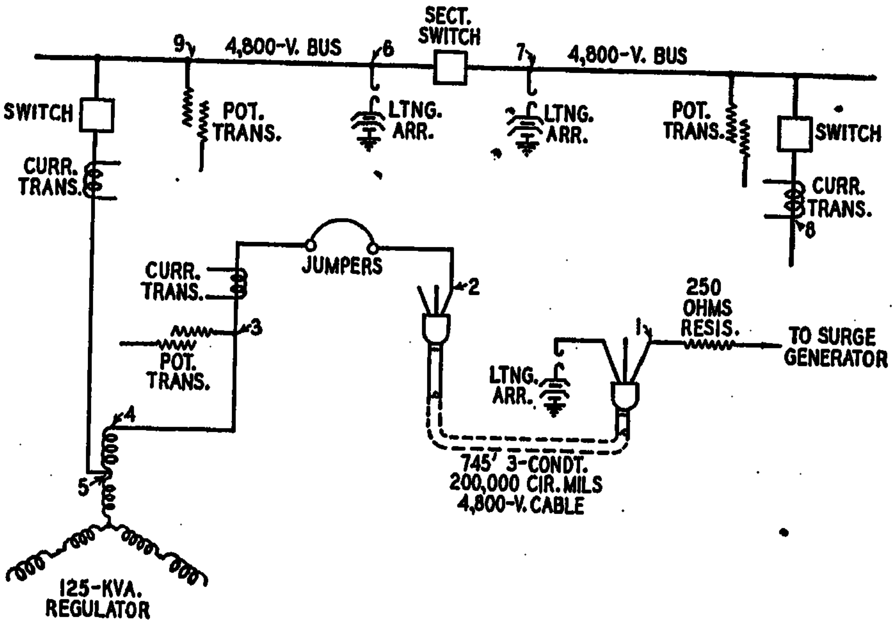

**Fig. 1. Typical circuit layout at Elmdale substation, indicating points at which oscillograms of the surge voltage waves were taken**

$$e = \frac{2Z_c}{Z_c + Z_L} E_L$$

$$i = \frac{e}{Z_c}$$

where

$e$ = voltage of surge in cable
$Z_c$ = surge impedance of cable
$Z_L$ = surge impedance of line
$E_L$ = voltage of surge on line
$i$ = surge current in cable

If the surge generator should be discharged directly into the cable, the current drawn by the arresters would be excessive due to successive reflections of current. Since it was not possible to apply the surge to the cable by means of an overhead line, a resistance was placed in series with the surge generator to limit the current in the cable to a value which would approximate that of a surge entering from an overhead line. In the tests a series resistance of about 250 ohms was used.

Two general types of impulse voltage waves were used. One had a wave front with voltage rise from zero to maximum in approximately one microsecond, while the other, which was secured by connecting 1,360 millihenrys inductance in series with the surge generator, had a wave front with voltage rise to maximum in about 10 microseconds. The wave having the steep front, as nearly as rectangular as possible, was required to show clearly on the oscillogram, reflections of the impulse at the voltage regulator. Tests with surges having the slower wave fronts were also desirable in order to determine the effects of moderate surges of voltage such as may be induced on lines by nearby lightning strokes.

In the preliminary tests it was found that a number of factors which might be considered to be of importance could be neglected. For example, oscillograms taken with various values of resistance connected to the bus to simulate the effects of other circuits indicated that although the surge voltage appearing on the bus decreased as the connected resistances were decreased, the shapes of the impulse voltage waves at points 1 and 2 were unaffected. Therefore most of the tests were made with the station bus open-circuited. It was found also that although in order to simulate connection to an overhead line the two phases which were not connected to the surge generator should be grounded at 1 through a resistance having a value of about 500 ohms the oscillograms did not differ from those taken with these phases open-circuited; consequently most of the tests were made with the latter arrangement. Preliminary voltage-time oscillograms also indicated that the effects of the instrument transformers were slight and that measurements need be taken only at positions 1, 2, and 5. At these three points the oscillograms are quite different because of the effect of the cable pole lightning arresters, the cable itself, and the voltage regulator. Also the voltages induced on the two phases which were not connected to the surge generator were found to be of negligible magnitude, or usually about one-fourth of the voltage on the surged phase. Therefore further measurement of them was omitted.

The impulse voltage tests indicated definitely that only a small amount of energy was drawn from the cable through the series windings of the regulator by the lightning arresters and other equipment connected to the bus, especially for the first part of the wave. In one test a surge of about 25-kv. crest entered the cable and was increased at station pothead 2 to a crest value of about 43 kv. by the partial reflection at the voltage regulator. The positive reflected wave returned to the cable pole end where it caused sufficient voltage rise to break down the lightning arresters located there. These arresters prevented further voltage rise and returned a negative reflected wave to the station end of the cable, reducing the voltage at that point to about 23 kv. Due to the high impedance of the regulator series winding, the rise of surge voltage on the bus was much lower than at the station pothead, and the bus lightning arresters were not able to protect the cable against voltage surges which may enter the substation through it. Additional tests made with the lightning arresters at the cable pole end disconnected also indicated that the lightning arresters on the bus do not provide protection for the cable, as the regulator impedance remained very high for a period sufficient to cause a flashover at the station pothead.

Using the slow-front wave, oscillograms were taken, but these did not show the reflections at the regulator as distinctly as did those for the steep-front wave, because the entering wave does not reach its maximum at the cable pole pothead before the reflection begins to return from the regulator and adds to the voltage of the entering wave. However, if the entrance cable had been long enough to require about 10 microseconds for an impulse to travel back and forth through it, then the reflections would have been just as distinct as for the surge having a one-microsecond front. These oscillograms do show definitely that the surge voltage at the regulator rises to a value greater than that at the cable pole pothead, and the reflections at the regulator are therefore appreciable. Consequently, even with the slow-front wave, the regulator series winding offers considerable impedance and the rise of voltage on the bus is slow.

The tests showed conclusively that the lightning arresters at the cable pole end of the entrance cable only partially limit the rise of voltage at the substation end of the cable. If the front of the incident wave is short and the entrance cable long, approximately double the voltage at the cable pole end will be impressed at the station end for an appreciable time before the cable pole arresters relieve this condition.

By these tests, however, it was definitely proved that the voltage at the station pothead may be limited to a safe value by shunting low voltage arresters across the regulator series winding, thus permitting the bus arresters to help lower the voltage at this point. The rise in voltage on the line side of the regulator then is limited to the sum of the breakdown voltages of these two sets of arresters.

It was also definitely proved that protection could be secured by lightning arresters located at the substation end of the cable. These limit the voltage on the pothead and the regulator, and, in combination with the cable pole and the bus arresters, limit the voltage in the cables within the station and in all of the entrance cables to the drops across the arresters. This method of protection is more desirable than the use of low voltage arresters shunting the regulator series windings, since lightning arresters connected at the station pothead limit the voltage at that point to a somewhat lower value.

# Operating Requirements of the Network Protector

**Rapid extension of the low-voltage a-c.* network in metropolitan areas has required the solution of a number of new problems, among them being the development of a suitable network protector consisting of circuit breaker, relays, etc., to disconnect the feeder from the network at the proper times.**

By
C. W. PICKELLS, JR.
ASSOCIATE A.I.E.E.
N. Y. & Queens Elec. Lt. & Pwr. Co., Flushing, N. Y.

RELAY PROTECTION of the type of low voltage a-c. network installed in the metropolitan area of New York City was designed to give the a-c. network the same reliability of service obtained on a d-c. network. Such reliability was essential if the a-c. network was to be used in areas of high load density where continuity of service is of paramount importance.

Briefly, this type of a-c. network consists of a grid of three-phase four-wire low-voltage mains to which power is supplied at suitable intervals by distribution transformers connected to high voltage feeders. To obtain diversity of supply, adjacent transformers are connected to different high voltage feeders which in turn are supplied by different generator bus sections. Connecting the low voltage side of the transformers to the network are automatic network protectors which are the only means of readily disconnecting the high voltage feeders from the network.

The network protector consists of a three-pole air circuit breaker, a motor or solenoid to close the breaker against the action of springs and gravity, two relays which control the closing and opening of the circuit breaker, and fuses in series with the circuit breaker contacts to give back-up protection.

Many years' experience with the d-c. network, supplemented by test data, indicated that with sufficient power available, faults on the network would burn clear. Thus, the first requirement of the protection scheme was that all sources of power remain connected to the network during network disturbances. The next requirement was for the circuit breaker to open immediately when a fault occurred on the feeder side of the protector, either on the feeder or in a transformer connected to that feeder. In order that a high voltage feeder might be taken out of service with a minimum amount of time and expense it was considered desirable that the protector open on transformer exciting current, as the station operator could then clear a feeder merely by opening the station breaker.

The closing operation also had to meet certain requirements: first, if the transformer is energized while the network is deenergized, the protector must close; second, if the network is energized but the transformer is deenergized, it must remain open; third, when both transformer and network are energized the protector must close when, but only when, the magnitude and phase relation of the transformer voltage with respect to the network voltage is such that after it has closed, power will flow to the network.

### DESIGN OF MASTER RELAY

To meet these requirements a relay usually referred to as the master relay, having three induction type, watt-hour meter elements, was provided. These elements consist of disks mounted on a single shaft between the poles of electromagnets. The connections of the Westinghouse and General Electric master relays are shown schematically in Figs. 1 and 2. Referring to the diagram of the Westinghouse relay, the lower pole of each magnet is magnetized by a potential coil, and the upper poles by either the current coils or the phasing coils. The current coils are connected to current transformers and are energized when the breaker is closed. The phasing coils are connected in parallel with the breaker contact and are energized when the breaker is open. The General Electric relay is similar except that the current coils are also the phasing coils.

The relay operates in the same manner as any directional relay. The interaction of the flux due to current in the potential coil with that due to current in either the current or phasing coils, causes the disks to rotate in one direction if the flow of power is toward the network, and in the opposite direction if the flow is toward the transformer. The relay has one moving contact actuated by the disk shaft, and two stationary contacts. Rotation of the shaft in one direction closes the closing circuit of the protector, and in the opposite direction, the tripping circuit.

When the protector is completely deenergized, the relay is held in the closing position by a spring. Because the potential coil is on the network side of the protector, no magnetic torque will be present when the transformer only is energized; and to cause a protector to close on a dead network, mechanical torque has been provided. When the network is energized but a feeder is deenergized, the protectors associated with it will remain open because current will flow through the phasing circuits to give, in conjunction with the potential coils, maximum opening torque.

---

*Written especially for ELECTRICAL ENGINEERING and based upon a talk presented before the power group of the Institute's New York Section. *Not published in pamphlet form.*

Upon energizing the feeder the voltage across each of the circuit breakers of its associated protector becomes the vector difference between the transformer voltage and that of the network. The torque on the relay depends upon the relation of this so-called phasing voltage to the network voltage. It is desirable that the transformer voltage be somewhat greater in magnitude than the network voltage before the breaker is closed. To impose this limitation upon the operation of the relay, the potential coil flux is lagged by an adjustable shading coil or lag ring so that the potential coils alone exert an opening torque slightly greater than the closing torque of the spring. Before the relay will make its "closing" contacts this excess opening torque must be overcome by the phasing coils. The amount of phasing voltage necessary to close the breaker may be varied by adjusting the shading coils. Practise on the system of the New York and Queens Electric Light and Power Company is to set the relays to close when a phasing voltage of 2 volts exists in phase with the network voltage.

The lamps shown in the phasing circuits and usually referred to as phasing lamps are 15-watt 150-volt tungsten lamps. As tungsten has a high positive temperature coefficient, its resistance will tend to keep the current in the phasing circuit constant regardless of the voltage across it, and the coils can be made sensitive to phasing voltages of widely varying magnitudes.

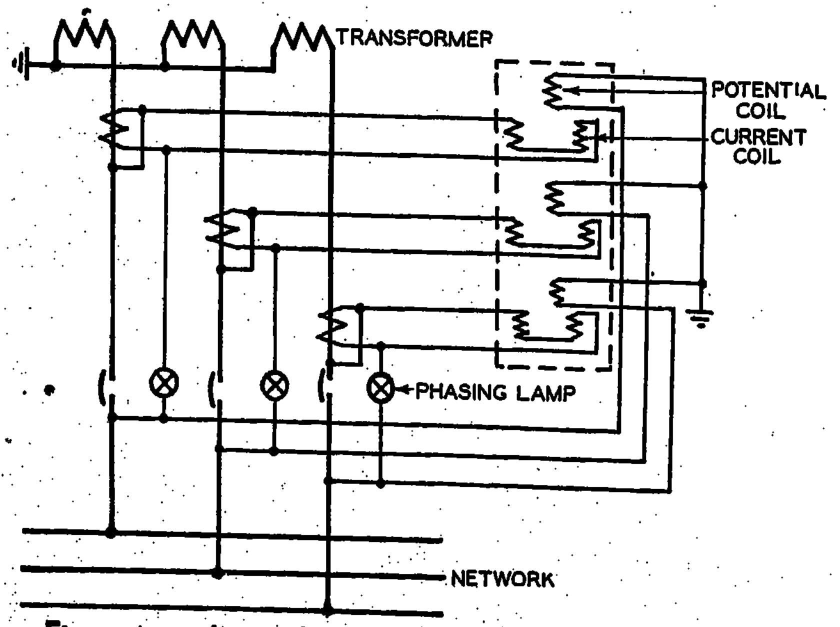
## OPERATING CHARACTERISTICS OF MASTER RELAY

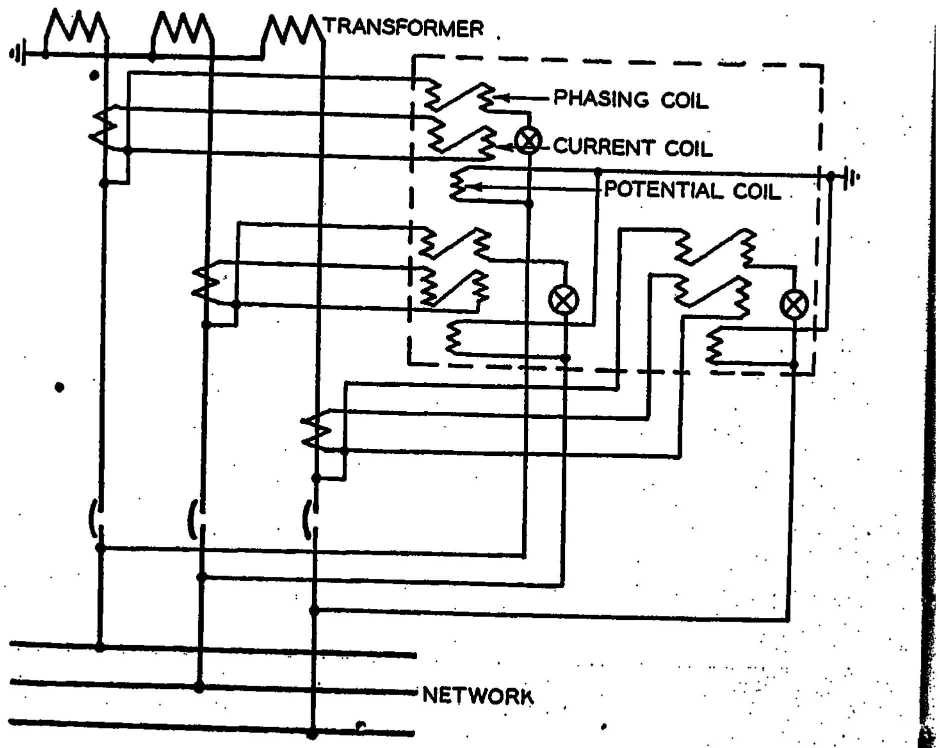
The operating characteristic of a Westinghouse master relay on a 1,600-ampere (submersible rating) protector is shown in Fig. 3. Curve 1 is the locus of line currents varying in magnitude and phase angle referred to the network voltage which will produce a balanced torque on the relay element. If a vector representing current of any given magnitude and phase angle drawn from the origin crosses the curve, that current will cause the relay to close its tripping contacts and the protector will open. If the vector of the current does not cross the curve, the relay will close its closing contacts. It is evident therefore that a current of 30 amperes lagging the network voltage, reversed, by 84 deg. will produce a balanced torque in the relay. As the exciting current of a 500-kva. three-phase transformer with which such a protector is used has an exciting current of approximately 30 amperes at an angle of less than 80 deg., as indicated by the vector $I_E$, the relay will cause the protector to open when exciting current only is flowing. Curve 2, which is curve 1 redrawn to a smaller scale, shows that for currents not exceeding 4,000 amperes the relay acts like the usual watt element, the characteristic being almost a straight horizontal line. When the current exceeds 4,000 amperes, the current transformers saturate and cause the curve to bend rapidly. This saturation protects the relay at high values of current in either direction. When saturation takes place, the ratio of the current transformers not only changes but the phase angle between the primary and secondary currents also changes. The primary current leads the secondary current less and less, with the result that the operating curve bends downward on the right-hand side and upward on the left-hand side. The upward bend improves relay operation on high values of short-circuit current but prevents the relay from operating on high values of charging current. This is indicated on the diagram, where the vector of charging current $I_c$ falls on the closing side of curve 2.

Closing curve 3 is the locus of vectors representing the magnitude and phase relation with respect to the network voltage, of transformer voltages which will produce a balanced torque in the relay. If the vector crosses the closing curve, the protector will be closed; otherwise it will remain open.

## DESIGN OF PHASING RELAY

When the high voltage feeders supplying a network are of different voltage and come from different





**Figs. 1 and 2. Schematic diagram of connections for General Electric master relay (above) and for Westinghouse master relay (right)**

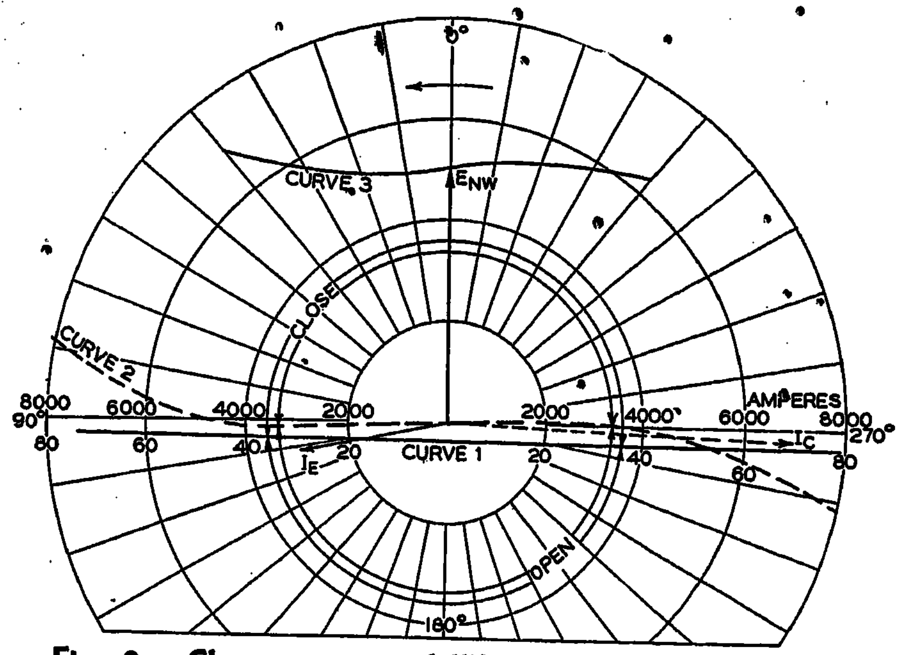


Fig. 3. Characteristics of Westinghouse master relay

For Curve 1 use lower ampere scale; for Curve 2, upper

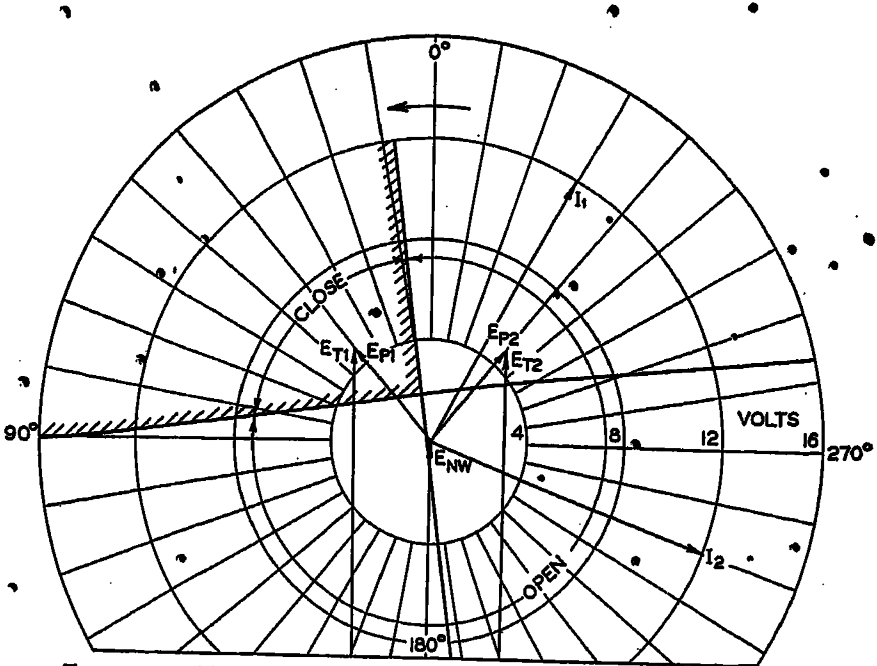

Fig. 4. Closing characteristics of master and phasing relays combined

bus sections of the same generating station, or perhaps from different generating stations, the phase angle between network and transformer voltages with a network protector open may be appreciable. If, during a light load period, the transformer voltage is greater in magnitude than the network voltage but lags it, the phasing voltage may, when the breaker closes, cause power to flow from the network to the feeder. The direction of power flow depends upon the phase angle of the phasing voltage and the impedance angle of the system through which it flows. When such a reversal of power flow occurs, the master relay alternately causes the circuit breaker to open and close, a condition commonly referred to as pumping. Two methods of preventing protectors from pumping are available: one is to add an additional relay called the phasing relay to keep the circuit breaker open when this voltage condition exists; the other is to alter the opening characteristic of the master relay so that it will open the breaker only when the reverse power exceeds a predetermined value. Both methods have been used, each having certain advantages and disadvantages.

The phasing relay is similar to the master relay except that it has a single element and no current coil. The contacts of this relay which controls only the closing of the circuit breaker are in series with the closing contacts of the master relay so that both must be in the closing position before the circuit breaker can close. The constants of the coils in the phasing relay are such that when the phasing voltage is 90 deg. out of phase with the network voltage, maximum torque is produced, the characteristic curve thus being approximately at right angle to the closing curve of the master relay. This relay has an adjustable voltage setting similar to that of the master relay and also an adjustment of the potential circuit constants which permits the curve to be rotated slightly.

## OPERATING CHARACTERISTICS OF PHASING RELAY

The closing curve of the phasing relay combined with that of the master relay is shown in Fig. 4. Only those phasing voltages which extend into the upper left-hand quadrant will cause the relays to close the circuit breaker. Thus, the circuit breaker cannot close when a phasing voltage such as $E_{P2}$ exists and which, with little or no load to be supplied, would cause current $I_2$ to flow and re-open the circuit breaker.

## OPERATING EXPERIENCE

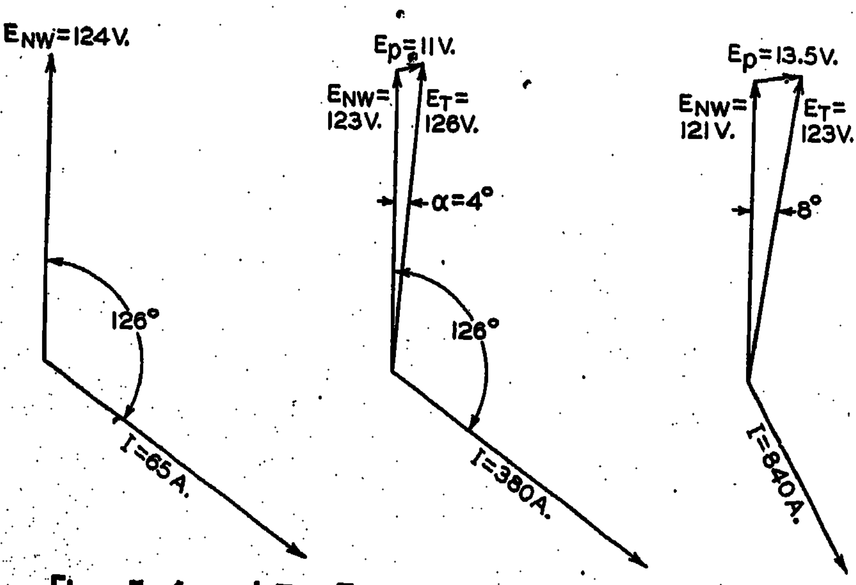
Experience has shown that when phasing relays are necessary to prevent pumping certain protectors may be open at all times except during peak load or may not close at all. When a network is small and the distribution transformers are widely spaced, open protectors are a cause of voltage complaints. If there is an intermittent load on the network occasioned by the starting current of a large motor or electric welding equipment, a voltage dip will occur each time the load comes on, because the transformer capacity is insufficient until the open protectors close. A more serious condition may result if a network is supplied by only two or three feeders, and leading voltage on one feeder keeps the protectors on the others open; for should the first feeder develop a fault, the network will be completely deenergized while the open protectors are closing. The duration of such an interruption of course would be very short; but still it would be sufficient to shut down synchronous machinery or any apparatus controlled by relays operating on loss of voltage. Furthermore, the number of protector operations would be increased. This is an objectionable feature from the standpoint of maintenance and public relations.

## PROVISION FOR NON-SENSITIVE RELAY SETTINGS

As a result of experience and investigation the protectors now being purchased by the New York and Queens Electric Light and Power Company have provision for altering the relay opening characteristic so that the relays may be given reverse current settings up to 20 per cent of the protector rating. The

Westinghouse company provides a spring restraint on their master relay which will give a reverse setting from 0 to 25 amperes. From 25 to 320 amperes the setting is obtained by means of the shunt reactor method. This method consists of connecting a reactor in parallel with each current coil of the relay so that less than 10 per cent of the current in the secondaries of the current transformers flows through the relay. Thus a relay set to trip on 25 amperes in-phase component of reverse current without the reactors, will trip on approximately 250 amperes with the reactors. An additional feature is a set of contacts in each reactor circuit which open on overcurrent of approximately 150 per cent of the protector rating; for example, when the current on a 1,600-ampere protector exceeds 2,000 amperes, these contacts open and the relay setting drops to that of the spring adjustment. The combination of shunt reactors and cut-outs makes the relay insensitive to all reversals of power obtained under normal conditions, but sensitive to feeder fault conditions.

The General Electric master relay also has a spring restraint which will provide settings between 0 and 25 amperes. To obtain settings above 25 amperes a voltage-restraining element is added. This element, which has two potential circuits, exerts a closing torque upon the bottom disk of the relay. The circuits are energized from the delta side of a $Y$-delta transformer. The torque exerted by this element is proportional to the area of the delta and as the area of the delta decreases rapidly for single-phase or phase-to-ground faults the restraint or setting decreases likewise. When unbalanced faults occur, one of the watt elements has to provide all or most of the opening torque, and unless the restraint is reduced in some fashion, abnormally high current is required to cause the relay to open the circuit breaker. To further assist the relay on unbalanced faults, the potential coils of the watt elements are connected phase-to-phase instead of phase-to-ground when voltage restraint is applied. The phase-to-phase voltages are sustained nearer their normal value and so are better able to produce an opening torque than are the phase-to-ground voltages.



**Figs. 5, 6, and 7. Test data of reverse power flow**

A back-feed condition caused by a 116-ton punch press driven by a 75-hp. induction motor is shown in Fig. 5 (left). The down stroke of the press drives the motor above synchronous speed and when there is little additional load in the plant, power is supplied to the feeder as indicated; this back-feed caused the protectors to open and the protector relay had to be given a setting of 150 amperes. In Fig. 6 (middle) is shown a back-feed condition due to a phase angle difference between two 4,000-volt feeders supplied by different generating stations. The relays at this location could not be set high enough to carry the back-feed current so a phasing relay was used to prevent pumping. An extreme case, shown in Fig. 7 (right) resulted when two transformers in the same vault were connected to 26.4-kv. feeders from different generating stations, the transformers being lightly loaded during the period of heavy feeder load. The use of a phasing relay to hold the protector open was the only solution

## LIMITATIONS

The objection to the use of non-sensitive settings is that protectors will not open when the station feeder breaker is opened or assuming the network transformers to be connected delta-$Y$, when a fault occurs between one conductor of the feeder and ground. If the feeder charging current is small or if it is so divided among the transformers connected to the feeder that the amount through each is small, the only disadvantage is the necessity of manually opening the closed protectors. However, if charging current of 3,000 amperes or more were permitted to flow through one transformer, the voltage of the network in the vicinity of the transformer might be raised to a value which would endanger utilization equipment.

The extent to which the network voltage might be raised would depend upon the impedance of the network as well as upon the magnitude and phase angle of the current. If the charging current of a 26.4-kv. feeder, 5 miles or more in length, were supplied by one transformer, the voltage probably would rise 20 per cent, and for certain values of current and impedance might rise 50 per cent. In order that such a condition shall not exist it is the practise in the Borough of Queens to reduce the charging current of each feeder to a safe value by connecting shunt reactors. The lagging current drawn by these reactors added to the charging current gives a resultant current of a magnitude and phase angle which will not cause an objectionable voltage rise.

Experience on this system has been that protectors on 26.4-kv. transformers can be operated with sensitive relays if care is taken in the choice of feeders supplying adjacent transformers. It is intended to limit each protector to one operation a day, and of course to keep all protectors closed which if open would cause the network voltage to drop below the allowable minimum. At the present time only one protector of a total of 150 associated with 26.4-kv. transformers requires a non-sensitive setting.

The use on 26.4-kv. feeders of shunt reactors and sensitive relay settings has resulted in correct relay operation both when feeders are opened at the stations and when phase-to-ground faults occur. However, on lower voltage feeders non-sensitive settings often are required making it necessary to open these protectors manually before a feeder can be cleared for construction work. This means considerable delay and additional expense which should be avoided if possible. This limitation of the present network protection and a desire to simplify the relays have caused considerable thought to be given to new protective schemes.

### FUSES

The network protector fuses which are of the link type and of either copper or alloy, provide back-up protection in case the protector fails to open the circuit in the normal manner when a fault occurs on the feeder side of the protector. They provide protection also to the network transformer when a fault occurs on the network side of the protector which because of its proximity to the transformer, its duration, or both, may result in the transformer becoming overloaded beyond its thermal capacity.

The minimum blowing value of these fuses is approximately three times the full load current of the transformers. This value is less than the value of short-circuit current which will flow into a fault on the transformer side of the protector from an extended network having ample transformer capacity; but this minimum blowing value may not be less than the value of short-circuit current if the transformers are few and widely spaced. However, to use a fuse of lower minimum blowing value would result in unnecessary blowing of fuses with network faults.

Although the blowing of fuses due to network faults has been very infrequent, a solid fault near a transformer which does not clear immediately will cause the fuses to blow. In an area of high load density with transformers a block apart a fault on the network may cause the fuses in three protectors to blow. The disconnecting of this amount of transformer capacity from the network in one locality would result in low voltage.

The use of plain link fuses for back-up protection has certain disadvantages. If the minimum blowing value is low enough to insure opening the circuit for lower values of short-circuit current flowing toward the transformer, they will blow so rapidly on the high values that this blowing may take place before the protector circuit breaker can open. To protect the transformer against overheating when supplying current to network faults, the fuses should have a current-time curve similar to but slightly below the maximum safe current-time curve of the transformer. Because of the pronounced difference in their thermal capacities the curve of the fuse has a steep slope whereas the curve of the transformer has a gradual slope. Thus a fuse which will blow at low values of current only when the transformer has reached its maximum safe temperature, will blow too soon at higher values, and probably unnecessarily. A third disadvantage is the amount of heat generated by the fuses. Elimination of this heat in protectors enclosed in submersible boxes should permit an increase in their current rating.

In place of link fuses there is need for a back-up circuit breaker of small dimensions and low cost which can be given a definite time, overcurrent setting for current flowing from the network, and an inverse time, overcurrent setting for current flowing toward the network. The inverse current-time curve should parallel closely the maximum safe overcurrent-time curve of a distribution transformer.

# Molybdenum—

## *The Metal That Talks*

DISCOVERED BY SCHEELE in 1778 in the form of an oxid, molybdenum was first separated as a metal by Hjelm in 1782. Now it is produced commercially by hydrogen reduction of the oxid, pure oxid being obtained from ammonium molybdate. The resulting metallic powder is sintered, forged, and rolled into desired shapes. When pure, molybdenum is soft, white, and ductile.

During the last 35 years a great deal of research work was done in Europe, Japan, and the United States; many characteristics of the metal were developed. It did not come into prominence, however, until the World War when it was used extensively as an alloying element in light armor plate, helmets, and Liberty engines, because of the great increase in strength and toughness imparted by it to steel.

Even in war time, however, its application was limited, due to uncertainty of supply and high cost. In the last few years large deposits of ore have been discovered in the United States; there are deposits of varying richness in many parts of the world, but the largest and richest known are in this country. Commercial deposits are found ranging in richness from 0.5 per cent up to 8 or 10 per cent molybdenum sulphide ($MoS_2$). After grinding and flotation, the ore is concentrated to about 80 per cent $MoS_2$; from these concentrates commercial products are made. Rapid lowering of cost by increased production has resulted in a large portion of the world's requirements being supplied from American mines. Hence in times of stress this important element could not be shut off from this country as could some alloying elements used in steel.

It has been said that, excepting carbon, molybdenum is the most potent alloying element added to steel. It can be substituted for tungsten in ratio of 1 for 2. In quantities generally used in steel, molybdenum for the most part goes into solution with the iron, although it forms a double carbid when present in amounts of more than 1 per cent or when considerable quantities of chrome or manganese are present. It also is probable that when cooled through the critical range, a definite compound of molybdenum and iron is formed. Used in amounts as small as 0.1 per cent or 2 lb. to the ton, it has shown marked tendencies in resisting corrosion. In quantities up to 10 per cent it offers a possible substitute for tungsten high speed tool steels.

Thin-walled, high-strength, chromium-molybdenum steel tubing has made modern high speed airplanes possible, and no substitute has been found for highly stressed members in the fuselage. Such tubing combines the unusual advantages of high

---

From *Research Narratives*, Jan. 15, 1932, published by the Engineering Foundation, 29 West 39th St., New York, N. Y. Based upon information supplied by W. H. Phillips, metallurgist, vice-president, Molybdenum Corporation of America, Pittsburgh, Pa.

strength without complex heat treatment, easy weldability, and no appreciable loss of desirable properties in welded joints; it enables designers to increase strength with no increase in weight.

The pure metal is used extensively in the incandescent and radio bulb industry. According to a booklet, "Rare Metals" (Fansteel Products Company, North Chicago, Illinois): "To say that the air or ether carries the radio broadcast wave is true, but it's a certain metal sealed tightly in tubes which puts the wave on the air, and, then in different tubes, recaptures it to be turned back into music or words. This metal is molybdenum—the metal that talks." Literally thousands of miles of molybdenum wire, drawn through diamond dies, have been used in the radio industry.

But that is not all, for, in the form of salts and oxids, this versatile metal is used in the chemical and dye industries. Thus do we find modern industry, engineering, and research making a place for a material known for a century and a half, but little used until within the last few years.

# Engineering Features of Gas Filled Tubes

**Introduction of gas or vapor into electron tubes has increased greatly the field of application of these devices. Hot-cathode mercury vapor tubes of this type are especially adapted to rectifier and inverter service. Fundamentals, design features, and operating characteristics of these tubes are given in this article.**

DURING the past few years vacuum tubes have found an ever enlarging field in industrial applications. This has been brought about primarily by vast improvements in the design of the tubes themselves. In addition, the more recent gas filled tube provides the application engineer with a tool even more suited to his needs. Some of the outstanding engineering features of gas filled electron tubes are as follows:

1. The tubes are static devices[1] (For numbered references see bibliography.), the complete functions of which are performed through the movement of electrons and ions.

2. Efficiency in controlling or converting power is high; tube efficiency ranges from 95 to over 99 per cent.

ıtrol is flexible and the power required for control is small.

4. Speed of operation as a relay is extremely fast, and in addition the tube may function either cycle by cycle or intermittently without the wear that accompanies the operation of mechanical devices.

5. Noise and vibration are entirely absent.

The name "Phanotron" has been applied by the General Electric Company to gas or vapor filled electron tubes, and in that company's practise the name has become associated with the two-element or simple rectifying tube. Tubes of this type in which the starting of the conduction period is controlled electrostatically by the action of one or more grids, have been termed "Thyratron" tubes, the name being coined from the Greek "thyra-," meaning "a door," and "-tron," meaning "a device."

## FUNDAMENTALS OF THEORY AND OPERATION

Theory and operation of vacuum and gas filled tubes have been treated previously.[2,3,4] Briefly, the theory in the case of a high-vacuum tube is that electrons can be drawn from the cathode to the anode when the potential of the anode is above that of the cathode. These electrons in passing from cathode to anode form a charged cloud which gives the so-called space-charge voltage drop that depends upon electrode spacing, current drawn, and several other factors; it may vary in magnitude from a few volts to several thousand. In the gas filled tube, electrons are drawn from the cathode as before, but collide with gas molecules in passing to the anode thereby causing ionization which neutralizes the space-charge. Color and appearance of the glow produced is characteristic of the gas and its pressure. The magnitude of the arc drop voltage is practically independent of the current drawn, and for thermionic cathodes within the limits of the tube design is of the order of from 5 to 25 volts. The voltage drop depends upon the available cathode emission, nature and pressure of the gas, and the design and spacing of the tube elements. When the potential of the anode becomes negative with respect to that of the cathode, conduction ceases.

Simple gas filled rectifier tubes consist essentially of two elements: an anode and a cathode, surrounded by an evacuated container into which a partial atmosphere of an inert gas or vapor has been introduced. The cathode may be of the cold, thermionic (hot) or mercury pool type. Any of the

---

y full text of "Engineering Features of Phanotron Tubes" presented ..E.E. North Eastern District meeting, Providence, R. I., May 4–7, *i published in pamphlet form.*

inert gases, such as argon, neon, or helium, mercury vapor, or a combination of these elements may be used. In the more common tubes, the cathode is of the thermionic type, and the vapor pressure is supplied by a small quantity of mercury. During operation nearly all of the current is carried by electrons from the cathode while the positive ions serve mainly to neutralize the space-charge voltage drop.

In the three-element tube a control grid has been added which interposes an electrostatic screen between the anode and cathode as in the high-vacuum tube. When a direct potential is applied to the anode of a high-vacuum tube, its grid gives a continuous, uniform control of the anode current. In the gas filled tube the grid as usually operated controls only the starting of the current and thereafter exerts no appreciable influence upon the current flow. Grid control can be reestablished, however, by removing, reducing to zero, or reversing the polarity of the anode voltage for a period sufficiently long to allow the tube to deionize. If an alternating potential is applied to the anode, the grid has opportunity to regain control during the negative portion of each cycle and to delay the starting of the anode current for as long a period in the positive portion of the subsequent cycle or cycles as desired. It is possible thus to control the average current flowing through the tube.

Control of the average anode current may be obtained by several methods. The critical grid voltage at which conduction takes place when an alternating potential is applied to the anode is somewhat in the form of a sinusoidal wave in phase opposition to the anode voltage. (See Fig. 1.) When a direct potential is used for grid control, the average output varies from zero to half voltage in one step and is then uniform from half to full voltage. If, however, the grid as well as the anode is supplied with an alternating potential of the same frequency, and further, if the phase relations between the grid and anode voltages can be varied, complete and uniform control of the average voltage output may be obtained. In Fig. 1 is shown the effect on the output (shaded portion) as the grid potential is successively advanced from the nearly out-of-phase position (*A*) to the in-phase position (*C*). The output may be controlled also by varying the magnitude of the grid potential and by combinations of the d-c. bias, phase, and magnitude methods.

## TUBE DESIGN AND OPERATING CHARACTERISTICS

Certain factors of tube design warrant special attention. The type and form of the cathode and anode, the operating pressure of the gas or vapor and the type of grid control require a close degree of coordination in order to insure satisfactory performance.

*Cathodes.* As already mentioned, three general types of cathodes are in use, namely: the cold, the mercury pool, and the hot or thermionic types. In the cold cathode, electrons are drawn from the cold surface of an electrode through the action of an intense electrostatic field. Cold cathode tubes have a relatively high voltage drop and a comparatively small current carrying capacity.

In the mercury pool tube a cathode spot is established and maintained on the surface of the mercury by auxiliary electrodes. The pool cathode is well known through its use in mercury arc rectifiers[5] and has ability to supply high peak currents. An adequate cooling surface must be provided to condense the mercury evaporated by the cathode spot. Since the tube elements must be shielded from the blast of evaporating mercury and spray, the arc drop voltage usually is higher than that of tubes with equivalent thermionic cathodes.

Hot or thermionic cathodes furnish electrons through the heating of a metal that is an active thermionic emitter or that has been coated with an electron emitting material. The hot cathode used in the majority of gas filled tubes is of the Wehnelt or oxide coated form because of its efficiency, durability, and reliability of operation.

Oxide coated cathodes may be divided into two general types: (1) the filament or directly heated type, and (2) the indirectly heated type. Filament cathodes are used in some of the tubes where rapid heating is essential, and may be shielded. In indirectly heated cathodes, the heating element is

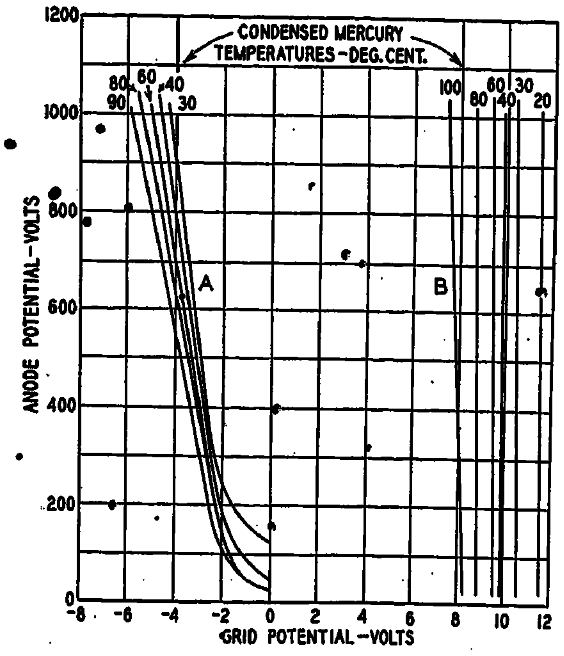

**Fig. 3.** Voltages at which conduction starts for two typical three-element mercury-vapor tubes with (A) negative control and (B) positive control

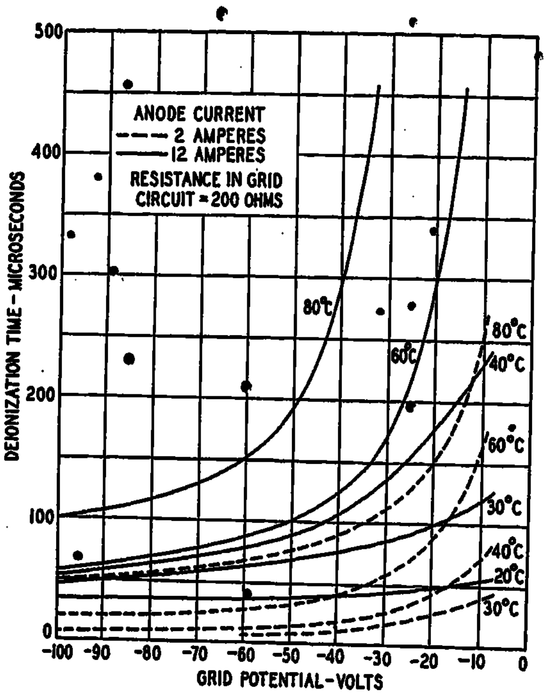

**Fig. 4.** Deionization time at different condensed mercury temperatures of a three-element mercury-vapor tube designed primarily for inverter purposes

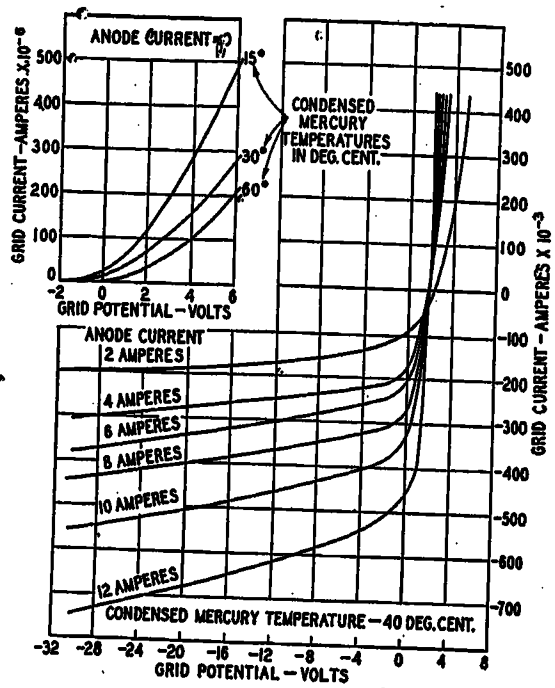

**Fig. 5.** Grid current vs. grid voltage for several values of anode current for same tube as in Fig. 4

commonly a separate tungsten heater which through radiation or conduction, supplies its energy to the emitting surface.

Heat shielding and concentration of the cathode in small space are made possible in gas filled tubes through ionization of the gas which neutralizes any space-charge and permits electrons to be drawn from crevices and made to emerge from comparatively small holes in the cathode shields. This would be impracticable in high-vacuum tubes. Time required for a cathode to reach operating temperature is a function of the ratio of cathode mass to heating power; consequently, the heating time is a minimum in unshielded cathodes and increases with shielding. In general, the more efficient the cathode, the longer is the heating time. Potential at which the cathode heating power is supplied is held below the ionization potential of the gas (10.4 volts for mercury vapor).

*Gas Pressure.* Pressure of the gas governs the temperature limits of operation in any gas filled tube. In mercury vapor tubes, the pressure is determined by the temperature of the coldest part of the tube; mercury condenses at this point and a measurement of the temperature gives an indication of the pressure in the tube. With excessive gas pressure, conduction in the reverse direction or arc-back may occur; also under these conditions a three-element tube may lose control. If the pressure is too low, the arc voltage rises above the critical value[2] at which cathode disintegration begins. In addition, low vapor pressure seriously reduces the ability of the tube to start conducting heavy currents; under such conditions, sputtering of the cathode and sometimes arc-back may occur. In general there exists a definite range of pressure for satisfactory operation. For most tubes this range of pressure corresponds to ambient air temperature of from 20 to 50 deg. cent. Temperature rise of the condensing mercury above ambient varies from approximately 15 to 50 deg. cent., depending upon the tube design. These conditions are illustrated in Fig. 2.

Control characteristics of tubes in which an inert fixed gas is used are nearly independent of ambient temperature changes. This characteristic is of particular advantage where large ambient temperature variations are encountered and where constancy of control is desired. Pressure limits are determined by loss of control and reverse current conduction for the upper limit, and by gas "clean-up" for the lower. However, the operating ranges of voltage and current are far less than those of similar mercury vapor tubes.

*Control Characteristics.* Two classifications of three-element tubes are made with regard to the control characteristics—negative and positive. A negative control tube is one the critical grid voltage of which is negative with respect to the cathode over most of the operating range. Since conduction starts when the grid is negative, very little grid current is drawn before discharge. A positive control tube is one in which the critical grid voltage is positive over most of the operating range. In this type the electrostatic field of the anode is relatively weak at the cathode; consequently, it is necessary to drive the grid positive in order to establish conduction. It may even be necessary first to produce ionization between cathode and grid before anode conduction occurs. Control curves for the two types are shown in Fig. 3.

*Ionization and Deionization Time.* The time required to establish conduction, sometimes called "ionization time," varies from less than 1 microsec. in two-element tubes and some of the negative control three-element tubes to several microseconds in the positive tubes; it varies with the vapor pressure, tube design, and grid excitation.

Time required to regain control, or the "deionization time," varies with the anode current, vapor pressure, grid excitation, and anode voltage change.[4] Length of the deionization time may vary according to tube design from a few microseconds to approximately 1,000 microsec. This factor is of little importance in ordinary rectifiers or in controlled rectifiers utilizing three-element tubes when operating at the usual distribution frequencies. Commutation or current transfer from one tube to another is natural and sufficient time exists to regain grid control. In inverters, however, commutation is forced and the available time to regain grid control is short; consequently, tubes having high speed deionization qualities are essential. Deionization time for one type of three-element tube is given in Fig. 4.

Grid current before and after ionization occurs is shown in Fig. 5. These curves illustrate the need of carefully designed grid circuits in order that the grid currents which flow when the gas is ionized do not unbalance the control circuit.

### RATINGS OF GAS FILLED TUBES

Certain ratings used in describing gas filled tubes are peculiar to these tubes; some of the more important of these are:

1. Maximum peak inverse voltage.

This is a rating applying to both two- and three-element tubes; it represents the maximum voltage that should be applied between anode and cathode of a tube during operation when the anode is negative with respect to the cathode. Under normal conditions this voltage is simply the crest of the total transformer voltage. These theoretical values may be exceeded several fold under abnormal conditions due to line surges or other disturbances. Determination of the actual peak inverse voltage is necessary in such cases; this may be done conveniently by means of a sphere gap or cathode ray oscillograph. Theoretical peak inverse voltages for several commonly used rectifier circuits are shown in Fig. 6.

2. Maximum peak forward voltage.

This rating applies to three-element tubes only; it represents the maximum positive anode potential that the grid will control when supplied with suitable voltage. In general, the magnitude is the same as that of the maximum peak inverse voltage.

3. Maximum peak anode current.

This is an indication of the available cathode emission, and, for a given life and service, represents the highest instantaneous current a tube will conduct in the normal direction of current flow. The length of time a tube will withstand a given instantaneous current or the frequency with which it will withstand an instantaneous current of given duration depends upon the ability of the tube to dissipate heat.

4. Maximum average anode current.

This is a rating based upon tube heating and represents the highest average current that can be carried continuously. Equilibrium temperature of the tube elements is reached quickly for a given load because the elements in general have a small mass; consequently, in addition to the average current rating the integration period must be stated. Losses in the arc vary directly with the average current rather than the value, since the arc drop is practically constant and independent of the current.

5. Maximum surge current.

Under abnormal operating conditions, such as occur when a rectifier is short-circuited, the anode current becomes limited almost entirely by the transformer and line impedance. The short-circuit impedance of power transformers usually is of the order of from 5 to 10 per cent of the rated impedance; consequently, the short-circuit current may reach values of from ten to twenty times normal. In order to indicate the available transient emission of the cathode a "maximum surge current" rating sometimes is given. Individual tubes may fail under short-circuit conditions, but experience indicates that with proper circuit and tube coordination, the majority will stand a great deal of punishment.

6. Maximum peak and maximum average grid currents.

These represent the grid current ratings; usually they have the same integration period as that of the anode current rating.

$= 2.34\ E_{r.m.s.}$
$E_{inverse} = 1.047\ E_{avg.}$

**Fig. 6. Typical rectifier circuits and voltage relations for two-element tubes**

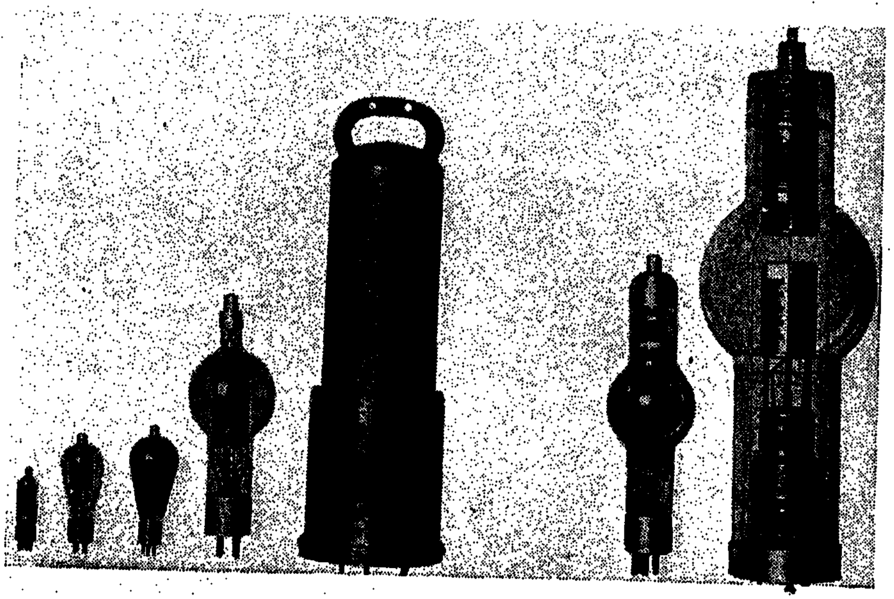

**Fig. 7. A group of three-element vapor-filled tubes for control, power rectifier, and inverter purposes**

The group of five tubes on the left have maximum peak anode current ratings of from 0.5 ampere for the smallest to 600 amperes for the large metal-clad tube, peak forward and inverse voltage ratings range from 1,000 to 3,500 volts. The two tubes on the right have peak ratings of 15,000 volts and are capable of conducting peak anode currents of 75 and 450 amperes, respectively. Two-element tubes of similar dimensions and ratings also have been developed

Fundamentally, the application of these tubes may be divided into two classes: (1) that of the rectifier in converting alternating current into direct current with or without voltage control; and (2) that of the inverter[6] in changing direct current into alternating current.

## RECTIFIER APPLICATION

A typical circuit for a bi-phase, half-wave rectifier with voltage control is shown in Fig. 8. (The term "bi-phase" is a part of a proposed circuit nomenclature for rectifiers.) Current and voltage relations in this circuit are shown in Figs. 9, 10, and 11, for loads approximating resistance, inductance and capacitance operation, respectively. In each case the oscillograph elements have traced the output and anode voltages, and the anode current of one tube.

Oscillogram *A* of Fig. 9 shows voltage and current relations for the rectifier with a resistance load and operating at full output; that is, the grid voltage is in phase with the anode voltage. In oscillogram *B* the grid voltage has been retarded approximately 90 deg. so that anode conduction begins at about the peak of the anode voltage wave. The sudden doubling of the inverse voltage is due to the start of conduction in the opposite tube. With no current flow in either tube, the cathodes assume the potential of the transformer mid point; consequently, the inverse voltage is only half of the transformer voltage. When conduction is established through one tube, the total transformer voltage (less the tube voltage drop) appears across the other.

Effect of introducing an inductance as a filter in the output circuit of the rectifier of Fig. 8 is shown in Fig. 10. In oscillogram *A* the grid voltage is in phase with the anode voltage and the relations correspond to those of simple two-element rectifier tubes. Oscillogram *B* shows the effect of retarding the grid voltage. In the case of a bi-phase rectifier operating with an inductive load, it is possible theoretically to control completely the voltage output with a total grid phase shift of 90 deg. An inductance is essentially a constant current device which stores or releases energy as the voltage applied to it rises or falls. Consequently if the anodes are made conducting by the grids at the peaks of the applied voltage waves or later, anode current will flow in each tube until transferred to the other, or for 180 deg. During half of this time, however, the anode voltage will have reversed its polarity and the net output is zero. The energy relations correspond to those of a circuit with a 90 deg. lagging power factor. The effect of leakage reactance in the transformer upon the commutation or transfer of current from one tube to the other also is shown.

Commutation in a rectifier is a natural process, since the anode voltage of the tube that is ceasing to conduct is falling and that of the incoming tube is rising. During the period when both tubes are conducting, a short-circuit current begins to flow in the reverse direction through the tube that is ceasing to conduct. When the peak of the short-circuit current reaches the value of the previous anode current, conduction ceases.[5]

resistance of gas filled tubes. With capacitance operation the maximum peak anode current may be unintentionally exceeded while operating at less than the average current rating.

## INVERTER APPLICATION

When applied to inverter operation the function of the three-element tube is essentially that of a switch for changing the unidirectional flow of direct current to alternate sections of transformer windings. In inverters some form of energy storage is necessary not only to commutate the flow of current from one winding to another, but also to aid in deionizing the tube and so establish grid control.

A simple single-phase inverter circuit is shown in Fig. 12. In operation the grid of tube *A*, for example, is made sufficiently positive to establish conduction, while the grid of tube *B* is held sufficiently negative to maintain control. Current then flows from the d-c. source through the inductance and one half of the transformer winding, completing the circuit through tube *A*. Commutating condenser *C* becomes charged negatively at tube *B* and positively at tube *A*, to a potential the value of which is nearly twice that of the d-c. line. At the end of the cycle the polarity of the grids is reversed and tube *B* is made conducting. Current that previously had been flowing through tube *A* is diverted to the condenser, and as conduction ceases the anode of tube *A* is driven negative, the grid thereby gaining control. Meanwhile, current flow is transferred to tube *B* and its half of the transformer winding; commutation of the tube currents is then complete. The condenser is charged again but with opposite polarity for repeating the switching operations. On the output side of the transformer the tube voltage waves combine to produce an alternating voltage that by proper circuit constants can be made practically sinusoidal.

Oscillograms of Fig. 12 were taken with the inverter operating at 60 cycles and supplying a resistance load. The relation of the condenser current to the anode current during the commutating period is shown clearly. During the commutation period in order that the grid may gain control, all ions within the tubes in the space between anode and grid must diffuse to the elements before the anode voltage becomes positive. The length of this period is extremely short in comparison to that available in a controlled rectifier. Consequently, the deionization time of the tubes for this service must be short, and in addition, both grid and anode must be designed to withstand severe ion bombardment.

In the present state of development the gas or vapor filled tube has increased manyfold the current carrying capacity of the electron tube. As the field of usefulness increases, even larger tubes and tubes with greater sensitivity of control may well be developed.

# Labor and Engineering Progress

**Application of engineering methods, training, and skill to the social, political, and industrial problems of the present day would contribute in a valuable way toward satisfactory stabilization. This is the tenth article in The Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"**

By
WILLIAM GREEN

President, American Federation of Labor

TO SCIENTIFIC RESEARCH and to the engineers of this country we owe our notable progress in the technical side of industry. Mechanical power is replacing physical power. Workers are controlling machine tools that produce at a rate that would have staggered the giants of the legendary ages. Giant cranes, tractors, steam shovels, double crank presses, conveyers, cash registers, calculating machines, dynamos, and many other devices revolutionized industrial processes. Engineers are largely responsible for marvelous machine tools and for continued experimentation in chemical processes—to put to the service of mankind the last word in science.

The past ten years have brought unusual rapidity in technical progress. This is apparent from comparing the increase in productivity between 1919 and 1929 with that from 1899 to 1919: 54 as against 26 per cent. To state this in another way, this increase in productivity shows up sharply when translated into hours. Work that kept a workman busy 59 hours a week in 1899 was done in 47 hours in 1919; work which was done in a 52 hour week in 1919 was done in 34 hours in 1929. These increases in workers' productivity have brought a steady decrease in the unit costs of production.

In addition to improved tools and processes, the principles of mass production have made available to millions many products which formerly were luxuries within the reach only of those within the higher income brackets. The wage earner with an automobile has access to wider opportunities for work and choice in adjusting the details of living than the wage earner limited by his own traveling capacity. Life and work are now conditioned by control of horsepower. The radio brings him control over wider areas of information and contacts with the personalities and lives of others. Facilities for sanitation and cleanliness give wage earners of today comforts that not even royalty enjoyed two centuries ago.

On the employment side of the ledger, technical progress has brought exceedingly difficult problems to workers and industry. Our term *technological unemployment* expresses an experience that often has made science seem the enemy of wage earners. But this is because science has been used without taking into consideration the fact that wage earners have an equity in their jobs. How to make quantities has been learned, but not how to get them to the people who can use them, or how to distribute equitably the returns from joint products. Present attempts direct these modern currents through the old channels developed in the days of hand production.

Wage earners make a very important investment in industry. They put in the time and labor necessary to turn out the products of the industry; they put in their creative capacity, their intelligence, their work lives. The time has been reached when securities for these non-material investments must be given consideration commensurate with that for capital investments. Merely speeding up the industrial machine is not an unmixed good unless engineers realize that these changes profoundly affect human lives, and plan to make the influence constructive.

When undertakings are going to affect one or more groups, the only way to make sure that all those having legitimate interests are safeguarded is to provide for collective consideration and counsel. This is in accord with the engineering practise of finding and applying facts. This field of facts of human progress affords the ultimate tests of the value of engineering progress. Failure to consider the consequences of policies and changes upon interrelated interests results in perplexing problems that impede progress and precipitate strife.

World-wide economic distress has resulted from failure to recognize interdependence of national interest. Within our country is found failure to balance interests and progress. Custom has established certain priorities for material interests that have worked for unequal distribution of wealth and income and absence of security for many. Wage earners belong to the groups denied priorities in security.

It has been pointed out that, because all interests are interrelated, we must work out principles of balance; increasing output against capacity to buy; increasing productivity against increasing leisure, technical progress against the available supply of labor, output against the incomes of buyers, volume of business against available credit, etc. Sustained business prosperity can be attained only through an understanding and application of the principles of balance. The welfare of mankind can be advanced safely in this complicated age only when the principles of balance between forces which work for progress and retrogression are understood.

To define its status and well-being, Labor has outlined the following Labor program:

1. Organization of all functional groups to advance their group interests, and collective conferences and agreements to promote progress for all, in which Labor shall participate.
2. Reduction of weekly work hours as productivity increases.
3. Wage increases to raise consumer credit as output increases.
4. Partnership of labor in the production undertaking, carrying job, and income security.

Application of these principles would give Labor and all other groups a fair chance to advance their interests in individual establishments, but this is not enough. The industries of a nation are dependent upon each group for prosperity or depression. Therefore, there must be nation-wide planning by industries and collective discussion and agreement for the nation, together with consideration of the world market.

To these larger problems which include the intangible as well as the technical forces with which engineers are familiar, the engineers of the country can make valuable contributions. It is hoped that engineers will feel a responsibility for carrying their methods of work into the larger field.

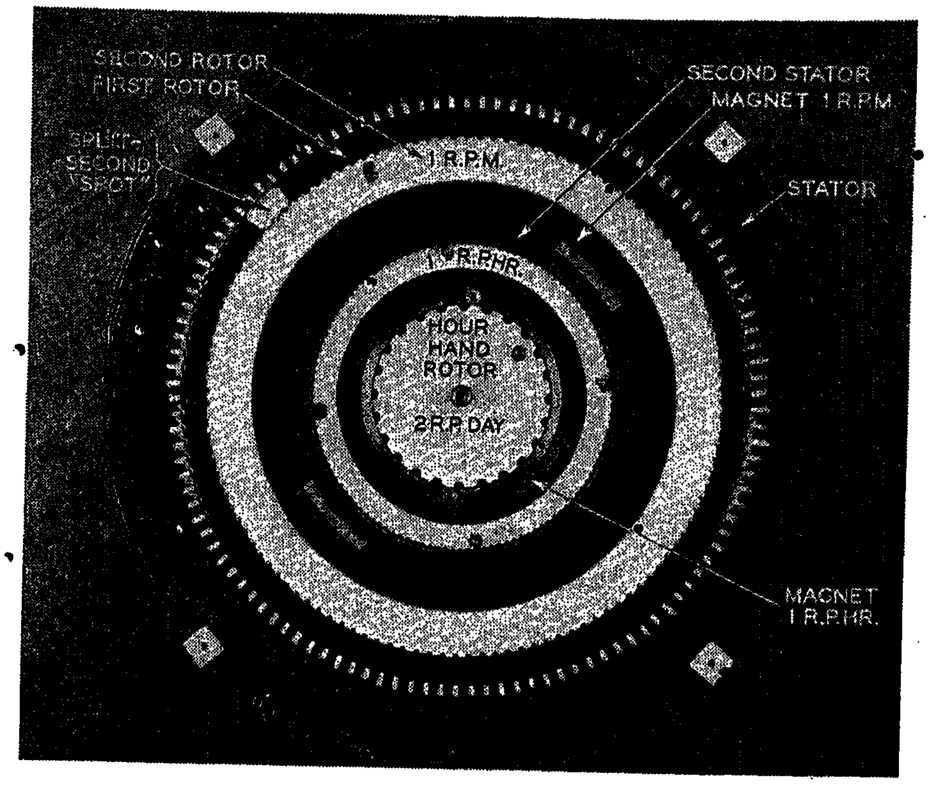
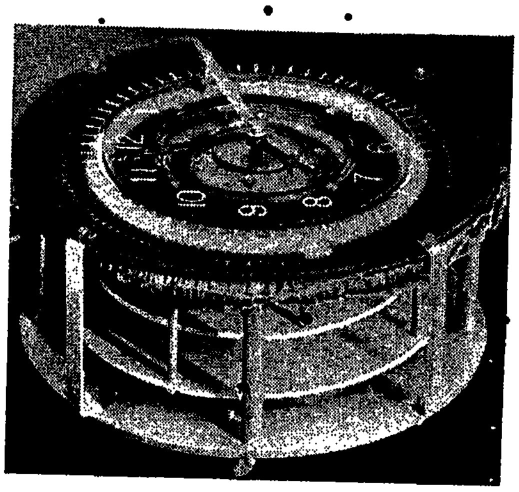
# Slow Motion Motor Will Run Indefinitely

WHILE one group of scientists has been perfecting electrical machinery that will run at higher and still higher speeds, another group has been going to the other extreme by perfecting a timing motor that will revolve only twice a day. By following the same principles the speed could be slowed down to one revolution per year or even less.





**Slow motion synchronous motor (above) as built for the experimental clock shown in the smaller view. There are only four moving parts, one for each hand and one for the split-second "spot." The clock is 10 in. in diameter and 6 in. high**

Theoretically there is no limit to the slowness that could be achieved, according to L. W. Chubb and T. R. Watts research engineers of the Westinghouse Electric and Manufacturing Company.

While the idea is still in the experimental stages and is not commercially available, the fact that it is practical and workable has been demonstrated in a clock of unique design. One feature of the clock is that it has only four moving parts, each of which is necessary to operate one of the hands. The fastest of these revolves only 60 times per minute. If the four points of wear were to be sealed in oil cups and jewels used for bearings as in good watches, the clock should run indefinitely without attention; of course such performance would require that the electric current never be interrupted.

In the accompanying illustrations are shown a view of an experimental model of the clock, together with a plan view of the slow motion motor. Just below the outer rim of the clock face is the stator of the motor having 118 iron teeth around its inside edge and wound so as to provide a revolving magnetic field. Inside this ring is the rotor around the outer edge of which are 120 iron teeth. With different numbers of teeth on the two parts, only two teeth are synchronized at any one time and there is a vernier effect around the rest of the circle. This causes the motor to move only the distance of two teeth for each revolution of the magnetic field of the stator. Thus on a 60-cycle system with the stator field revolving at the rate of 3,600 times per minute,

---

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

the rotor revolves only 60 times per minute, the speed required for a split-second hand.

Around the inner edge of the rotor ring are 122 teeth; inside this is a second rotating iron ring of still smaller diameter with 120 teeth around its outer edge. In this second reduction of speed the first rotor becomes the stator for the second, but while the first is running forward 60 revolutions, the second is running only one, so that its net progress forward is one revolution per minute. This is the speed desired for the second hand.

Attached to the second hand rotor is a permanent horseshoe magnet which creates a new rotating field in 118 iron teeth driving still another ring with 120 teeth at the rate of one revolution per hour. This runs the minute hand. Attached to the minute hand rotor is a second permanent magnet creating a rotating field in 22 teeth and driving a 24-tooth rotor one revolution every 12 hours for the hour hand. The entire operation may be explained by saying that each rotor travels only two teeth for each revolution of its magnetic field. Obviously by changing the number of teeth, any desired speed may be obtained.

# Magnet Steels and Permanent Magnets

**A new relationship connecting the open-circuit remanence of a permanent magnet with the factors which determine its value has been found. This relationship, shown by Fig. 2 of the following article, appears to be general and valid for all kinds of magnet steel. Also, criterions of magnetic quality are presented, including a nomogram chart for permanent magnet design.**

By
K. L. SCOTT

Inc., Chicago, Ill.

GENERAL STUDIES of the magnetic properties of magnet steels and permanent magnets embrace a number of related problems, prominent among them being the determination of the relation between the open circuit remanence of a permanent magnet and the various factors which determine its value. These factors include the magnetic characteristics or properties of the steel, as displayed by its hysteresis loop, and the shape and dimensions of the magnet. Of interest to the manufacturer of magnet steel are the questions of how chemical composition, and melting and rolling practise affect the magnetic and mechanical properties of the steel. The manufacturer of magnets is interested in the effect of the necessary manufacturing operations, such as heating for hot forming and annealing to increase machinability upon the flux obtainable in the finished magnet, in the tendency of the steel to warp or crack upon quenching, and in the proper hardening treatment to use.

Other special subjects may be listed, including the manner in which various influences may affect the state of magnetization of a magnet, the correlation of the microstructure and mechanical properties of a magnet steel with its magnetic properties, the determination of a suitable criterion of magnetic quality, the development of accurate and convenient testing equipment, and various other matters of greater or less importance. It is the purpose of this article to present data relating to some of the above topics which have been collected during the course of several years connection with the manufacturer of permanent magnets, both in the laboratory and in the shop.

The following symbols and notation are used in the paper. All values of $B$ are intrinsic or ferric induction.

$B_{max}$ = The value of magnetic induction corresponding to the tip of a given hysteresis loop
$H_{max}$ = the value of magnetizing force corresponding to $B_{max}$
$B_s$ = the saturation value of flux density corresponding to an infinite magnetizing force
$B_r$ = residual induction, the magnetic induction in a closed ring or infinitely long straight bar after the value of $H$ has been reduced from $H_{max}$ to 0
$H_c$ = coercive force, the value of $H$ required to reduce $B$ from $B_r$ to 0 in a ring or an infinitely long bar
$B_{rem}$ = remanence, the magnetic induction at the magnetic equator of a permanent magnet with no external magnetizing or demagnetizing force. Values of $B_{rem}$ in this paper are without pole pieces on the magnets
$L$ = the actual developed length of a magnet
$A$ = the area of cross-section of a magnet
$D$ = the equivalent diameter of a magnet = $2\sqrt{A/\pi}$
$L/D$ = the dimension ratio of a permanent magnet
$T$ = hardening temperature, absolute scale
$T_o$ = optimum hardening temperature, absolute scale
$(BH)_{max}$ = the maximum value of the product of the coordinates of the demagnetization curve for a given steel. The demagnetization curve is the portion of the hysteresis loop between $B_r$ and $H_c$

## Factors Determining Remanence of a Permanent Magnet

It was desired to determine the relationship between the remanence of a permanent magnet and the various factors which determine its value. As it was supposed that shape was one of these factors, and in order to control its influence as a variable, all tests were made upon straight bars. This form of test specimen possessed the advantages of being easily

---

Based upon "Magnet Steels and Permanent Magnets—Relationships Among Their Magnetic Properties" (No. 32-24) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25–29, 1932.

obtainable, easily duplicated, and well adapted to the measurement of magnetic properties in a permeameter as well as to remanence measurements with a search coil.

Accordingly, a large number of straight bars was collected during the course of several laboratory investigations. Each of the bars was 12 in. in length. In the lot were bars of $^1/_8 \times 1^1/_2$ in., $^1/_4 \times ^1/_4$ in., $^3/_{16} \times ^3/_4$ in., $^1/_4 \times 1^1/_4$ in., $^3/_4 \times ^5/_8$ in. and $^3/_8 \times ^1/_2$ in. cross-sections. All available types of steel were represented, including a 0.9 per cent chrome steel, a 3.5 per cent chrome steel, a 0.85 per cent manganese steel, a 5 per cent tungsten steel, and 20 per cent, 25 per cent, and 36 per cent cobalt steels. The range in coercive force was from 40 to 260 oersteds accompanied by values of residual induction varying from 6,000 to 11,000 gausses.

## EXPERIMENTAL PROCEDURE

The test bars were hardened in the manner appropriate to each kind of steel, except that some bars purposely were quenched from a high temperature in order to secure low values of $B_r$. After hardening, the demagnetization curve for each bar was determined by means of permeameter measurements, using the Babbitt permeameter and a Grassot flux meter with lamp and scale. The control circuit of this permeameter is the conventional circuit for a ring test. All magnetic data are comparable since all of the test specimens were measured by the same instrument. (See "An Improved Permeameter for Testing Magnet Steel," by B. J. Babbitt, *Opt. Soc. Amer. Jl.*, v. 17, 1928, p. 47.)

Following the permeameter measurements each bar was magnetized as a straight bar magnet in an air core solenoid. Field strengths of over 1,000 oersteds were applied to each bar. Upon removal from the solenoid the flux density at the middle of the bar was measured by means of a search coil and the Grassot flux meter with lamp and scale. This is the quantity referred to as $B_{rem}$ in this article.

After the measurements at 12-in. lengths were completed, each bar was cut by removing 1 in. of material at each end, to successive lengths of 10, 8, 6, 4, and 2 in., except that in the case of some of the bars of larger cross-section the lengths of 10, 6, and 2 in. were omitted. Remanence measurements were made at each of the above lengths. The bars were remagnetized for each new measurement of $B_{rem}$.

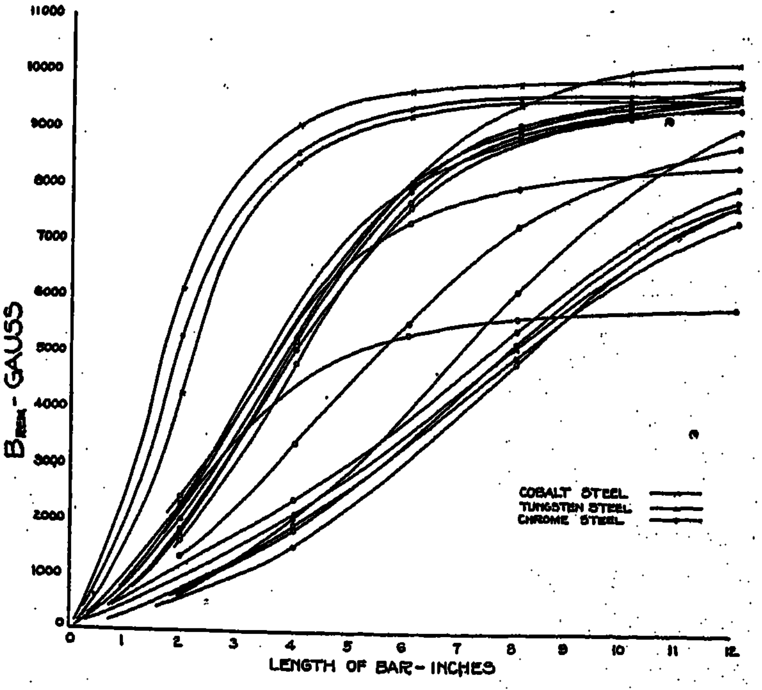

**Fig. 1. Remanence versus length for straight bar magnets of different cross-sections and materials**

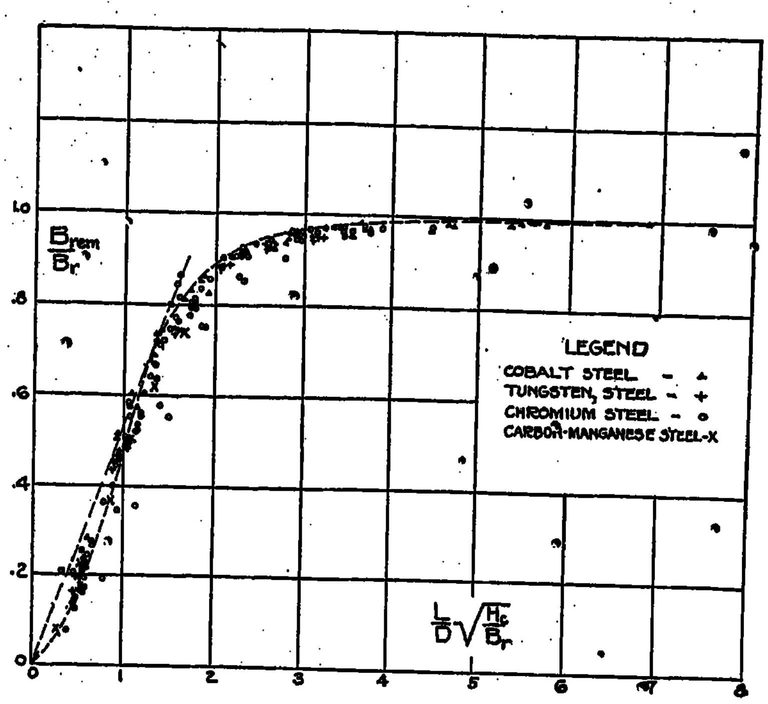

**Fig. 2. Correlation between the combinations of variables indicated, for bars of any kind of material, magnetic properties, length, and cross-section. Same data as in Fig. 1**

The foregoing experiments made available for analysis a wide range of values of the associated variables $B_{rem}$, $B_r$, $H_c$, $L$, and $A$.

## ANALYSIS OF DATA

For a number of the specimens the values of remanence versus length are plotted in Fig. 1 to show the range of values existing in different bar magnets of the same length, but of different cross-sections and materials when fully magnetized. The differences in $B_{rem}$ for a particular length of bar are due to the differences in $B_r$, $H_c$, and cross-section of the various specimens. The chief characteristics that the several curves of Fig. 1 have in common are a general resemblance in shape to a normal induction curve, and an asymptotic approach to limiting values of $B_{rem}$ as the lengths increase.

In Fig. 2 is shown the result of plotting $\frac{B_{rem}}{B_r}$ against $\frac{L}{D}\sqrt{\frac{H_c}{B_r}}$ for the same set of bars. The combination of variables $\frac{L}{D}\sqrt{H_c}$ was arrived at by a purely cut-and-try process, but it was later suggested to the writer that it would be preferable to use $\frac{L}{D}\sqrt{\frac{H_c}{B_r}}$. In either case, a surprisingly good correlation is obtained.

As shown in Fig. 2, a line drawn through the origin and tangent to the dotted curve of that figure has its point of tangency at values of $\frac{B_{rem}}{B_r}$ and $\frac{L}{D}\sqrt{\frac{H_c}{B_r}}$ of approximately 0.65 and 1.25, respectively. It will be shown later that this is the point of maximum efficiency; *i. e.*, the point at which are obtained the highest values of $B_{rem}$ or external magnetic energy per unit volume of steel. It follows that magnets should be so designed that $\frac{L}{D}\sqrt{\frac{H_c}{B_r}} = 1.25$ and $\frac{B_{rem}}{Br} = 0.65$. The nomogram of Fig. 3 was laid out on this basis. The use of this chart to design a magnet of maximum efficiency is illustrated by the dotted lines of the figure. In the case shown, a total flux in the magnet of 3,000 maxwells is desired, and a steel with a $B_r$ of 10,000 gausses and a coercive force of 54 oersteds is assumed. The correct values of $A$ and $L$ are found to be 0.461 sq. cm. and 13 cm., respectively, and the dimension ratio is 17. If the nomogram is applied to the design of other than straight bar magnets, the length given by the chart will be too great, depending upon how close the poles of the magnet come to each other.

## CRITERIONS OF MAGNETIC QUALITY OF PERMANENT MAGNET STEELS

A number of quantities determinable by magnetic measurement has been proposed at various times by different investigators for use as criterions of the magnetic quality of magnet steels. Among these may be listed $(BH)_{max}$, $B_rH_c$, $B_r/B_{max}$, $(B_rH_c)/(B_{max})$ and $B_r/H_c$. The first of these criterions is discussed in "Permanent Magnets in Theory and Practise," S. Evershed. *Instn. Elec. Eng. Jl.*, v. 58, 1920, p. 780, and v. 63, p. 725, 1925; the second in "Ein neues Material für Permanente Magnete," E. Gumlich, *Elektrotech. Zeitsch.*, v. 44, 1923, p. 147; and the last criterion is discussed in the following two articles by J. A. Mathews: "Magnetic Habits of Alloy Steels," *Am. Soc. Testing Matl. Proc.*, V. 14, 1914, p. 50; and "Retained Austenite—a Contribution to the Metallurgy of Magnetism," *Am. Soc. for Steel Treating Trans.*, Nov. 1925, p. 565.

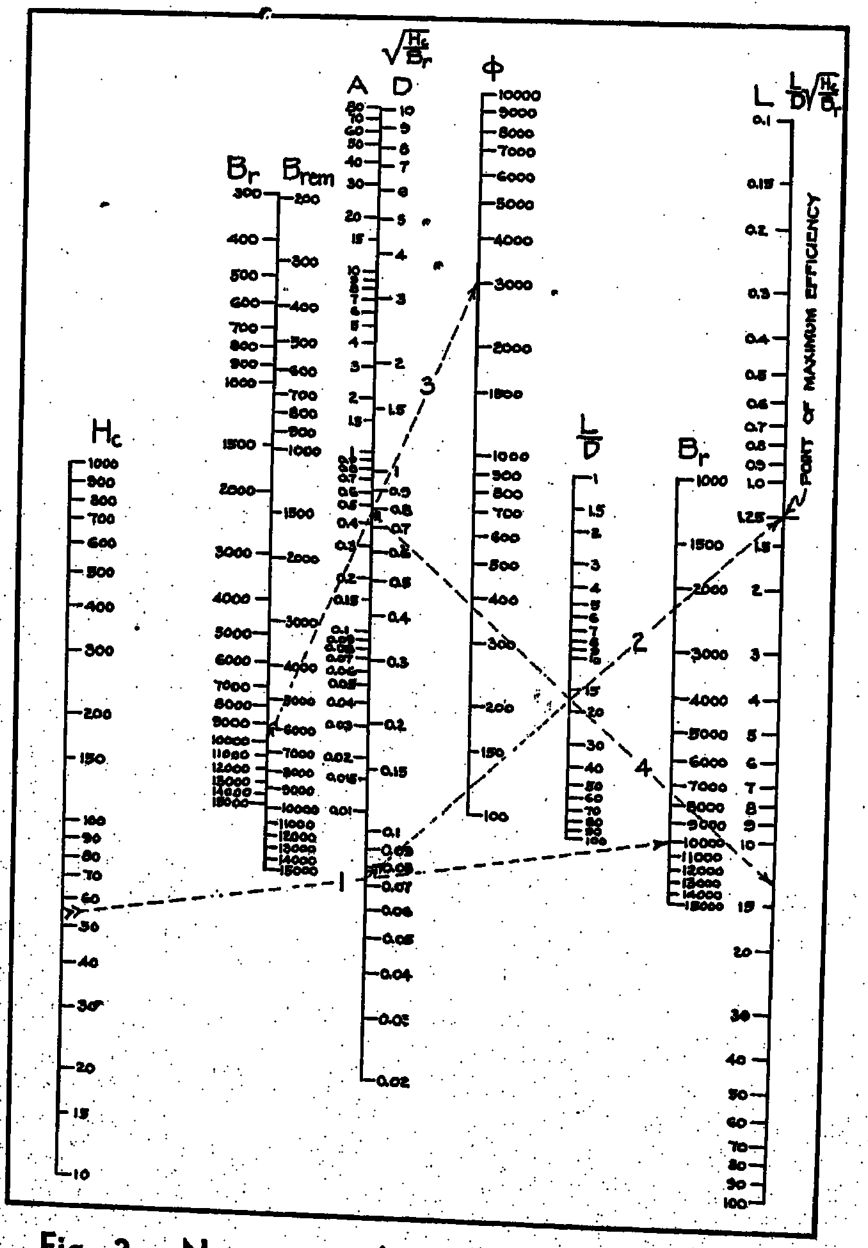

**Fig. 3. Nomogram chart for permanent magnet design for maximum efficiency. Based on the curves of Figs. 1 and 2**

The quantity $(BH)_{max}$ was proposed by S. Evershed, and his theoretical justification for it is convincing, but an experimental verification seemed desirable. Data from the bars shown in Fig. 3, and others, were used for this purpose. These data are shown on Fig. 4. For each bar there is plotted, from left to right, its demagnetization curve as determined in the permeameter, the derived curve of $BH$ versus $B$, and the curve of $B_{rem}$ in terms of length, all plotted to the same scale of $B$. Fig. 4 shows that if tangents to the curves of $B_{rem}$ versus length are drawn through the origin, the point of tangency in each case indicates the value of $B_{rem}$ and length for which the value of $B_{rem}/length$, or $B_{rem}/volume$, is a maximum. It is clearly shown that in each case these values of $B_{rem}$ coincide with the values of $B$ for which the product $(BH)$ is a maximum, thus indicating that the $(BH)_{max}$ point is the point of maximum efficiency for the magnet, while a comparison of the curves shows that the value of $(BH)_{max}$ is a measure of the efficiency or quality of the steel. It is believed therefore that the quantity

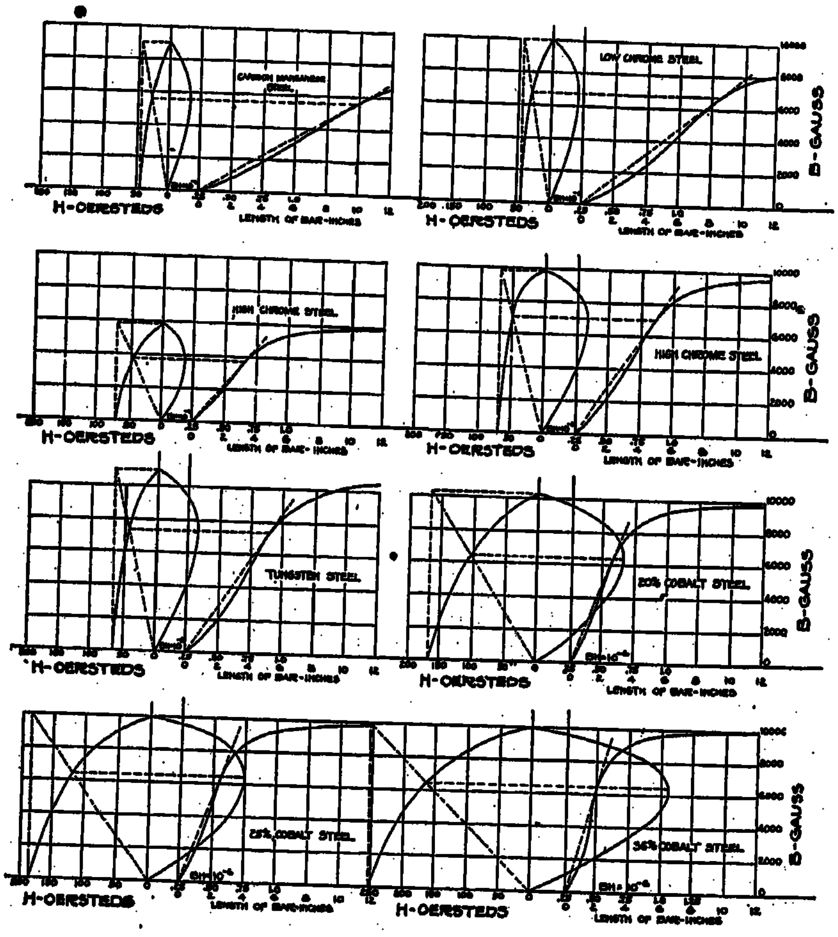

**Fig. 4. Experimental verification of validity of Evershed's criterion for magnetic quality of permanent magnet steels**

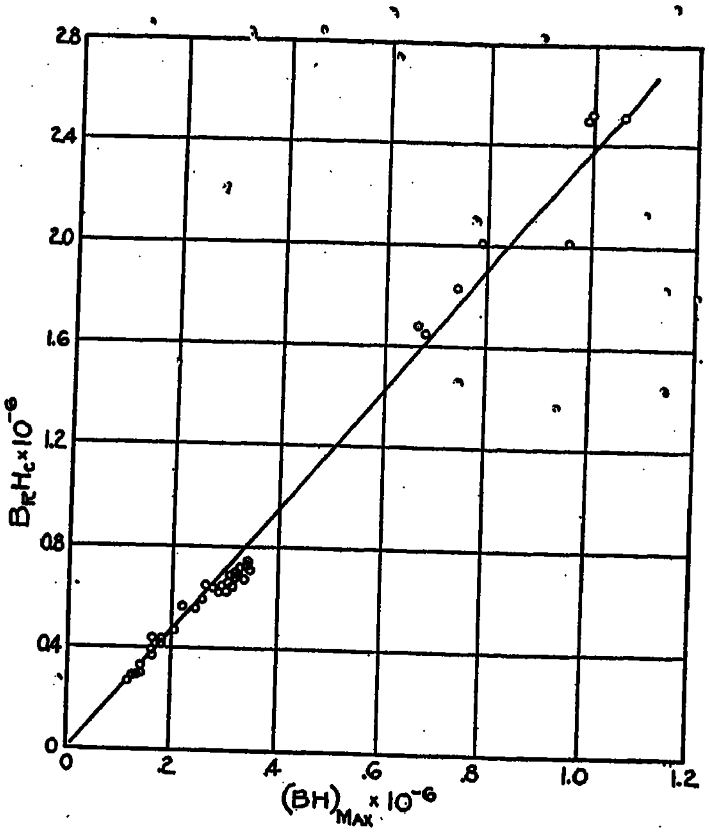

**Fig. 5.** Relation between the quantity $B_rH_c$ and Evershed's criterion $(BH)_{max}$

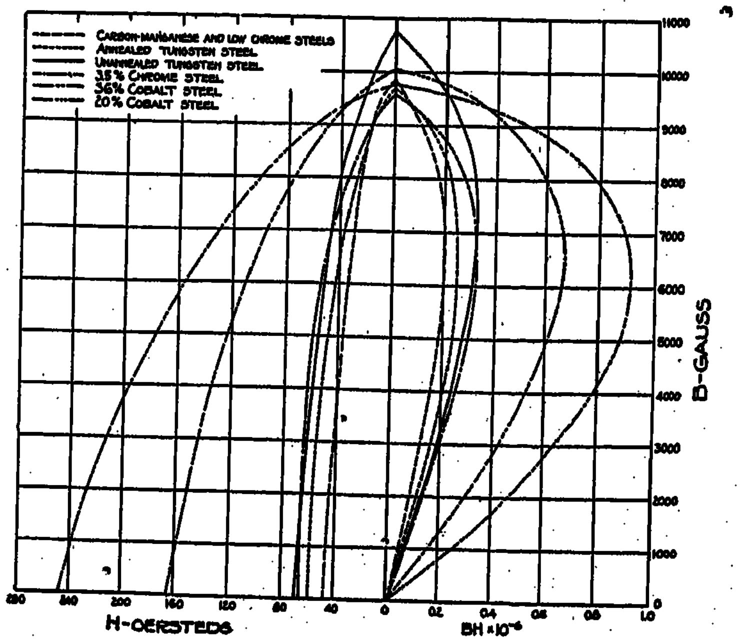

**Fig. 6.** Typical demagnetization curves and curves of *BH* versus *B* for various kinds of magnet steel

$(BH)_{max}$ furnishes a wholly reliable measure of the quality of a permanent magnet steel. It can be used to select from a choice of compositions or heat treatments the one which is the best in terms of magnetic energy in the air-gap of the magnet per unit volume of steel in the magnet. The optimum hardening temperature, previously referred to, is defined as the hardening temperature at which is obtained the maximum value of $(BH)_{max}$ for a given type of steel.

The product $B_rH_c$ is shown by Fig. 5 to bear an approximately linear relationship to $(BH)_{max}$, and as $B_rH_c$ can be determined with less effort, it is preferable for routine use as a criterion. The other quantities mentioned are all open to serious objection as being in some cases either meaningless or actually misleading. A number of typical demagnetization curves and the derived curves of $BH$ plotted against $B$ is given in Fig. 6.

# Supervisory Control for A-C. Electrified Railroads

IN ITS ELECTRIFICATION in and around Philadelphia, the Pennsylvania Railroad has made use of two installations of supervisory control for the remote operation of high voltage a-c. step-down substations. In a current A.I.E.E. paper (see footnote) C. P. West (M'28) Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., and H. C. Griffith, Pennsylvania Railroad Company, Philadelphia, Pa., describe some of the features of the installation and relate in detail how some of the difficulties encountered were solved.

When the electrification was put into service, interference with the supervisory equipment was experienced from induced voltage in the control wires when the trolley circuits were fed from one end. This interference was evidenced by chattering of the relays, and flashing over, and sometimes destruction, of the protector tubes; in case of trolley fault, fuses were blown.

After attempting by several other means, to obviate the disturbing effects of the induced voltages, one of the installations was rebuilt using a new method of control known as the *visicode* system, brought out by the Westinghouse company. This scheme utilizes only two line wires and operates by means of d-c. unidirectional impulses; it is ideally suited to the limiting of effects of low frequency induction. A special reactor connected in each end of the control system line is said to be the key to the successful application of this circuit. With this arrangement a low induced current can flow continuously in the two supervisory, line wires without flashing the protector tubes or interfering with operation. A high quality of operation has been obtained since the rebuilding of this installation. In the second installation, the synchronous visual set originally installed has a rather short line circuit and is not so closely located to contact line circuits; this original equipment continues to give good operation.

When these types of supervisory control equipment have been adjusted properly, they are said to operate with very little maintenance; where the equipment is in a clean neighborhood and is operating satisfactorily, inspection periods can be extended to as long as four months. In conclusion the authors state that, "The results obtained by the Pennsylvania Railroad have shown that when the substations are located where control points are so distant that the installation of direct control cables is not economical, control can be adequately obtained by the use of proper supervisory equipment.... It may be safely stated that supervisory control is destined to play an increasingly important part in future railroad electrification."

---

Abstracted from "Supervisory Control for A-C. Electrified Railroads" (No. 31-93) by C. P. West and H. C. Griffith, presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1931.

# Standard Decrement Curves

**Standard decrement curves in use for a number of years in the calculation of power system voltages and currents under fault conditions now have been revised and are presented herewith. Their use enables the determination of the magnitudes of voltages and currents for various intervals of time subsequent to the occurrence of a fault.**

By

**C. F. WAGNER**
MEMBER A.I.E.E.
Westinghouse Elec. & Mfg.
Co., East Pittsburgh, Pa.

APPLICATION of circuit breakers and relays on power systems frequently requires a determination of the magnitude of voltages and currents under fault conditions for various intervals of time measured from the instant of the application of the fault. The decay of fault current from initial to sustained values commonly is determined by means of decrement curves. A standard set of decrement curves was published for the first time in 1918 (see reference 1 in bibliography). These were revised in 1923, and published in the N.E.L.A. Relay Handbook (1926) and in various manufacturers' publications.

In the past eight years there has been considerable progress in the analysis of transients in synchronous machines. Furthermore, the method of symmetrical components has come into general use for the calculation of unbalanced faults. These developments in theory, together with the increased knowledge of machine constants, have made desirable a new set of decrement curves. Such a set now has been prepared and is given in Figs. 1 and 2. These curves have been approved by the National Electrical Manufacturers Association.

## REFINEMENTS SECURED

A single decrement for the a-c. component of fault current was assumed for the 1923 decrement curves. The new curves take into consideration the fact that the a-c. component is made up of two exponential terms and the fact that the transient time constant varies with system reactance. The method of using the curves includes a means to give more accurate results in case the time constants of machines differ appreciably from the assumed average figures upon which the curves are based.

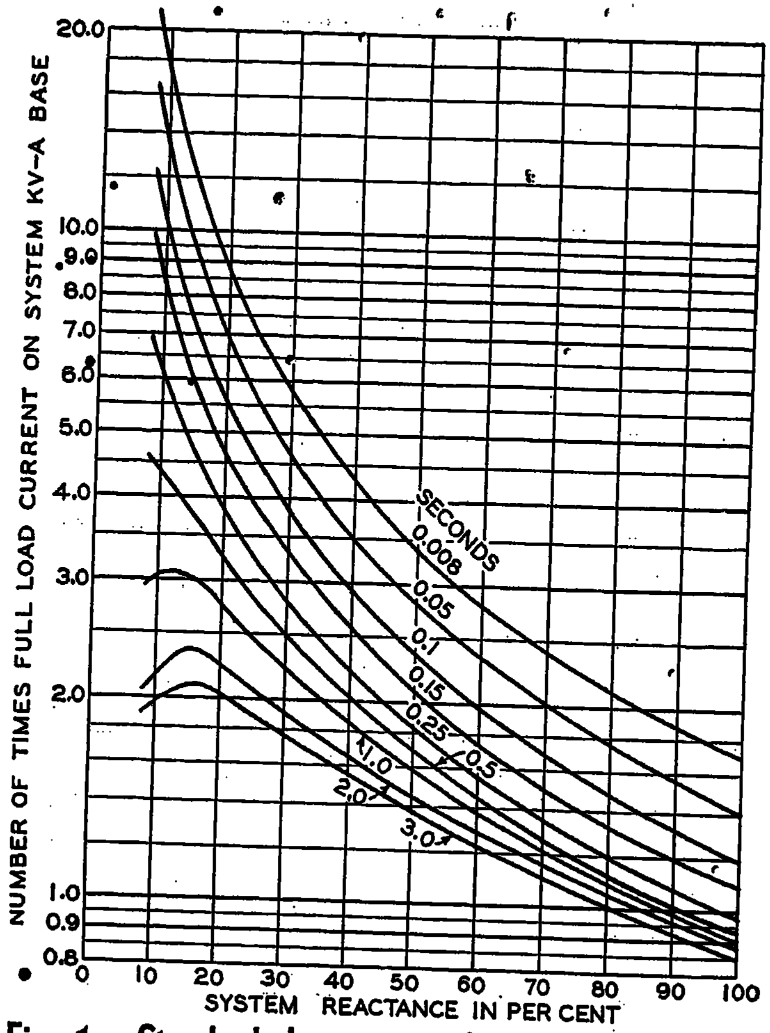

Fig. 1. **Standard short-circuit decrement curves for synchronous machines**

System reactance must be based on system kva. and not on the particular kva. chosen as a base for calculations. System kva. is connected synchronous capacity in kva.

These curves are based on $T'_{do} = 5$ sec. For other values multiply actual times by $\frac{5}{T'_{do}}$ to get equivalent times to use in curves.

For three-phase short circuit—
  Reactance—Use system reactance to the point of fault
  Times full load (normal) scale—use scale reading
For line-to-line short circuit—
  Reactance—Use two times system reactance for three-phase fault
  Times full-load (normal) scale—Multiply scale reading by $\sqrt{3}$
For line-to-ground short circuit—
  Reactance—Use $(2x_1 + x_0)$ or

$$\frac{3 \times (\text{initial three-phase short-circuit current})}{(\text{initial line-to-ground short-circuit current})} \times \text{system reactance for three-phase fault}$$

  Times full-load (normal) scale—Multiply scale reading by 3

Three separate groups of curves, one for each type of fault, namely, three phase, line-to-line, and line-to-ground, were included in the 1923 curves. The new decrement curves include only a single set which, however, is applicable to the same three types of faults. This is feasible because the new curves are based upon the method of symmetrical components. The old curves assume equal initial values of line-to-line and three phase currents whereas the present curves are plotted for the more usual ratio of 0.866. The old curves for line-to-ground faults were re-

---

Based upon "Standard Decrement Curves" (No. 32-53) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25–29, 1932.

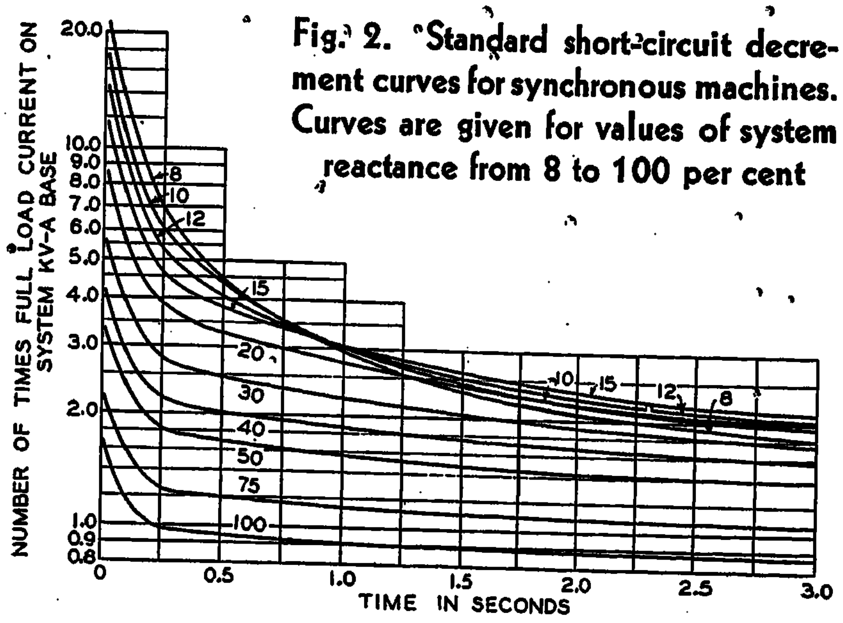

Fig. 2. Standard short-circuit decrement curves for synchronous machines. Curves are given for values of system reactance from 8 to 100 per cent

stricted to the particular case of a fault on the terminals of one or more generators all the neutrals of which were solidly grounded; the new curves were not restricted in this respect.

No distinction was made between machines with and without damper windings in the 1923 curves, while the present set has been designed to apply particularly to salient pole machines with amortisseurs, and to turbine-alternators. They therefore give inaccurate results for the first 0.2 sec. for salient pole machines without damper windings and are supplemented by a method of calculation which gives the initial value of short-circuit current accurately for these machines.

## BASIC ASSUMPTIONS

The basic assumptions from which the new curves have been derived are as follows:

1. Immediately preceding the short circuit the generators are operating at rated voltage and kilovoltamperes at 80 per cent power factor.

2. No automatic voltage regulator is used.

3. The actual system subjected to fault may be represented by a single equivalent generator of the same total rating and an external reactance.

4. The load is located at the machine terminals; the machine reactance is taken as 15 per cent unless the total reactance is less than 15 per cent, in which event all the reactance is assumed to be in the machine.

5. The short circuit occurs on an unloaded feeder.

6. The short circuit occurs at the point of the voltage wave which corresponds to maximum possible instantaneous current.

7. All resistance in the circuit including the resistance of the fault is neglected.

8. All the machine e.m.f.'s are in phase.

9. The machine reactances and time constants are those of representative modern machines. Of particular importance is the relation between transient and subtransient reactance of machines as shown in Fig. 3.

## APPLICATION OF STANDARD DECREMENT CURVES

The decrement curves of Figs. 1 and 2 give the r.m.s. total current expressed in terms of "times normal current" with total connected synchronous capacity in kilovoltamperes as a base. The same data are given in both figures, system reactance in per cent being used for the abscissas of Fig. 1, while elapsed time in seconds is used as the abscissas of Fig. 2. The curves of either figure may be used, depending upon convenience. The instructions for use given below Fig. 1 apply also to Fig. 2.

The reactance to be used with the curves for any kind of a fault may be obtained by means of analytical calculation, by the use of the calculating board, or, if the initial values of symmetrical short-circuit currents happen to be known from other sources, indirectly by substitution in the formulas below Fig. 1. In order to choose the proper decrement curve it is essential that the reactance used to select a curve in Fig. 2, or a line in Fig. 1, be expressed as a per cent of the total connected synchronous capacity in kilovoltamperes rather than as is common practise, an arbitrary value conveniently chosen to expedite system calculations.

If the system open circuit time constant $T'_{do}$ referred to the point of fault is known to be other than 5.0 sec., the time scale of the curves may be corrected to conform to it by means of the formula given below Fig. 1. Other information on this subject may be found in references 4 and 5.

## THREE PHASE SHORT CIRCUIT

The reactance to be used to select the proper decrement curve for a three phase fault, is what is commonly spoken of as the "system reactance" referred to or viewed from the point of fault. It is the reactance used with the decrement curves formerly published. When determining this reactance it is important that synchronous machines be represented by their subtransient reactances, and that all loads other than synchronous be neglected. Proper account has been taken of these loads for the average system in deriving the decrement curves.

The subtransient reactance just mentioned is the reactance to use in determining the r.m.s. initial

Table I—Typical Range and Average Values of Constants for Three Phase 60-Cycle Synchronous Machines

| | $x_d$ | $x_d''$ | $x_2$ | $x_0$* |
|---|---|---|---|---|
| Turbine-generators | 0.95 to 1.45 (avg. 1.10) | 0.07 to 0.17 (avg. 0.12) | $= x_d''$ | 0.01 to 0.14 (avg. 0.03) |
| Salient pole motors and generators (with amortisseurs) | 0.60 to 1.45 (avg. 1.10) | 0.13 to 0.35 (avg. 0.22) | $= x_d''$ (nearly) | 0.02 to 0.20 (avg. 0.06) |
| Waterwheel generators (no amortisseurs) | 0.60 to 1.45 (avg. 1.10) | $0.85x_d'$ | 0.30 to 0.70 (avg. 0.50) | 0.04 to 0.22 (avg. 0.07) |
| Condensers | 1.50 to 2.20 (avg. 1.80) | 0.18 to 0.38 (avg. 0.25) | 0.17 to 0.37 (avg. 0.24) | 0.02 to 0.15 (avg. 0.08) |

NOMENCLATURE

$x_d$ = direct axis synchronous reactance (unsaturated)
$x_d'$ = direct axis transient reactance (saturated)
$x_d''$ = direct axis subtransient reactance (saturated)
$x_1$ = positive sequence reactance
$x_2$ = negative sequence reactance
$x_0$ = zero sequence reactance (saturated)

SUPPLEMENTARY DATA

For test data of specific machines, refer to bibliography item 14.
$x_d'$ = for waterwheel generators (saturated) = 0.20 to 0.45 (avg. 0.35)
$x_d''$ = for turbine-generators and salient pole machines with amortisseurs (saturated) from Fig. 3

*$x_0$ varies so critically with armature winding pitch that the average values given are not very dependable.

value of the a-c. component of short-circuit current. It includes the effect of induced currents in damper windings, etc., which have a very rapid decrement. The transient reactance on the other hand determines the a-c. component when the rapidly decaying component is neglected, while the synchronous reactance is used to determine sustained values of current.

Means for obtaining the system reactance referred to the point of fault, and the corresponding short-circuit current has been developed fully in other papers[6–11] and is not discussed here. In case synchronous machine reactances or time constants are not known, Table I and Figs. 4 and 5 may be used as a guide in selecting reasonable values.

The system reactance referred to the point of fault assists in the selection of the proper decrement curves which gives the three phase r.m.s. short-circuit current or kva. in "times normal" at any time after the occurrence of the short circuit, subject to the assumptions previously given.

## Line-to-Line Short Circuit

For a line-to-line short circuit the fault current is determined by the use of the standard decrement curves of Figs. 1 and 2 in the same manner as the three-phase short-circuit current by using a reactance equal to twice the system reactance (the value used for three-phase short-circuit calculation) and multiplying the resulting current in times normal read from the curves by $\sqrt{3}$. This rule results from the theory of symmetrical components,[7,8,9,11] assuming the negative phase sequence reactance of the system as measured from the point of fault to be equal to the system reactance $x_1$. Where the negative phase sequence of the system is known, more accurate results may be obtained by using a reactance equal to the sum of the system reactance $x_1$ and the negative phase sequence system reactance $x_2$ instead of twice the system reactance $x_1$. The negative phase sequence reactance of the system is obtained in the same manner as the system reactance $x_1$ except that the negative phase sequence reactance of the machines is substituted for the subtransient reactance of machines.

## Line-to-Ground Fault

For line-to-ground faults, the decrement curves of Figs. 1 and 2 still may be used, provided the ratio of the instantaneous values of three-phase fault current to line-to-ground fault current, or the proper value of reactance, is known. For this case the reactance may be taken as three times the system reactance ($3\ x_1$) multiplied by the ratio of the three phase current to the line-to-ground short-circuit current. Ordinarily the line-to-ground short-circuit current must be calculated by the method of symmetrical components or the reactances for the different sequences used as outlined in the paragraph following. At any time the line-to-ground current will be equal to three times the value of "times normal current" read from the decrement curves using the above values for system reactances.

**Table II—Initial R.M.S. Alternating (Symmetrical) Current**

| | | | | | |
|---|---|---|---|---|---|
| Reactance on decrement curve | 8 | 10 | 12 | 15 | 20 |
| Initial symmetrical current | 12.3 | 9.96 | 8.38 | 6.88 | 5.11 |
| Reactance on decrement curve | 30 | 40 | 50 | 75 | 100 |
| Initial symmetrical current | 3.37 | 2.52 | 2.01 | 1.33 | 1.00 |

The value of reactance to be used with the curves for a line-to-ground short circuit may be determined, using the method of symmetrical components, the reactance being taken as the sum of the positive, negative, and zero sequence reactances of the system ($x_1 + x_2 + x_0$) as measured from the point of fault. For ordinary calculations it is sufficiently close to use a reactance equal to $2\ x_1 + x_0$, where $x$ is the system reactance used for three-phase short-circuit calculations and $x_0$ is the zero phase sequence reactance of the system. The zero phase sequence reactance may be obtained in a manner similar to that used for the determination of the system reactance for three phase short circuits by changing the reactances in accordance with the following rules:

| | |
|---|---|
| Ungrounded transformers | = ∞ |
| *Grounded $\Delta$-$Y$ transformers | = ordinary reactance to neutral on $Y$ side and open-circuited on $\Delta$ side |
| Neutral impedance | = 3 × actual impedance in neutral |
| Single circuit aerial lines (no ground wires) | = 3.5 × ordinary reactance |
| Double circuit aerial lines (no ground wires) | = 5.5 × ordinary reactance of double line |
| Single-circuit aerial lines (copper or aluminum ground wires) | = 2.0 × ordinary reactance |
| Double circuit aerial lines (copper or aluminum ground wires) | = 3.0 × ordinary reactance of single line |
| Cables, three phase | = 3 to 5 × ordinary reactance |
| Cables, single phase | = 1.0 × ordinary reactance |

*Replace by circuit which permits current to flow from $Y$ side to ground but not on $\Delta$ side.

For auto-transformers, grounding transformers, and other special apparatus, refer to papers and articles which discuss the determination of the zero phase sequence impedance in more detail.[8,12,13]

## Minimum Fault Current

For certain relay applications it is sometimes necessary to know the total r.m.s. alternating fault current, *i. e.*, with no d-c. component, rather than the maxi-

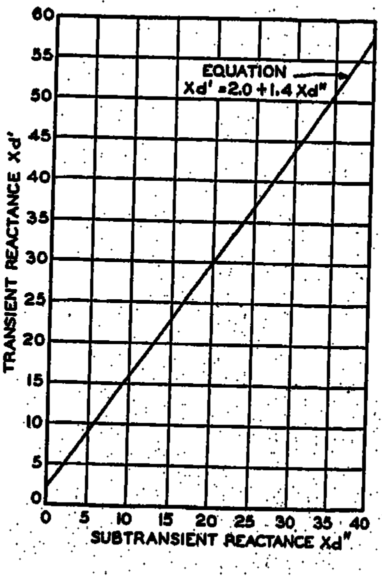

**Fig. 3. Relation between $x_d'$ and $x_d''$ (saturated values) for three phase synchronous machines**

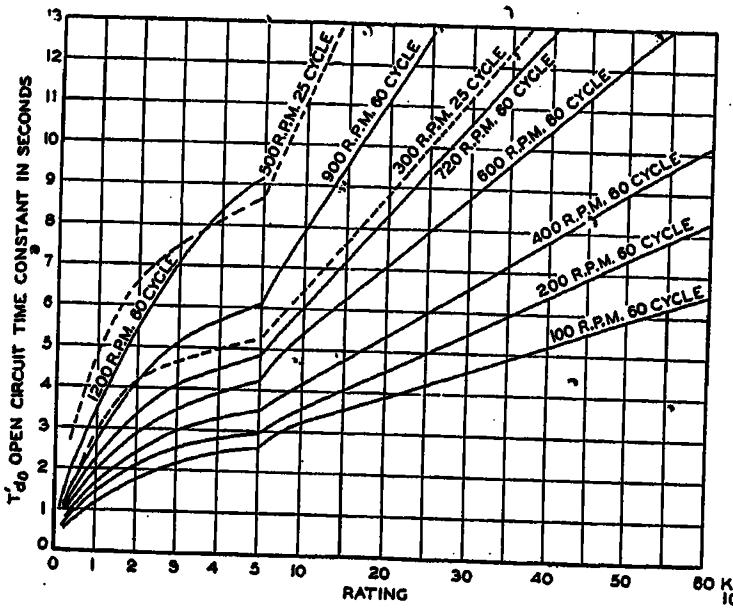

**Fig. 4. (Left)** Open-circuit time constants of a-c. generators and motors

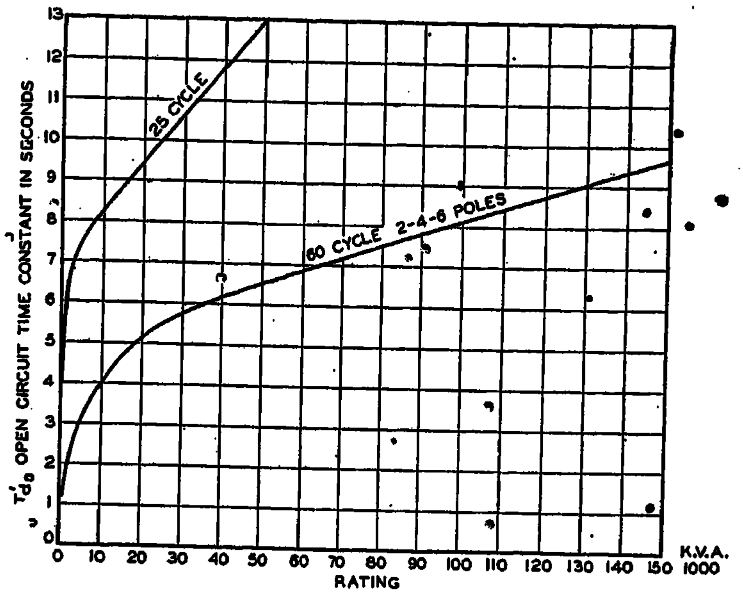

**Fig. 5. (Right)** Open-circuit time constants of turbine generators

mum current at any time as given by the standard decrement curves which are based upon an asymmetrical fault. The initial r.m.s. alternating (symmetrical) currents for values of system reactance are given in Table II.

As the asymmetrical component is negligible after 0.3 sec., the r.m.s. alternating (symmetrical) current for any time less than 0.3 sec. may be obtained by interpolation between the initial value obtained from the above table and the curve values at 0.3 sec. Satisfactory results can be obtained readily by sketching in a curve starting from the initial r.m.s. alternating (symmetrical) current and making it tangent to the corresponding standard decrement curve at 0.3 sec.

### SALIENT POLE MACHINES WITHOUT DAMPERS

Where salient pole machines without damper windings supply the short-circuit current the standard decrement curves give good results after 0.2 sec., provided that for these machines the equivalent subtransient reactances are obtained from the known transient reactances by means of the relation given in Fig. 3; however, the initial values indicated by standard decrement curves may be 30 per cent too high. If more accurate values of initial current are desired, it is necessary to make a separate calculation of the system reactance using the actual value of the subtransient reactance of the salient pole machines without damper windings instead of the equivalent value obtained from the transient reactance by means of the relation given in Fig. 3. A curve readily may be sketched between the new initial point and the 0.2 sec. point on the standard decrement curve corresponding to the equivalent subtransient reactance of Fig. 3.

The subtransient reactance of machines without damper windings generally has been taken as equal to the transient reactance. However, there is an appreciable subtransient component in the short-circuit current of such a machine due to the damping action of the pole rivets and other closed circuits, and also due to the rapidly disappearing effects of saturation. The test data available indicate that the subtransient reactance of a machine without damper windings should be taken as about 85 per cent of the transient reactance.

### LIMITATIONS OF THE STANDARD CURVES

There are certain limitations in the application of standard decrement curves that should be recognized. The decrement curves with the supplementary methods will give safe values for circuit breaker application, except possibly in unusual cases. However, for relay application, it is frequently insufficient to know that the current does not exceed a particular maximum value but instead it is important to know the minimum current values under given fault conditions. In deriving the curves, it was assumed that the system could be replaced by a single equivalent generator. If the initial currents supplied to the fault by the several machines are not in proportion to their ratings, then the division of the sustained currents will not be proportional to the initial current division. Furthermore, the total current will actually be considerably smaller. For example, if a large part of the initial short-circuit current is supplied by a machine the rating of which is a small fraction of the total kva., the curve may give a sustained value that is more than 100 per cent too high. It has been assumed also that the system is fully loaded, so that if the decrement curves are used in the case of a system which is only partially loaded, it is evident that the sustained current will be less than the values given by the curves. Further it has been assumed that all of the generated e.m.f.'s are in phase. Departures under operating conditions from this assumption result in smaller values of current.

When voltage regulators are used there will be a tendency to increase the current over that given by the decrement curves. For the first 0.2 sec. the fault current will ordinarily be unaffected but the sustained current may be increased in proportion to the ratio of the maximum exciter voltage to the nominal exciter voltage corresponding to rated voltage and kva. at 80 per cent power factor. For ordinary excitation systems, *i. e.*, where quick response systems are not used, the sustained currents may be increased as much as 50 per cent by the action of the voltage regulators.

In general, for systems with characteristics radically different from the assumptions upon which the standard curves are based it may be necessary to use more accurate methods of calculation. (*Editor's note*—Steps toward the refinement of such methods have been taken and are presented in references 2 and 3.)

## EXAMPLES

The following two numerical examples illustrate the manner in which the standard decrement curves are used. For the first illustration let it be assumed that the system voltage is 66 kv. and the following data have been obtained either analytically or by use of a calculating board:

Total connected synchronous capacity = 5,500 kva.
Initial r.m.s. alternating component, three-phase short-circuit current...... = 480 amperes (55,000 kva.)
Initial r.m.s. alternating component of line-to-ground short-circuit current... = 570 amperes (65,000 kva.)
(The short-circuit kva. for a line-to-ground fault is equal to $\sqrt{3}$ times the product of fault current and system voltage.)

The system reactance is then

$$\frac{5{,}500}{55{,}000} \times 100 = 10 \text{ per cent}$$

The three-phase short-circuit current at 0.3 sec. is desired. Referring to Fig. 2 and following along the 10 per cent reactance curve to 0.3 sec. time it is found that at this time the short-circuit current or kva. is 5.6 times normal. Thus the short circuit kva. at 0.3 sec. is

$$5.6 \times 5{,}500 = 30{,}800 \text{ kva.}$$

Since the short circuit occurred on a 66-kv. line, the corresponding short-circuit current is

$$\frac{30{,}800}{66 \times \sqrt{3}} = 269 \text{ amperes}$$

If the equivalent open-circuit time constant of the system is 3.0 sec. instead of 5.0 sec. then the time to be used with the curves corresponding to 0.3 sec. is in accordance with the formula given below, Fig. 1.

$$0.3 \times \frac{5.0}{3.0} = 0.5 \text{ sec.}$$

For this value of time a value of 4.3 times normal is read from the curve, and the three-phase short-circuit kva. at 0.3 sec. becomes

$$4.3 \times 5{,}500 = 23{,}600 \text{ kva.}$$

For a line-to-line short circuit the reactance to be used with the curves is twice the system reactance used to find the three-phase short-circuit kva. It is

$$10 \text{ per cent} \times 2 = 20 \text{ per cent}$$

This reactance at 0.5 sec. on the curve of Fig. 2 gives 3.3 times normal, which when multiplied by $\sqrt{3}$ is 5.72 times normal. The magnitude of the line-to-line short circuit at 0.3 sec. is then

$$5.72 \times 5{,}500 = 31{,}500 \text{ kva.}$$

The line-to-ground short-circuit reactance is found from the formula on the curve sheet as

$$\frac{3 \times 65{,}000}{55{,}000} \times 10 = 35.5 \text{ per cent}$$

The line-to-ground short-circuit kva. is found by interpolation for 0.5 sec. to be 2.2 times normal which multiplied by 3 gives 6.6 times normal as the line-to-ground short-circuit kva. at 0.3 sec., *i. e.*,

$$6.6 \times 5{,}500 = 36{,}300 \text{ kva.}$$

Since this fault occurred on a 66-kv. line the line-to-line ground short-circuit current at 0.3 sec. is

$$\frac{36{,}300}{66 \times \sqrt{3}} = 317 \text{ amperes}$$

As a second illustration, a system having only water-wheel generators without amortisseur windings will be considered. The system has a total synchronous capacity of 8,000 kva., a transient reactance of 38 per cent, of which 15 per cent is external, and an open-circuit time constant of 5 sec. The three-phase short-circuit currents at 0.1 and 2.0 sec. are desired.

The curves of Fig. 2 give the decrement after 0.2 sec. quite accurately if the proper transient reactance is used to select the curve. Referring to Fig. 3 the subtransient reactance corresponding to a machine transient reactance of 23 per cent is 15 per cent. The system equivalent subtransient reactance is

$$15 \text{ per cent} + 15 \text{ per cent} = 30 \text{ per cent}$$

Using the 30 per cent curve of Fig. 2, the times normal value at 2.0 sec. is found to be 1.9. Thus the three phase short circuit is

$$1.9 \times 8{,}000 = 15{,}200 \text{ kva.}$$

The more accurate method is necessary in determining the short-circuit current at 0.1 sec. By referring to Table I it is found that the subtransient reactance of a waterwheel generator without an amortisseur is about 85 per cent of its transient reactance. So this equivalent waterwheel generator machine has a subtransient reactance of

$$23 \times 0.85 = 19.6 \text{ per cent}$$

Adding to this the external reactance, the system subtransient reactance which determines the initial short-circuit current is obtained:

$$19.6 + 15 = 34.6 \text{ per cent}$$

By interpolation between the curves of Fig. 2, the initial three phase short circuit is found to be 4.8 times normal. From the curve sketched in connecting this value to the 30 per cent curve at 0.2 sec. it is found that the three-phase short-circuit kva. at 0.1 sec. is 3.7 times normal. It is

$$3.7 \times 8{,}000 = 29{,}600 \text{ kva.}$$

The short-circuit currents may be found as in the preceding problem.
